Ambulant Lewaschoff Treatment of Purulent Pleuritis. A. A. Kissel.—An apparently hopeless case of purulent pleurisy in a boy of 2, with high fever, great emaciation and a tubercular affection of the knee, was completely cured by the Lewaschoff method of the systematic substitution of warm saline solution for the pleuritic effusion. About 35 c.c. were removed in four applications of the aspirator, each followed immediately by the injection of the same amount of the salt solution. The fluid, which was a thin pus at first, was only slightly turbid at the last application. The procedure was repeated twice later, at intervals of about two weeks.

Beitraege z. Klin. Chirurgie (Tubingen), xxx, 2.

Intermittent Hydrops of the Knee. A. Linberger.—All of the 68 cases of intermittent hydrops of joints which Linberger has succeeded in collecting were in the knee, or knees, except one. Rheumatic antecedents were noted in 25, trauma in 8, gonorrhea in 4, the puerperium and tuberculosis in 2. Only 18 have completely recovered. The best results have been attained with arsenic—3 cures and 2 improvements out of 14; quinin—with 2 cures and 2 improved out of 18, and operation, which resulted in 4 cures of 7, and 3 improved although with recurrence later. Immobilization, ergotin injections in the vicinity, electricity, potassium iodid, a "dry diet" and change of occupation cured one patient each. No constant relation could be discovered between the recurrence of the effusion and menstruation. It is probably the result of inflammation, and consequently requires the same treatment, sparing the knee as much as possible. In the two personal cases observed, the hydrops recurred regularly every thirteenth day, with pain and inability to use the joint, conditions returning to normal in three days. One patient was a young man with a history of gouty attacks. The recurrence of the hydrops was postponed for six months at one time after puncture and disinfection. No benefit was derived from quinin, thyroid medication or Bier's stagnation hyperemia. [An English physician has recently called attention to a painless effusion in the right knee, liable to occur during the menopause or at puberty. It does not require local treatment, he says, as it subsides spontaneously.—Ed.]

Centralblatt f. Innere Med. (Leipsic), July 1.

Case of Three Lungs. G. Hernheimer.—At the autopsy of a three-weeks infant bifurcation of the trachea was noted, and a third lung was discovered communicating with it by a separate bronchus. All the three lungs showed the lesions of the fatal catarrhal pneumonia. Three other observations have been published of rudimentary lungs, but this is the first with actual functional connection with the trachea.

July 15.

Experimental Tuberculosis of the Suprarenals. B. de Vecchi.—Clinical conditions were imitated as closely as possible in the experimental research reported. Cultures of the tubercle bacillus were injected through the back into one suprarenal. All the animals exhibited the picture of severe intoxication, but no tubercular processes were found in the organs, merely the alterations in the cells of the nerves, liver, spleen and heart, and destruction of the blood with consequent deposits of pigment in the blood-forming organs, characteristic of severe intoxication. The most severe morbid changes were found in the central nervous system, indicating an elective action of the toxins on the gray matter of the cord. The entire cerebrospinal axis was affected, but the changes were most intense in the dorsal portion of the cord. The findings corroborate the assumption that Addison's disease is the sum of two factors: Insufficiency of the suprarenals and intoxication from the products resulting from the tubercular process developing in or outside of these organs. They also explain why caseous processes induce the classic picture of Addison's disease, while a tumor in the organ causes merely the indications of insufficiency.

Dermatologische Zeitschrift (Berlin), August.

Mechanism of Neurotic Alopecia. A. Bayet.—A young laboring man of a decided neuropathic tendency received a blow in the face. Three weeks later the hair fell out en masse over a large part of the head. Examination of the hairs showed that for 6 mm. from the proximal end each hair was degenerated, much diminished in diameter and with no traces of pigment. The hairs that did not fall out but continued to grow, showed the same shrinking and absence of pigment for a corresponding distance of 6 mm., while the hair was normal above and below the lanugo portion. The trauma must evidently have affected the nourishment of the papillæ for a time corresponding to the growth of 6 mm. of hair, after which conditions returned completely to normal.

Fortschritte a. d. Geb. d. Roentgenstrahlen (Hamburg), iv, 4.

Therapeutic Application of X-Rays. Sjögren.—Seventy-eight patients with various cutaneous affections have been treated at the writer's establishment in Stockholm. In 18 out of 27 cases of lupus the results were excellent. In 6 other cases the lupus had been treated in vain by other methods and was promptly and apparently permanently cured by radiotherapy. A complete cure followed its application in the 5 cases of scrofuloderma and 10 of chronic eczema, and also in 4 of intolerable pruritus of anus or vulva. All ulcerations were favorably influenced, fresh granulations rapidly developing while rodent ulcers shrank and finally disappeared. Hypertrichosis may require several repeated applications unless used with exceptional vigor from the start. Psoriasis did not seem to be affected by radiotherapy.

Jahrbuch f. Kinderheilkunde (Berlin), August.

Family Amaurotic Idiocy. Falkenheim.—A number of new cases have been published of Sachs' infantile family amaurotic idiocy with more or less paralysis, since his communications, raising the total to 64, of which 38 are known to have terminated fatally while the fate of 23 is unknown; 47 were seen by physicians and 17 diagnosed from others' descriptions. One of the first reported patients is still alive, 8 years old, but the affection is usually fatal before 3. Falkenheim has found 37 cases in 13 families, and notes that 4 of these families were interrelated. There did not seem to be any syphilitic, alcoholic or nervous antecedents in the family history, nor consanguinity, but the parents were Jews in the majority of cases. The development of the affection was not prevented by artificial feeding of the infants nor a wet nurse. No prophylactic measures have been discovered and no treatment has been of any benefit. The only consolation the physician is able to offer the parents is that they may have other children who will be free from the affection, as healthy children have been born before or after those thus afflicted in nearly every case. Falkenheim reports 4 new cases. The largest number—30—were observed in America, with 11 in England, 14 in Germany—generally Polish Jews—and 23 elsewhere on the continent. The symmetrical, congenital grayish-white opacity around the fovea, the weakness or paralysis of all the extremities, and the marasmus are the most striking features of this affection.

Wiener Klin. Wochenschrift, August 22.

Heart Failure from Insignificant Superficial Ulceration. Zuppinger.—In the three cases described, a small apparently insignificant ulceration was followed by death in a few days, with symptoms of insufficiency of heart action. The patients were healthy children between 1 and 3 years of age. The autopsy of two showed pronounced myocarditis and acute nephritis, evidently due to some severe intoxication, and from the absence of all other foci, the infection must have been exclusively localized in the superficial ulceration, a phlegmon on the foot in one case, an ulceration in the inguinal region in another and bilateral abscesses in the glands of the neck in the third. There were no symptoms of sepsis, merely those of cardiac insufficiency, rapidly fatal. The parents were healthy and had other healthy children in the two cases in which an autopsy was possible.

Gaceta Medica de Mexico, August 1.

Epilepsy in Mexico. S. Sosa.—This report was prepared at the request of Dr. Letchworth, president of the Association for the Study of Epilepsy. It states that there are 118 epileptic women and 48 epileptic men in the special wards set apart for them in the insane asylums of the City of Mexico. The treatment is usually bromids alternating with belladonna, a week at a time, with hydrotherapy. Various other methods of treatment have been tried with little result. Three Mexican plants, traditionally beneficial in epilepsy, were given partial trials. One, the *senecio canicida*, is an active poison for dogs, affecting the nervous centers and inducing a syndrome similar to that of epileptic grand mal. Toussaint discovered that this action was restricted to the protuberance and medulla oblongata. Various clinical experiments with it demonstrated that 10 to 20 cg. a day of the pulverized leaves diminished the number of seizures. Sosa administered it to ten women, but he noticed that cerebral congestion was easily produced while they were taking it. and he then abandoned its use. *Ipomca stans* is another plant which has for generations been credited with the power of curing epilepsy. It has never yet been really scientifically tested. The *indigofcra anil* was tentatively tried on account of its reputation for curing epilepsy, and Sosa states that its administration has a certain effect in diminishing the epileptic grand mal seizures, although it has never been tried on an effective scale.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Aug. 29 to Sept. 4, 1901, *inclusive:*

R. E. Austin, contract surgeon, leave of absence from the Department of Cuba, extended.

Alfred E. Bradley, captain and asst.-surgeon, U. S. A., ordered before a board in Washington, D. C., for examination for promotion.

Thomas S. Bratton, captain and asst.-surgeon, U. S. A., leave of absence extended.

Frederick A. Dale, lieutenant and asst.-surgeon, U. S. A., leave of absence granted.

Basil H. Dutcher, lieutenant and asst.-surgeon, U. S. A., ordered before a board in Washington, D. C., for examination for promotion.

Harry A. Eberle, contract surgeon, now at Canton, Ohio, is relieved from further duty at Aibonito, P. R., and on the expiration of his present leave of absence will report for duty at Fort Totten, N. Y.

Henry S. Greenleaf, lieutenant and asst.-surgeon, U. S. A., from Alcatraz Island, Cal., to duty at the Presidio of San Francisco, Cal.

Herbert W. Hatch, contract surgeon, former orders relieving him from duty in the Department of Alaska and directing him to proceed to San Francisco, Cal., en route for duty in the Division of the Philippines, revoked.

Franklin M. Kemp, lieutenant and asst.-surgeon, U. S. A., ordered before a board in Washington, D. C., for examination for promotion.

William P. Kendall, major and surgeon, U. S. A., to represent the Medical Department of the Army at the annual meeting of the American Public Health Association, to be held at Buffalo, N. Y., Sept. 16 to 20, 1901.

Edward L. Munson, captain and asst.-surgeon, U. S. A., to represent the Medical Department of the Army at the annual meeting of the American Public Health Association, to be held at Buffalo, N. Y., Sept. 16 to 20, 1901.

Harry O. Perley, major and surgeon, U. S. A., now at San Francisco, Cal., will proceed to Plattsburg Barracks, N. Y., for duty at that post.

Frederick P. Reynolds, captain and asst.-surgeon, U. S. A., leave of absence granted.

Herbert G. Shaw, lieutenant and asst.-surgeon, U. S. A., from the Presidio of San Francisco, Cal., to Alcatraz Island for post duty.

Richard P. Strong, lieutenant and asst.-surgeon, U. S. A., leave of absence extended.

Benjamin L. Ten Eyck, captain and asst.-surgeon, U. S. A., ordered before a board in Washington, D. C., for examination for promotion.

Philip G. Wales, captain and asst.-surgeon, U. S. A., ordered before a board in Washington, D. C., for examination for promotion.

Roy A. Wilson, contract surgeon, from Fort Totten, N. Y., to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Navy Changes.

Changes in the Medical Corps of the Navy, week ended Sept. 7 1901:

Asst.-Surgeon E. Thompson, detached from the *Solace* and ordered home and to wait orders.

Medical Director E. S. Bogert, retired, detached from the Bosto Navy Yard, September 5, and ordered home.

Surgeon I. W. Kite, detached from the *Monterey*, upon reportin *of relief, and ordered* home and to wait orders.

Surgeon V. C. B. Means, detached from the marine recruitin rendezvous, September 25, and ordered to the *Monterey* as relie of Surgeon I. W. Kite, sailing from San Francisco, Cal., by Arm transport about October 1.

Surgeon G. T. Smith, ordered to the *Amphitrite* as relief o Surgeon J. M. Edgar.

Surgeon J. M. Edgar, detached from the *Amphitrite*, upon reporting of relief, and ordered home and to wait orders.

Asst.-Surgeon E. O. Huntington, ordered to the Naval Hospital New York.

Asst.-Surgeon J. F. Murphy, detached from the Naval Academy *upon reporting of relief*, and ordered to the *Indiana*.

Asst.-Surgeon W. M. Garton, detached from the *Indiana* an ordered to the Naval Academy as relief of Asst.-Surgeon J. F Murphy.

Medical Director G. F. Winslow, ordered to the naval recruitin rendezvous, Boston, Mass., October 1.

Surgeon C. J. Decker, ordered to the marine recruiting rendezvous, San Francisco, Cal., September 25, as relief of surgeon V. C B. Means.

Asst.-Surgeon P. E. McDonald, detached from the Naval Museu of Hygiene, Washington, D. C., September 9, and ordered to th *Constellation* as relief of Asst.-Surgeon C. A. Crawford.

Asst.-Surgeon C. A. Crawford, detached from the *Constellation* upon reporting of relief, and ordered to the Naval Hospital, Chelsea, Mass., as relief of Asst.-Surgeon R. R. Richardson.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissione and non-commissioned officers of the U. S. Marine-Hospital Servic for the seven days ended Sept. 5, 1901:

P. A. Surgeon J. O. Cobb, granted ten days' extension of leav of absence.

P. A. Surgeon Rupert Blue, granted leave of absence for te *days from* Sept. 2, 1901.

P. A. Surgeon J. H. Oakley, granted leave of absence for tw months from Sept. 17, 1901.

Asst.-Surgeon H. C. Russell, to proceed to Cleveland, Ohio, an assume temporary command of service during absence of Surgeo W. J. Pettus.

Asst.-Surgeon H. B. Parker, *to proceed to Amite City and Abit* Springs, La., for special temporary duty.

Asst.-Surgeon M. K. Gwyn, granted leave of absence for one day

Asst.-Surgeon B. S. Warren, granted leave of absence for fourteen days from Sept. 14, 1901.

A. A. Surgeon P. N. Barnesby, granted leave of absence for on month from Sept. 1, 1901.

A. A. Surgeon R. E. Ebersole, granted leave of absence for seven days from Sept. 3, 1901. Paragraph 181, Regulations, M.-H. S.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Sept. 7, 1901:

SMALLPOX—UNITED STATES.

California: Los Angeles, Aug. 17-24, 1 case; San Francisco, Aug. 18-24, 2 cases.
Kansas: Wichita, Aug. 24-31, 1 case.
Louisiana: New Orleans, Aug. 24-31, 1 case.
Massachusetts: Boston, Aug. 24-31, 6 cases.
Minnesota: Minneapolis, Aug. 17-24, 5 cases.
Nebraska: Omaha, Aug. 24-31, 2 cases; South Omaha, Aug. 23-30, 2 cases.
New Jersey: Newark, Aug. 24-31, 5 cases, 2 deaths.
New York: New York, Aug. 17-31, 37 cases, 12 deaths.
Pennsylvania: Philadelphia, Aug. 24-31, 31 cases, 2 deaths.
Utah: Salt Lake City, Aug. 19-24, 2 cases.
West Virginia: Wheeling, Aug. 18-31, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, Aug. 10-17, 1 case.
Brazil: Rio de Janeiro, July 28-Aug. 4, 42 deaths.
Colombia: Panama, Aug. 19-26, 10 cases.
France: Paris, Aug. 3-17, 19 deaths.
Great Britain: Dundee, Aug. 10-24, 4 cases; London, Aug. 10-17. 13 cases, 2 deaths.
India: Bombay, July 30-Aug. 6, 2 deaths; Calcutta, July 27-Aug. 3, 5 deaths; Madras, July 27-Aug. 2, 9 deaths.
Italy: Messina, Aug. 10-17, 7 cases, 1 death; Naples, Aug. 10-17, 119 cases, 17 deaths.
Mexico: City of Mexico, Aug. 18-25, 2 cases.
Russia: Moscow, July 27-Aug. 10, 4 cases, 3 deaths; Odessa. Aug. 3-17, 2 cases, 1 death; Warsaw, July 27-Aug. 10, 5 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, July 14-23, 7 deaths.
Colombia: Bocas del Toro, Aug. 21, 1 case.
Costa Rica: Port Limon, Aug. 11-18, 8 cases, 4 deaths.
Cuba: Cumanayagua, Aug. 17-24, 1 case; Matanzas, Aug. 31, 2 cases.

CHOLERA.

India: Bombay, July 30-Aug. 6. 8 deaths: Calcutta, July 27-Aug. 3, 17 deaths; Madras, July 26-Aug. 2, 26 deaths.
Japan: Yokohama, July 20-Aug. 3, 2 cases.
Straits Settlements: Singapore, July 6-13, 1 death.

PLAGUE.

Brazil: Rio de Janeiro, July 14-28, 4 deaths.
China: Hongkong, July 13-27, 37 cases, 35 deaths.
India: Bombay, July 30-Aug. 6, 158 deaths; Calcutta, July 27-Aug. 3, 11 deaths.

AN IMPROVED METHOD OF TREATING HIGH-SEATED CANCERS OF THE RECTUM.*

ROBERT F. WEIR, M.D. (Hon.) F.R.C.S. Eng., C.F.S.C. Paris.
Professor of Surgery, College of Physicians and Surgeons, Columbia University, N. Y.; President New York Academy of Medicine.
NEW YORK CITY.

Many will agree with me, I fancy, in considering the Kraske operation a very unsatisfactory one for the removal of the high-seated cancers of the rectum. In addition to the depth of the wound, the more or less jagged invasion of the peritoneal cavity, the possible difficulty of satisfactorily drawing down the upper portion of the bowel, and, finally, the trouble that is involved in the proper suturing of the preserved anal portion to the proximal end, all render it, with its annoying hemorrhage, *an operation that is often*, in my judgment and experience, troublesome and devoid of surgical neatness and precision. It is true that within four or five inches from the anus the affected part of the bowel can be easily reached and removed with the creation, if the anus is involved, of a fairly satisfactory sacral artificial anus. But if the anus, and say two inches of the adjoining rectum, can be saved, a point which is of great importance to the subsequent comfort of the patient, and to do which the bowel above must be liberated and brought down, then the foregoing objections to the surgical procedure in vogue must be taken strongly into consideration. They apply as well to the methods of approach from behind, as in Kraske's method, or from the front (by the vagina), as Murphy has recently advised. The latter I have not essayed, but an experience of over 20 cases of Kraske's resection, 9 of which were followed by an attempt at union of the divided rectal ends, has markedly impressed me with the desirability of attacking highlying cancer of the rectum by a somewhat different method. The abdominal route has been tried by others but last year, i. e., in January, 1900, I ventured to practice such an extirpation after the plan that Maunsell[1] (then of New Zealand) had advised. His suggestion, as you may remember, was, to open the abdomen above the pubis, separate the peritoneum from the bowel largely and then to pass a loop of tape by a long mattress needle from the opened pelvis through the rectum and out the previously enlarged anus. By this loop he proposed to pull down the neoplasm loosened by peritoneal divisions and by some additional blunt dissection with the finger, so that it would appear at the anus, everting the lower part of the rectum as it protruded. If the protrusion was accomplished, and to do this it might be necessary to acquire more room by freely dividing the anus back to the coccyx, then the tumor was removed and the two ends of the bowel now, so to speak, out in the cold world, were easily connected by sutures and then replaced. The final step was the suturing of the divided peritoneum. This was a finely conceived operation, but it did not work with me in my trial of it, the hitch being that the tumor would not pass through the divided anus and that the forcible traction enlarged the tape openings into the bowel so much that escape of its contents was possible. I therefore changed the plan of procedure in this way: My fingers had freely detached the divided peritoneum so that the bowel and the entire contents of the sacral curve were liberated behind nearly to the tip of the coccyx and in front to the edge of the prostate; this gave me room to tie around the bowel, some three inches from the anus, a couple of iodoform tapes, about an inch apart. The intestine was here cut through and, being free, was readily raised out of the abdominal wound and held aside by an assistant. The lower end of the rectum was then seized by a forceps in the hands of another assistant, who drew it down and out of the anus in an everted condition. Untying the tape that closed this everted bowel, its lumen was opened so that a longer forceps could be carried through it into the pelvis, when the end of the upper bowel was brought down within its clasp and by it the latter was drawn through the lower bowel out into the world. A couple of needles passed through the invaginated ends of the bowel—near their margins—allowed easy union by sutures of their edges (with the knots inside the bowel) and replacement of the same followed. After the peritoneum had been sewn together and to the bowel so that the pelvis and general abdominal cavity had been separated one from the other by a peritoneal shelf, I deemed it best to provide drainage from the peri-intestinal space below by a tube introduced from just in front of the coccyx. These details will be better understood on inspection of Figs. 1 to 4.

The outcome made a delightfully satisfactory operation, and its success justified its repetition in two other recent cases, reports of which are here appended. Two of these patients recovered and one died, not from any peritonitis, but from a persistent diarrhea without temperature elevation. In the two that recovered inspection shows no recurrence eighteen months and nine months, respectively, after the operation. It was necessary in each case, some three to six weeks afterward, to use a No. 7 or 8 Wales rectal bougie, for there was somewhat more stenosis than is seen in the reunion of peritoneally covered bowel ends. This, however, was to be expected in a measure. The patients are well and in good health, and have one or two movements daily with ease. Some points are worth touching on a little more fully.

---

* Read at the Fifty-second Annual Meeting of the American Medical [illegible] Section on Surgery and Anatomy, and approv[illegible] the Executive Committee of the Section: W. J. [illegible], and A. J. Ochsner.

[1] Lancet, Aug. 27, 1892.

1. Concerning the Division of the Peritoneum.—By drawing the neoplasm backwards the folds of the peritoneum stretching from the bladder in the male, and from the uterus in the female, are rendered prominent and a small cut is made in each, and through these openings a scissors curved on its side or the common bandage scissors can be introduced just under the peritoneum and this divided up to the bowel, across, and behind it. A transverse cut across the front of the bowel joining the two knife punctures frees the bowel entirely and by pushing downwards anteriorly the prostate is soon reached. Before, however, peeling off the sacral tissues I have found it advantageous to search for and to tie the superior hemorrhoidal artery, as this renders the operative field nearly bloodless. This exposure of the sacral curve can be carried much further upwards should necessity arise, in a hunt for enlarged glands. If the lower blade of the scissors is kept persistently against the under surface of the peritoneum no risk of damage to vessels, nerves, etc., will be experienced.

2. As to Surgical Cleanliness.—The risk of this and similar procedures is, of course, the possible abdominal sepsis from the divided ends of the bowel. I have not only exercised particular care in this respect, but have, as soon as the lower division has been accomplished, touched the divided exposed mucous membranes with pure carbolic acid, which is promptly swabbed off with alcohol, and similarly treated the upper divided gut as it rests outside the abdomen. Prior to putting in the final sutures and while the bowel ends protrude from the anus this cauterized portion is cut off also. After the eversion of the lower bowel the whole pelvis is repeatedly washed with sterile salt solution, the parts being under good exposure by the retraction of the intestines above by pads or by a broad wire-handled retractor covered by gauzes, three inches by eight inches, which admirably keeps them back like a diaphragm. I prefer this to the diaphragm that Maunsell originally proposed (loc cit).

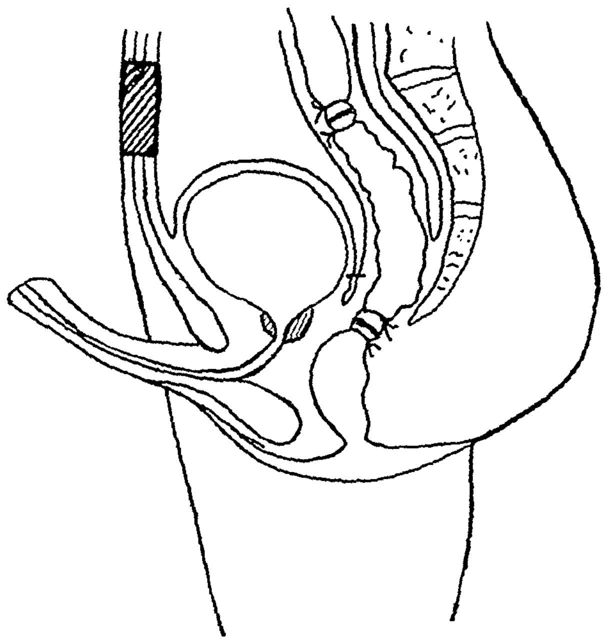

Fig. 1.—Tying off the tumor through an abdominal incision, after separating peritoneum from sacrum and bladder.

3. The Anus and the Drainage.—In my first case, to enable me to extract the neoplasm by traction, I freely divided the anus backwards with a somewhat prolonged impairment of power. In the other two cases only stretching in the usual way was resorted to. In all the [illegible] rt drainage tube was carried up to the site of the line of suture and inside the bowel was placed a small rubber tube covered with iodoform gauze.

The contrast in this operation of Maunsell, which I have only slightly modified, with the usual Kraske operation, is most marked. Its signal precision, its freedom from hemorrhage and its thorough exclusion of the area of trauma from the peritoneal cavity lead me to hope that it may come into more general use, as it conduces to the desired end in such diseases, which is, more thoroughness in their extirpation.

It is especially important to have a reliable assistant in this procedure. He should evert the lower bowel, pull down the upper, conduct the suturing, replacement and drainage. The surgeon in charge had better restrict himself to the interior abdominal work and thus be able to maintain the required asepsis. It is true that the use of rubber gloves, easily disinfected as they are, or so readily changed, will often do away with this need.

Case 1.—Mr. C. H., aged 64. Referred to me by Dr. Knickerbocker in January, 1900, with the history of pain in the lower bowel for over a year, with constipation increasing in character with occasional attacks of obstruction. Loss of flesh moderate, not more than ten pounds. Some loss of strength. No anemia.

By examination a carcinomatous mass can be felt about four inches from the anus. Into this the tip of the forefinger can be passed sufficiently to enable one to prove that the mass above can be moved quite freely. The upper end of the neoplasm can not be reached. Its nature was confirmed by a microscopic examination.

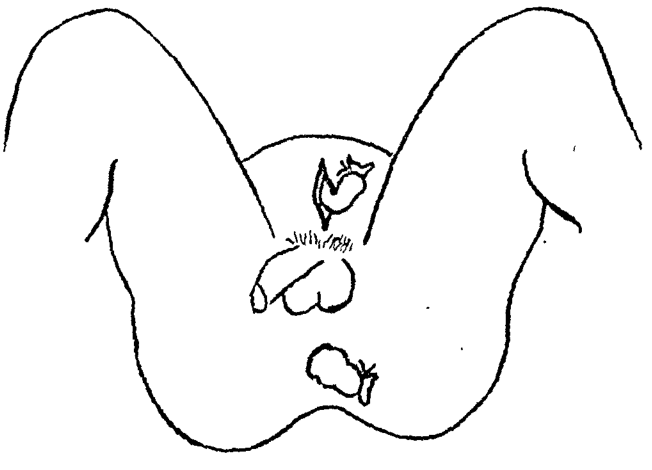

Fig. 2.—Lower end of rectum everted through the anus and the upper end of bowel drawn out of the abdominal cavity.

On Jan. 30, 1900, rectal extirpation by Maunsell's method by abdominal section was attempted with the assistance of Drs. Frank Hartley, Foote and Taylor. Nitrous oxid gas with oxygen was administered by Dr. Goldan.

The bowels had been freely moved on the day previously, as I do not like fecal flooding at the time of operation. After the abdomen was opened a transverse septum 3 by 8 inches of gauze stretched on stout copper wire with a handle was used to retain the small intestines above the pelvis. It answered its purpose very well. The peritoneum was cut through on each side of the rectum back to the sacrum and also across just behind the bladder. The contents of the sacral curve were peeled off after tying the superior hemorrhoidal artery. Several small glands were found here. None could be found above the upper limit of the peritoneal division. An attempt was made by a loop of tape drawn through the upper part of the tumor out through the anus to pull down the growth, but this failed though the anus had been enlarged and the rectum itself previously dilated by Dr. Hartley by means of specula and fingers. The tugging not only failed, but tore the gut badly and was abandoned as impracticable. Therefore, a tape of iodoform gauze was applied around the rectum below the tumor and a clamp was fastened just above this. On dividing the intervening intestine the tumor was able to be lifted outside the abdominal cavity after a little further liberation of the peritoneum covering the mesentery. The tumor which was four inches long, that is to say, its upper limit was 8 to 9 inches from the anus, was cut off and the tied end of the bowel remaining was sterilized by pure carbolic acid, as was also the anal end of the rectum left in the pelvis. Dr. Hartley now, with a forceps, seized the lower portion of the bowel and everting it caused it to protrude through the anus. Another introduction of the forceps through the everted gut caught the end of the upper bowel and this in turn was drawn through the everted anal portion. Both ends of the rectum were held *in situ* for a time by two long straight needles passed across their wall at right angles near the suture line, which was freshened by cutting off the cauterized edge. Between 20 and 30 interrupted fine chromicized catgut sutures were used to close the circumference of the bowel. The united portion was then drawn up into position by slight traction from Dr. Weir. After this the divided peritoneal edges were carefully sewn together by interrupted sutures, first freely irrigating the raw pelvis, which was drained from below by a drain inserted thither through the wound reaching to the coccyx. The operation lasted over three hours by reason of the time spent in endeavoring to pull down and drag out the tumor in accordance with Maunsell's directions. The patient had no shock, but was found to have on coming out of his anesthesia a complete muscular and sensory paralysis of his entire left arm. During the anesthesia both arms had been fastened above his head, which latter, moreover, for ease of working the somewhat cumbrous apparatus of the mixed anesthesia, had been kept strongly to the right side, thus all the more stretching the brachial plexus. It may be said that it required some six months for him to recover from this, my first experience in position paralysis. His recovery from the operation was satisfactory and prompt. He was up and about in three weeks, a slight mural abscess delaying a little his progress. He noticed at the end of six weeks some little trouble in defecation, and I found on examination that a cicatricial contraction linear in character had occurred which yielded to a No. 3 to No. 8 Wales bougie in the course of a month. Since then he has been in good local and general condition.

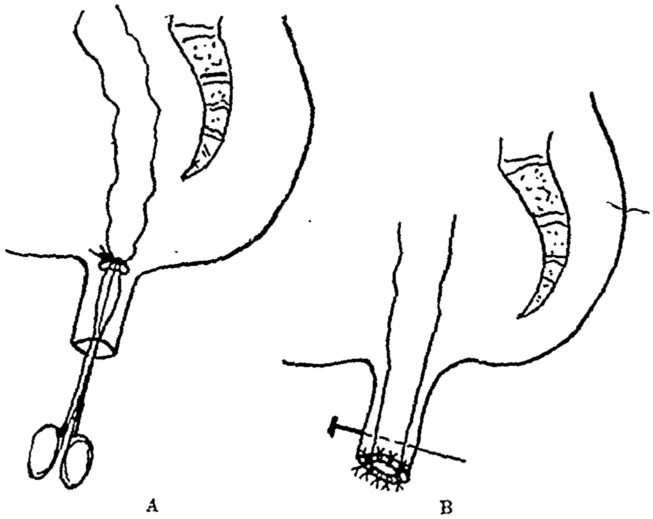

Fig. 3.—A. The upper bowel drawn out through the everted lower end of rectum. B. The ends of the two portions of the rectum sewn together.

CASE 2.—Mrs. A. H. T., admitted to Roosevelt Hospital, Oct. 17, 1900, with this history: She began six months ago to have blood and mucus preceding stools, which continued up to time of admission without any considerable increase. Six weeks ago pain was felt deep in the pelvis, which was not increased by defecation; aching in character but worse at times. No diminution in size of fecal mass. Bowels regular. Slight loss of flesh.

Examination showed general condition good. Rectal: 3½ inches from anus an ulcerated mass 1½ inches in width attached to anterior and left side in a sessile manner; finger can not reach above it; slightly tender; not markedly hard; no constriction. No glands felt. No bleeding from examination. Rectum slightly movable. Microscopic confirmation of carcinoma.

Operation.—Oct. 27, 1900, anesthetic, gas and ether. Trendelenburg position. Celiotomy in median line; intestines retracted upward by 3 by 8 inch gauze-covered retractor. Tumor found movable and running upwards and involving the upper part of rectum and lower part of sigmoid. Peritoneum divided on each side of diseased gut; 4½ inches excised between ligatures. Distal stump invaginated through *rectum* and anus. Ligature removed; proximal stump then drawn through everted distal portion; a circular enterorrhaphy done outside rectum. Gut retracted into abdominal cavity again; peritoneum sutured over it. Abdominal wall closed. Drainage posterior to anus. Operation almost bloodless. Glands in hollow of sacrum not much involved.

Course.—Uneventful recovery; bowels moved ninth day; all drains removed and wounds healed by fourteenth day; slight discharge of muco-pus from rectum for two weeks more.

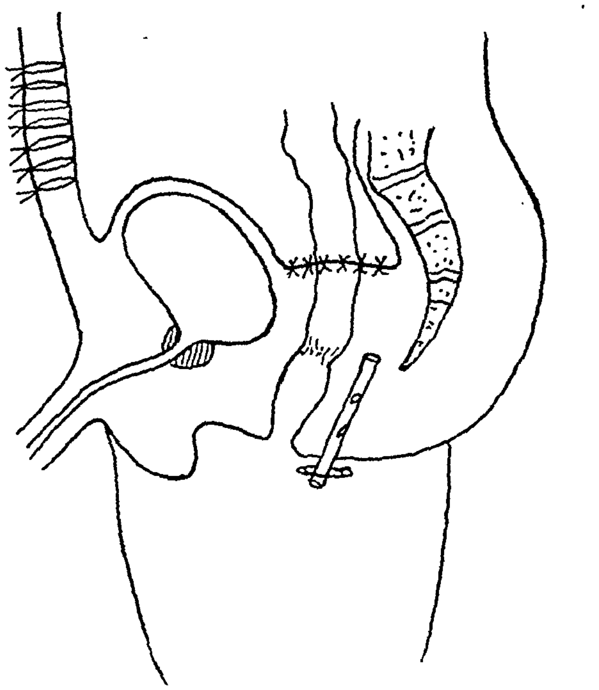

Fig. 4.—The united bowel replaced with posterior drainage, and the divided peritoneum so sewn together as to shut off the general peritoneal cavity from the pelvis.

Developed mild pneumonia then, transferred to medical side from which discharged improved, Dec. 20, 1900. Three months after operation a smooth stricture felt of some thickness, admitting No. 6 and 7 Wales bougie. Movements twice a day. In good general health when seen in May, 1901.

CASE 3.—Man, 54, sent to me by Dr. Forman, of Freehold, N. J., with a history of rectal trouble going back many months. from about 2½ inches from the anus upwards so that deep above pubis its impulse from below could be felt. Was only in fair condition. The operation was done in the manner previously described, but it varied in two ways. There was much more than the usual oozing of blood, and after opening the peritoneum and separating the wall it was found that the infiltration of the carcinoma extended along the right lateral wall toward the anus so that there was at this point not more than 1 to 1½ inches of sound intestinal wall. This in its eversion demanded its truncation and also additional loosening of the upper bowel from its mesentery. The other steps were as usual. He did well for twenty-four hours and then began to have a diarrhea without pain or vomiting or distension, which was not controllable, and which brought about a fatal issue at the end of the fourth or fifth day.

THE PRESENT STATUS OF THE CARCINOMA QUESTION.*

N. SENN, M.D., C.M., Ph.D., LL.D.

Professor of Surgery, Rush Medical College, in Affiliation with the University of Chicago; Surgeon-in-Chief, St. Joseph's Hospital; Attending Surgeon, Presbyterian Hospital; Professorial Lecturer on Military Surgery, University of Chicago.

CHICAGO.

There is no subject in pathology and surgery that has been studied with more care and diligence during the last two decades than the carcinoma question. The most intense interest in this subject was awakened with the origin and development of the modern science of bacteriology. As soon as it became known that all inflammatory processes are caused by specific pathogenic micro-organisms, it was natural that by reasoning from analogy the conclusion was reached that carcinoma is a parasitic disease. There are so many similarities between chronic infective diseases, notably tuberculosis and carcinoma, that we can readily appreciate the motives that led to the investigations in all parts of the civilized world concerning the microbic origin of carcinoma. Various methods of tissue staining, cultivation and inoculation experiments have all been utilized by thousands of earnest investigators in their efforts to discover the essential microbic cause of carcinoma. Numerous intracellular and extracellular bodies have been discovered and described as the specific parasitic cause of carcinoma, but for none of them has the claim been substantiated by the crucial tests. Searching criticisms from different reliable sources have shown almost conclusively that these bodies are not living organisms, but the products of degeneration of the cell protoplasm of cell inclusions of a non-parasitic nature. From an etiologic standpoint, very little has been added to our knowledge since the epoch-making labors of Virchow, Cohnheim and Waldeyer.

Something has been gained by the study of tumors in plants and in the lower animals in contributing to our knowledge of the etiology and pathology of tumors in general. Pathologic processes in plants are much simpler than in animals, owing to the absence in the former of many complicating factors, such as nerves and blood vessels; at the same time, the plants are constructed upon a much simpler embryologic plan. Both animal and vegetable cells have in common the nitrogenous carbon compound called "protoplasm." The idea of carcinoma being a local manifestation of a general dyscrasia has been abandoned years ago. Virchow established by his immortal researches that great pathologic law, *omnis cellula e cellula,* which applies with special force to the origin and growth of carcinoma, as well as other tumors, and the histogenesis of all inflammatory swellings. Students of this subject are now all agreed upon the fact, well established by the most accurate and painstaking microscopic investigations, that carcinoma, in all its histologic and clinical varieties and in the different anatomical localities where it originates, is a local disease, and that generalization only takes place by metastasis from the primary tumor.

Pathology has been materially advanced by careful microscopic work concerning the origin, growth, multiplication and life-history of the carcinoma cell and its manner of local and general dissemination. The atypical irregular mitotic figures which are seen in the segmenting carcinoma cell are in strong contrast with the regular symmetric mitosis observed in indirect cell division in normal tissue. The metastatic processes have been traced step by step through the lymphatic channels and the systemic circulation, and it has been demonstrated beyond all doubt that the secondary tumors are the direct offspring of migrating carcinoma cells from the primary tumor, and that the pre-existing tissues take no part in the tumor formation, primary or metastatic. With these few exceptions, the enormous energies expended in determining the true nature of carcinoma have yielded very little of scientific or practical value.

From these introductory remarks we can formulate the first proposition.

Proposition 1: The most notable contributions to the present status of the carcinoma question are to be found by the *investigations which have thrown new light on the origin, growth, segmentation* and *manner* of local and general dissemination of the carcinoma cell.

Definition.—The definitions of carcinoma must necessarily vary in accordance with the idea entertained by the author or speaker regarding the nature of the disease. That no unanimity has been reached in defining carcinoma becomes very evident in the perusal of the most recent literature on the subject of tumors.

"A tumor is a new formation of tissue possessing atypical structure, not exercising any function of service to the body, and presenting no typical limit of growth." —Ziegler.

The following is very similar: "A tumor proper is a mass of cell tissue or organs resembling those normally present, but arranged atypically. It grows at the expense of the organism, without at the same time subserving any useful function."—C. P. White.

An allusion to absence of function in any definition of carcinoma is superfluous, as the most characteristic clinical feature of this tumor consists in progressive destruction of tissues regardless of their anatomic structure and physiologic function.

Author's definition: "Carcinoma is an atypical proliferation of epithelial cells from a matrix of embryonic cells of congenital or post-natal origin."

This definition includes what is known of the histogenetic origin of carcinoma. It refers the tumor to its primary location in mesoblastic tissue, and the origin of its cellular elements to a matrix of embryonic epithelial cells. In 1846 Pigué explained the occurrence of congenital tumors by inclusion of embryonic remains, a process he termed *diplogenesis.* Remak, in 1851, distinguished the three germinal layers and believed the epithelial cells were the histologic origin of carcinoma. In 1855 Cruveilhier described an enchondroma of the hand, and traced its origin to an imperfect ossification of cartilage at the site of tumor formation. In 1860 Heschl gave a description of the origin of dermoid tumors in the orbital region, neck and perineum, which he claimed were the products of inclusions derived from the epiblast. The theory of embryonic tumor germs was placed upon a scientific basis by Durante in 1874, and a year later by Cohnheim, a theory so warmly championed by Waldeyer and other contemporaries. The heterotopic location of the epithelial cells distinguishes carcinoma from all the benign epithelial tumors. Atypical proliferation of epithelial cells means their growth and multiplication in a locality where epithelial cells have no legitimate citizenship. The matrix may occupy a vascular location from the very beginning, when embryonic epithelial cells have been displaced into mesoblastic tissue during the development of the embryo in the case of congenital matrices; or when in a burn or wound or an inflammatory process embryonic cells become buried in the mesoblast after injury, or destruction of the membrana propria in matrices of post-natal origin; or, finally, if the matrix is confined to the epiblastic or hypoblastic embryonic layer, the carcinoma dates back to the time when the embryonic cells passed through and beyond the membrana propria into the vascular mesoblastic tissues. The above warrants us in framing

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: W. J. Mayo, H. O. Walker, and A. J. Ochsner.

Proposition 2: Carcinoma is a tumor resulting from an atypical proliferation of epithelial cells from a matrix of embryonic cells of congenital or post-natal origin.

Origin and Histogenesis of Carcinoma.—The first attempt to trace tumors to their legitimate histogenetic source was made by Virchow, who believed that the carcinoma cells, like the cells of nearly all tumors, were derived from the connective tissue. He found epithelial cells far away from their normal location, and from their resemblance to epithelial cells he called them epitheloid cells. He believed that these cells were produced in the localities in which he found them. Virchow's theory predominated, until Remak established the doctrine of the independence of the different histologic elements, and founded the law of the normal succession of cells, which has remained firm and unaltered up to the present time. In the light of recent embryologic investigations, the doctrine of metaplasia, as expounded by Virchow and his contemporaries, is no longer tenable. Connective tissue can not produce epithelial cells, and epithelial cells are never transformed into connective tissue; hence,

Proposition 3: The law of the legitimate succession of cells holds true in the origin and growth of tumors, both benign and malignant, as well as in the production of normal and inflammatory tissue.

Barfurth takes the position that tumors originate before and after birth from a partial or complete separation of cells or groups of cells from their organic connections, traumatism being an influence capable of causing the epithelial metastasis. The separated cells, no longer subject to the restraining influence of their normal connections, and still receiving an adequate nourishment, grow and form tumors which, according to the size and organization of the segregated mass, correspond in general structure with the organ from which they are derived, sometimes more, sometimes less.

A somewhat similar view is entertained by Adami, only he presents the subject in a stronger light, and bases upon it a new theory of tumor formation which he calls "habit of growth." This theory presents many convincing points. He says: "Briefly, this theory is based on the fact that cells and their descendants, which for long periods have been subjected to certain influences whereby their properties and structures have become modified, eventually retain those properties after the influences referred to have ceased to act upon them. I base it again upon that principle of inertia already indicated—a principle which some years ago (1896) in this connection I referred to as the 'habit of growth.' Whatever the origin, therefore, of the tumor proper, however it started, what makes the tumor is the assumption by the primary cells of that tumor of the habit of work, and according to the extent of this replacement, so do we set the various grades of tumor formation from the most benign to the most malignant."

Fabre-Domergue's theory of the nature of epithelial tumors is based on the supposition that from the most benign papilloma and adenoma to the most virulent carcinoma they all constitute an uninterrupted chain of genetic processes, the same only gradually varying tumors. The slightest disorganizations of the normal behavior are shown by the papillomata and adenomata, which he terms "entheliomata"; to these are added without any sharp lines of distinction the more disorganized epitheliomata and carcinomata. The cause of the abnormal growth is the *"disorganisation cellulaire,"* that is, the displacement of the axis and segmentation direction of the cells to the basal membrane. In a normal condition the nuclear karyokinetic figures stand perpendicular to the basal membrane, so that the equatorial plates form a parallel layer to the basal membrane. If segmentation takes place in another direction, it is an indication of tumor growth. This theory is a short-lived one, and I doubt if any other observer has made the same distinction between such karyokinetic processes in normal and tumor cells.

Ribbert maintains that carcinoma does not begin in the penetration of epithelial cells into the connective tissue, as taught by Thiersch and others, but from the growth of the subepithelial connective tissue. This subepithelial connective tissue proliferation elevates the epithelial cells, disturbs their proper anatomic relation, and envelops them in connective tissue; and these cells then continue to grow in the direction of least resistance, that is, in the lymphatics and connective tissue spaces. Hauser, with most modern pathologists, takes the opposite ground. He has observed during the very early stages in the growth of carcinoma of the stomach the epithelial lining hypertrophied and continuous with the submucous epithelial infiltration composed of cells of the same structure. The writer has seen numerous specimens of epithelial carcinoma of the skin presenting an identical picture during the very earliest stages of tumor growth. The connective tissue proliferation takes place later, secondarily, after the epithelial cells have invaded the vascular tissue. The earliest stage in the development of a carcinoma is invariably an active proliferation and migration of epithelial cells.

As carcinoma is always developed from a matrix of epithelial cells, and only embryonic cells possess migrating power, we are prepared to defend

Proposition 4: As carcinoma always originates from epithelial cells, primary carcinoma in mesoblastic tissue is impossible from a histogenetic standpoint, unless a *matrix* of embryonic epithelial cells has become displaced during the development of the embryo, or when embryonic epithelial cells have become buried in mesoblastic tissues, after birth, by injury or disease.

W. R. Williams very correctly opposes the parasitic origin of carcinoma from the difference in the histologic structure of the cells which constitute the mass in carcinoma, and inflammatory products. Carcinoma differs morphologically, according to the structures whence it originates, and which it resembles histologically, as seen in the different organs; while inflammatory products present the same structure independent of their anatomic location or character of tissue involved. The great resemblance between the primary and secondary tumors could not be explained as the product of an inflammatory process. The writer has had numerous opportunities to examine specimens during the very earliest stages of glandular involvement, and has never failed to find as the nucleus of secondary tumor formation a group or groups of epithelial cells, which resembled invariably in every respect the cells in the primary tumor. These facts afford sufficient ground upon which to base

Proposition 5: The histology and histogenesis of carcinoma speak against the parasitic origin of this disease.

Nearly all pathologists take it for granted that the stroma of carcinoma consists of the pre-existing connective tissue fibers and their descendants. Epithelial cells in normal and pathologic conditions are never converted into connective tissue. Carcinoma begins as an infiltration of the vascular connective tissue by migrating embryonic epithelial cells; hence the only source for the stroma is the connective tissue.

Williams, of Baltimore, finds that when the reticulum of the carcinoma is of new formation, it is usually devoid of elastic tissue fibers. The tumors in which newly-formed elastic fibers occurred either contained a large amount of connective tissue stroma, or the newly formed fibers were in connection with pre-existing elastic elements of the original tissue involved by the tumor. These, as well as numerous similar observations, lead to

Proposition 6: The stroma of carcinoma consists of pre-existing connective tissue fibers and their descendants.

Asymmetric Karyokinesis in Carcinoma Cells.—The exaggerated vegetated capacity of carcinoma cells, as compared with the productive power of the cells of normal tissue, suggests irregular karyokinesis. Ferris has made an elaborate study of the morphologic changes in the cells in carcinoma. The most important of his observations shows that bipolar mitosis is more indicative of malignancy than the multipolar. The production of multipolar and asymmetric mitosis by chemic agents seems to suggest that a faulty chemistry may be a factor in the etiology of carcinoma. Hypochromatic and asymmetric mitosis are found usually only in carcinoma. Their presence, therefore, may prove of considerable diagnostic value.

Nedjelsky made an extended investigation of cell division more especially as it occurs in carcinoma. According to this observer, cells multiply by karyokinesis and by direct segmentation. In neither sarcoma nor carcinoma did he find any exclusive form of amitotic cell division, and in all pathologic processes various forms of amitotic cell division may be seen. In some of the tumors, particularly in an ovarian carcinoma, the author found both mitotic and amitotic segmentation.

Different types of pathologic karyokinesis were discovered in the tumor tissues studied. Amitotic cell division is initiated by an active increase in the size of the nucleolus which gradually segments. In some instances the nucleolus divides simultaneously into several new nucleoli. The division of the nucleolus is connected with that of the nucleus, the process, as a rule, being that the nucleolus lies at right angles to the long axis of the nucleus and approaching the walls of the latter, as it elongates, eventually fusing with it. The segmentation of the nucleus is often asymmetrical. The study of atypical cell division in tumors deserves accurate and more extended study.

Hemmeter places great weight on pathologic mitosis as an indication of malignancy. In carcinoma of the stomach he believes that a correct diagnosis can be made by microscopic examination of segments of tissue in the stomach contents by observing the presence of pathologic mitosis, more especially if with this condition the existence of atypical formation of tubules can be demonstrated. It is now a well-established fact that the carcinoma cells multiply by mitosis (Flemming), karyokinesis (Schleicher), nuclear segmentation (O. Hertwig), cytodiaresis (French authors). The process of segmentation as observed by different pathologists is usually atypical.

Pianese has made the most exhaustive study of the structural changes which take place in the epithelial cells in carcinoma during segmentation. He describes:

1. Comparatively typical, bipolar symmetrical mitosis. *a.* Hyperchromato-mitosis, hypochromato-mitosis. *b.* Giant mitosis.
2. Atypical mitosis. *a.* Pluripolar, atypical mitosis. *b.* Atypical, asymmetrical mitosis.
3. Abortive mitosis.

The above recent researches concerning the manner of cell division in carcinoma support

Proposition 7: Carcinoma cells usually multiply by irregular, atypical karyokinesis, and this pathologic segmentation is an important indication of malignancy and as such is of considerable diagnostic value.

Local Growth.—One of the most conspicuous clinical features of carcinoma is its progressive extension *in loco.* The primary tumor grows at the extreme of the adjacent tissues, regardless of their anatomic structure. It respects no tissue. A carcinoma of the skin, if allowed to pursue its own course, attacks in succession the subcutaneous connective tissue, muscles, tendons, fascia, periosteum and bone. A carcinoma of the uterus frequently does not destroy life until the rectum and bladder have become involved. A carcinoma of the pylorus in the advanced stage usually involves the liver and pancreas. Local extension of carcinoma may also take place by the growth of the tumor masses in the interior of glandular ducts. In carcinoma of the breast, for instance, a perforation of one of the ducts by the tumor is followed by a speedy obliteration of its lumen by tumor growth which fills the duct somewhat in the same manner as an injection mass which becomes attached to the intact epithelial lining. There is no other tumor or disease that so constantly and to the same extent invades adjacent tissues and organs, and such clinical manifestation is a strong evidence of malignance, and is expressed in

Proposition 8: The progressive extension of a tumor to adjacent tissues and organs, regardless of their anatomical structure, is a strong proof of its carcinomatous character.

Metastasis.—While Proposition 8 refers to one of the constant clinical manifestations of carcinoma, it is of less diagnostic value than the regional and general dissemination of the disease by metastasis, which is observed so constantly during the later stages of carcinoma. As a rule, regional metastasis takes place through the lymphatics; general metastasis through the systemic circulation.

The exhaustive researches of Regaud and Barjon appear to prove that the lymphatic vessels in carcinoma are destroyed, and are not reproduced, which must be regarded as a means of protection against regional and general infection. The large lymphatic channels are often used as pathways for the diffusion of carcinoma, but are seldom infected themselves. The cells from the periphery of the tumor ultimately find their way into the lymphatic channels, and are carried with the lymph stream to lymphatic glands, which serve the purpose of a filter, in which the migrating cells become entangled.

localize and establish an independent center of tumor growth.

Borst has made a very careful study concerning the behavior of the endothelial cells lining the lymph channels when the seat of invasion by carcinoma. He found, 1, endothelial cells in a passive state, without a trace of alteration; or 2, they undergo inflammatory hyperplastic proliferation, and, finally, 3, they take part in the formation of new connective tissue. Even when the endothelial cells gave rise to a colossal proliferation, he could never satisfy himself that they were ever transformed into carcinoma cells, and took no part in the destructive process. On the other hand, they seemed to be in their normal as well as altered conditions antagonistic to the carcinoma cells.

The next proposition is upheld and fully endorsed by all pathologists of the present day.

Proposition 9: Regional metastasis in carcinoma takes place exclusively through the lymphatic channels, and the pre-existing lymphatic structures take no active part in the origin and growth of the secondary tumors.

General Metastasis.—General metastasis may occur by the progressive extension of infection of the lymphatics after the last lymphatic filter has been passed and carcinoma cells find entrance into the general circulation, but such a source of general dissemination is rather the exception than the rule. Usually general metastasis takes place in a more direct manner by extension of the carcinomatous process to veins, and the entrance of carcinoma cells into the general circulation from a tumor thrombus. The researches of Goldman tend to prove that the veins in carcinomatous tumors are involved at an early stage. He stained the specimens by the Unna-Taenger orcein method. Even in the primary tumor he found the veins frequently implicated by the carcinoma tissue perforating the vein walls. The same takes place in the blood vessels of the carcinomatous lymphatic glands, and distant metastatic tumors. The arteries are seldom found involved by carcinoma to the extent of causing more direct general dissemination. The carcinomatous affection of veins appears either, 1, in the form of an obturating tumor thrombus with complete degeneration of the vein wall, or 2, as an intramural extension of the tumor with the symptoms of a proliferating endophlebitis, during which the lumen of the vessel and its wall may be preserved for a long time, or 3, a circumscribed perforation of the carcinoma cells into the vein. During this manner of extension of the tumor to the veins coagulation symptoms of the blood may be entirely wanting.

In all of those events, carcinoma cells reach the venous circulation and either become lodged in the vascular pulmonary filter, giving rise to secondary tumors in the lungs, or they pass through the capillary network of the lungs, enter the arterial current, and become arrested in the capillaries of a distant organ or organs, where they establish independent centers of tumor formation.

Ribbert explains the retrograde transportation of carcinoma cells through the venous system by assuming that the cells which enter the veins soon become surrounded by a layer of the third corpuscle of the blood, and, owing to the great viscidity of the minute embolus, become atached to the inner surface of the vein wall. Without impulse of the heart these minute epimural masses are propelled against the venous current and again become adherent to the intima, an occurrence which is repeated without the heart's action, so that eventually by this method of intravenous transportation wide retrograde dissemination of the disease may take place without obliteration of the lumen of the vessels.

Retrograde extension of carcinoma is of more frequent occurrence through the lymphatics than the veins.

Calzavara describes a very interesting case of this kind. The patient was a woman, 55 years of age, the subject of carcinoma of the body and cervix of the uterus. In the lateral wall of the vagina two hard submucous nodules were found just below the cervix. On removal of the uterus and the two nodules it was found that the uterine tumor presented the typical form of adeno-carcinoma. The submucous vaginal tumors presented an identical structure. In this case the migration of carcinoma cells from the uterine carcinoma through the lymphatics by the retrograde route is clearly shown, as the vaginal mucous membrane was intact. Retrograde extension of carcinoma through the lymphatics is not infrequently seen in advanced cases of carcinoma of the mammary glands after the disease has reached the superficial lymphatics of the skin. Undoubtedly in many of these cases the retrograde extension takes place by carcinomatous thrombo-lymphangitis.

Proposition 10 explains the usual manner in which general metastasis takes place in carcinoma.

Proposition 10: General dissemination of carcinoma usually takes place by direct implication of veins in the primary or secondary tumors. Carcinoma cells reach the venous circulation from an intravenous tumor thrombus, by carcinomatous endophlebitis, or, finally, by perforation of the vein wall by isolated carcinoma cells. Retrograde intravenous extension of carcinoma is due to the transportation against the venous current of minute emboli of carcinoma cells surrounded by a mantle of the third corpuscles of the blood which move step by step upon the intima. Retrograde extension through the lymphatics may take place in the same manner, but there is very little doubt that it is more frequently the result of carcinomatous endolymphangitis.

Is Carcinoma on the Increase?—This question is attracting a great deal of attention at the present time, and is deserving a most careful investigation. Barling, Payne, Jackson and Park are of the opinion that the frequency of carcinoma is rapidly increasing. Statistics appear to sustain this view. From investigations made in Massachusetts with reference to this subject, W. F. Whitney comes to the following conclusions:

"1, the death-rate based upon the total number of deaths and the total population has been made; 2, the rate for each age period (decade) above 30 has been made; 3, the ratio of deaths from cancer to the total number of deaths above 30 and for each age period, also to deaths other than from acute infectious diseases. In whatever way the subject was studied there was found a marked increase in the death-rate from this disease."

Newsholme and Edmund Andrews claim that the alleged increase of carcinoma is more apparent than real. Substantial proof can be advanced for the correctness of this position. More accurate diagnosis, more frequent postmortems, a more general resort to operative interference and increased longevity are some of the more important arguments in proving the relative increase of carcinoma. Carcinoma is a disease of advanced age, hence, with an increase in longevity the number of cases of carcinoma would increase. Andrews has shown by statistics that the average age of persons living in Chicago thirty years ago was 15 years, while at the present time it is 29 years. Before the microscope came into general use as a diagnostic resource many carcinomatous tumors were mistaken for something else, and vice versa. The great advances that have been made in diagnosis have revealed many internal carcinomatous affections that only two or three decades ago would have been overlooked. For these reasons we are warranted in stating in

Proposition 11: The increase of carcinoma as claimed by some recent statistics is more apparent than real.

Etiology.—Very little actual progress has been made during the last five years in the elucidation of the etiology of carcinoma. This subject is receiving at the present time everywhere well-merited attention. In this part of the paper the writer proposes to utilize the more important literature on the parasitic nature of carcinoma *pro* and *contra,* which has accumulated during the last few years. Search for the microbe of carcinoma is a laudable undertaking, but so far it has not yielded any definite reliable results.

PREDISPOSING CAUSES.

Heredity—Every surgeon of large experience has met with numerous cases in which he could trace carcinoma to an hereditary origin. The writer has had cases in which the disease could be traced through several successive generations. The percentage of cases in which carcinoma has been shown to be hereditary is estimated differently by different authors. Paget found a family history of carcinoma in 33 per cent. of the cases collected. Bryant in 12 per cent.

In studying the influence of heredity, it is not fair to exclude from the statistics distant cancerous relatives, as has been done by Cripps, because it is well known that congenital deformities, physiognomy, and mental peculiarities frequently reappear several generations apart, and in distant relatives. There is no reason to doubt that an aptitude for carcinoma is transmitted in a similar manner. What such an heredity predisposition consists of is not known. There are few surgeons, if any, who would not subscribe to

Proposition 12: Heredity is a generally recognized potent predisposing cause of carcinoma.

Age—Advanced age plays an important rôle in the etiology of carcinoma. De La Camp collected 9906 cases of carcinoma with special reference to age as a predisposing cause. Among this number there were only 19 cases less than 20 years of age. Four of these were observed in the new Hamburg hospital. One case was a girl, 19 years old, the subject of a large carcinoma of the ovary. The second case was a large ulcerating carcinoma of the stomach with extensive metastases in a patient 17 years of age. The third, a carcinoma of the pylorus, the size of a walnut, in a boy of 16. The last was a boy, 16 years old, suffering from carcinoma of the rectum with extensive metasases. The writer has seen a carcinoma of the breast in a girl, 21 years of age, a carcinoma of the rectum in a boy 17, and several cases of carcinoma of the stomach in persons between 25 and 30 years of age. These observations tend to prove

Proposition 13: As a rule, carcinoma occurs in persons of advanced age, but occasionally is met with in persons less than twenty-five years of age, and in the latter case the disease is characterized clinically by its great malignancy.

Trauma.—Ziegler has studied the clinical history of 499 tumors in the Munich Clinic, from 1890 to 1895, with special reference to their traumatic origin. This number comprised 328 cases of carcinoma, and 171 of sarcoma. This author found the general assertion corroborated that sarcoma is more likely to follow a single injury; carcinoma, on the other hand, repeated injuries or continuous irritation. In the 328 carcinoma cases the disease developed after a single injury 35 times, and in consequence of prolonged irritation 92 times; in the 171 cases of sarcoma the disease could be attributed to trauma 35 times, chronic irritation 32 times. Löwenthal collected 800 cases in which tumor formation is claimed to have been the result of trauma, and he is inclined to believe as the result of his investigations that trauma has a greater influence in the etiology of tumors than is generally admitted.

Proposition 14: Carcinoma seldom follows a single injury, but develops more frequently in consequence of repeated injuries or prolonged continuous irritation.

Racial, Dietetic, Climatic and Topographical Influences.—It is a well-known fact, confirmed by reliable and extensive statistics, that some races are much more predisposed to carcinoma than others. Diet appears to exercise some influence in the causation of carcinoma. Legrain states that epithelioma is unknown in Algeria, except as it appears in a European. This may possibly be due to an almost exclusive vegetarian diet. Verneuil and Reclus asserted long ago that the herbivora were much less liable to carcinoma than the carnivora; and they ascribe the sixfold increase in the number of patients suffering from carcinoma at their hospital the last forty years to the increased consumption of meat by the laboring classes.

Behla has made a study of the geographical influences in the causation of carcinoma. He states that carcinoma is very rare in the extreme northern and southern countries. The temperate zones of Europe, Asia and America appear to act as a predisposing cause. Carcinoma is very prevalent in Australia, rare in Central Africa, and almost unknown in New Guinea.

Haviland, in his researches, found the disease most frequently along river courses and in localities subjected to periodic inundations, while it is less prevalent in high altitudes and in the spring districts at the head of rivers. It was a noteworthy fact that geologically the alluvial soil appeared to constitute a local predisposing cause, while a chalky or lime soil had the opposite effect. Heimann made similar inquiries, and came to the same conclusions.

Proposition 15: Among the predisposing causes of carcinoma must be enumerated racial, climatic and topographical influences.

Inflammatory Products, Scar Tissue and Benign Tumors.—Carcinoma not infrequently develops in the inflammatory product of tubercular affections of the skin. Desbonnet collected from different sources 86 such cases, and since that time a great many additional cases have been reported.

Goodhart has called especial attention to irritation as a cause of ichthyosis of the tongue and of carcinoma. It has been known for a long time that this superficial chronic inflammation of the tongue frequently precedes carcinoma. In many instances carcinoma of the tongue and of the mucous membrane of the cheek has been traced to prolonged irritation and inflammation caused by displaced carious teeth and to the sharp projecting margins of normal teeth. One of the most instructive illustrations of the influence of prolonged irritation and inflammation in the causation of carcinoma is chronic eczema of the nipple, known as "Paget's disease of the nipple." Another inflammatory product very often the starting-point of carcinoma is the wart. The warts upon the forehead and cheeks of aged persons, "verruca senilis," most frequently undergo such a transformation. The occurrence of carcinoma in an inflammatory product is undoubtedly due to the displacement or penetration of embryonic epithelial cells into the inflammatory product, where they are brought in contact with vascular tissue, which increases their vegetative capacity, and alters their habits of life. A similar histologic cause explains the frequency with which carcinoma develops in scar tissue, where the disease almost without exception begins as a subepidermal nodule from a matrix of embryonic epithelial cells buried in the mesoblastic tissues.

Among the benign tumors which are most prone to become transformed into carcinoma are the papillomata and adenomata. In both of these tumors the essential parenchyma of the tumor, the epithelial cells, are beyond the reach of blood vessels. Any and all influences, local and general, which are capable of stimulating cell growth beyond the physiologic requirements, and growth beyond the physiologic requirements, and which result in penetration of the membrana propia by young epithelial cells, are the causes upon which depends the transition of a benign epithelial tumor into a carcinoma. Among the local causes which bring about such a transformation of a benign into a malignant tumor may be enumerated injury, prolonged or repeated irritation, and incomplete removal of the benign tumor by excision, cauterization and ligation. The above remarks may be summarized in

Proposition 16: Chronic inflammatory products, cicatrices and benign epithelial tumors produce local conditions favorable to the development of carcinoma.

Parasitic Theory of the Etiology of Carcinoma.—The local, regional, and systemic dissemination of carcinoma is strongly suggestive of the existence of some virus or microbe as the essential cause of the origin and spread of carcinoma. In many respects carcinoma resembles several infective processes, the microbic origin of which has been well established. The infectiveness of tuberculosis was recognized a long time before its microbic origin was demonstrated. Pathologists for years have made numerous experiments to prove the inoculability of carcinoma. Hahn, Bergmann, the writer and others have extended their experiments to the human being. In the case of an inoperable carcinoma of the leg, the writer implanted subcutaneously fragments of asceptic carcinoma tissue at two points on the affected limb. A little nodule formed at the point of inoculation during the first two weeks, which gradually disappeared after that time. These nodules represented the product of proliferation of the tissues adjacent to the implanted aseptic foreign substance, in response to the local irritation caused by the carcinomatous graft, which acted the part of a local irritant. The new tissue which formed around the graft was completely removed in the course of two or three weeks by absorption. It is my intention in this part of the paper to utilize the most important literature of the last five years pertaining to the efforts made to prove the parasitic origin of carcinoma, and the material utilized will be divided into two classes, according to the results obtained by experimentation.

Alleged Positive Results.—Among the first to study the parasitic origin of carcinoma upon a scientific basis were Nedopil (1881), Schenerlen, Schill and Frère, Darier, Wickham, Malassez, Albarran, Soudakewitsch, Pfeiffer, Sjöbring, Thoma, Podysoski, Delépine, Ruffer, Stroebe, Steinhaus, O. Israel, Karg, Eberth, Ribbert, Hauser, Hanau, Klebs, Ballance and Shattuck, Kurloff, Ohlmacher and Korotneff. Among the more recent investigators must be mentioned Plimmer, Roncali, Walker, Sawtschenko, J. J. Clark, Foa, Vedeler, Park, Sternberg and many others. The discovery of coccidia in the nuclei of carcinoma by Thoma, in 1889, gave rise to a renewed stimulus to the search of micro-organisms in carcinoma tissue. The parasites found in carcinoma and which have been credited with being the essential cause of the disease are the following:

Schizomycetes 1. (Schenerlen and Koubashoff); histozoons; coccidium of Darier. 2. Coccidium of Albarran. 3. Coccidium of Sjöbring; gregarina moncystidea, or, 4, Rhapalocephalus canceromatosus of Korotneff. 5. Ameba sporidium of Pfeiffer, or sarcolithus of Adamkiewicz. 6. Hematozoon or Kahaur. 7. Histozoon and ameba of Nepvean.

Blastomycetes: 1. Fuchsinophile bodies of Russell. 2. Canceromycet of Niesen. 3. Saccharomyces niger of Maffuci. 4. Blastomycetes of Sanfelice and Roncali.

The parasitic theory takes it for granted that carcinoma is an infectious disease of a chronic type, and is supported to a certain extent by clinical observations; because, if there is a disease, which, by its origin, its rapid development, the frequency of regional and general metastases, the accompanying profound impression on the organism proves to be infectious, it is carcinoma. However, all of the experiments so far made do not answer the requirements laid down by Koch to prove the parasitic origin of this disease.

Positive results from inoculation were obtained by Eiselsberg, Hanau, Francotte and Richter in mice; Firket in rats, Langenbeck, Follin, Lebert and Weber in dogs; Guyon in dogs and cats, and Quinquaud in guinea-pigs; Wehr made 26 experiments with one successful result only; Norinsky had two positive results in 15 experiments.

Hanau inoculated the base of the scrotum of three rats with fragments of carcinoma tissue from a carcinoma of the vulva of a female rat, with positive results. Pfeiffer succeeded in transmitting a carcinoma from one rat to another; Moran from one white mouse to another white mouse; Goujon from one guinea-pig to another, and Klencke from horse to horse.

Auto-inoculations in persons suffering from inoperable carcinoma are four in number. These experiments were made by Hahn, Cornil and the writer with three positive and one negative results (Senn).

Moran, quoted above, succeeded in inoculating a cylindric-celled epithelioma of a white rat through several generations of the same species of animals. Metastasis followed the inoculations. With each generation the transplantation of the neoplasm became more and more difficult, and the malignancy of the tumors produced was gradually diminished. Sanfelice believed that the bodies found in carcinoma cells were blastomycetes, because of their morphologic resemblance. He obtained a pure culture of a blastomyces, "saccharomyces neoformans," from the juice of fruits and cultivated it upon vegetable media. Injection of pure cultures in guinea-pigs produced a sarcoma-like tumor, with glandular involvement, and metastatic foci in the kidney, liver and spleen. The same results were obtained by inoculating mice, while rabbits and dogs proved more refractory. He also succeeded in isolating pure cultures of blastomycetes from human tumors and from tumors of cattle and pigs. The parasite thus isolated, however, did not manifest any pathogenic activity.

Plimmer repeated the experiments of Sanfelice and reached approximately the same results and conclusions. He *found those bodies in 1130 out of 1270 cases of* carcinoma examined. The number of parasites appeared to be proportionate to the malignancy of the tumor. In this respect the results of observation were the reverse of those observed by R. B. Greenough. The latter states: "Furthermore, those cases which showed the most satisfactory specimens of bodies, and of the four cases in which the bodies were most numerous, three were clinically characterized as being of slow growth." The cultivation of this parasite proved most successful under amebic conditions.

Max Schueller has found minute refractile spheres, oval or round, three times the size of a blood corpuscle, with a granular center and a capsule in giant cells of sarcoma and epithelial cells of carcinoma, and believes that these bodies are the cause of malignant tumors, but so far he has not succeeded in reproducing the disease in animals by inoculation. R. B. Greenough, of Boston, who has made a series of careful experiments on the so-called "Plimmer bodies," has reached the following conclusions:

"1. The appearances known as the 'Plimmer bodies' were found in each of 23 cases of breast cancer. 2. They were more numerous in the periphery of the tumors, and in the metastases. 3. They were not found in areas which had undergone even slight degeneration, whether before or after removal. 4. They were more numerous in the slow-growing carcinomata, and less frequently found in the rapidly-growing ones. 5. They were more numerous in scirrhus than in medullary or adeno-carcinoma types of cancer. 6. They were not found in three cases of the epithelioma type (one of which was a typical Paget's disease of the breast). 7. They were present in one case of ovarian carcinoma, and absent in another case of general peritoneal cancer, of probable ovarian origin."

The most recent contribution in support of the parasitic origin of carcinoma is from the New York State Pathological Laboratory, by H. R. Gaylord. The paper appeared in the May number of the *American Journal of Medical Sciences,* and contains much that will interest bacteriologists and pathologists in the near future. He is a firm believer in the protozoon theory of carcinoma. He found these bodies present in all malignant tumors examined in varying number and forms. He followed Plimmer's method of staining, which he considers a great advance in the parasitic study of carcinoma. The form and size of the parasite vary according to age. The mature form possesses ameboid movements. He reproduced the disease in several species of animals by different methods of inoculation. It is too early to accept or reject the deductions he formulates from his own researches. The work done in the important institution of which Dr. Gaylord is director will give a new impulse to the study of the parasitic nature of carcinoma, and within a short time we may expect reports from different laboratories confirming or correcting his conclusions. It is very unfortunate that this contribution first reached the lay press, because the profession for good reasons, regard with suspicion concerning startling discoveries heralded through the general press.

From the evidence produced above, it is not difficult to conceive that the parasitic theory of carcinoma at the present time is based upon inadequate experimental proof. Two great objections present themselves against the validity of the claim that carcinoma is a parasitic disease: 1. The variety of microbes and bodies which have been found in carcinoma tissue by different experimenters, and for all of which, at different times and by different authors, the same specific pathogenic qualities have been claimed. 2. The histologic structure of the products of implantation of carcinoma tissue, or inoculation with the supposed carcinoma germs, does not correspond with the structure of a true carcinoma. This statement applies with special force to the fruit germ of Sanfelice. During the early period of scientific investigation of the cause and nature of tuberculosis, many experimenters produced in different ways local and metastatic pathologic conditions, which resembled in many respects genuine tuberculosis histologically, but lacked the essential microbic cause, and hence was designated as pseudo-tuberculosis. For the same reason, the new tissue produced by the implantation of carcinoma tissue, or inoculation with the so-called carcinoma bodies, might very properly be called pseudo-carcinoma.

In the light of searching criticism, the results of experimentation on the positive side of the parasitic theory of carcinoma can be summed up in

Proposition 17: The positive results of implantation and inoculation experiments have so far failed in establishing beyond all doubt, upon a bacteriologic and histologic basis, the parasitic theory of carcinoma.

Negative Evidence of the Parasitic Origin of Carcinoma.—A vast amount of material has accumulated during the last few years, calculated to combat the claim made by a number of enthusiasts that carcinoma is a microbic contagious disease. The contagiousness of carcinoma is firmly believed by the people, and this opinion is firmly rooted for a long time. A few isolated cases of carcinoma of the penis, attributed to sexual intercourse with women the subject of carcinoma of the uterus, furnish no proof of the contagiousness of carcinoma, as Demarquay collected 134 cases of carcinoma of the penis, and only one of the patients had been exposed to such a source of infection.

No well-authenticated case of inoculation carcinoma has occurred among surgeons who have frequently injured their fingers and hands during operations for carcinoma, while inoculation tuberculosis from the same cause has been frequently observed. The same can be said of persons who take care of carcinoma patients, or who live with them in the same room.

A number of interesting cases of auto-inoculation have been reported by Waldeyer, Klebs, Spiegelberg, Luecke, Kaufmann, Ricard, and Hyvert. At least some of these inoculations are wrongly interpreted, as extension to adjacent parts may have taken place through the lymphatics. Carcinoma epidemics have been described by Arnaudet, Brown, Desplons, Roy, Lucas-Championnière and Marrichon, but these reports have not been confirmed by subsequent and more reliable observations.

Pianese mentions the four cases of inoculation from man to man by Alibert, who experimented upon himself and his students, all with negative results.

On May 4, 1901, the writer inoculated himself with carcinoma tissue immediately after he had completed a radical operation for advanced carcinoma of the lower lip. The patient from whom the malignant graft was obtained was an Irishman 60 years of age. The submental and submaxillary lymphatic glands were involved. The glands were immersed in warm saline solutions and from one of them a fragment the size of a split pea was used for implantation. A small incision was made about the middle of the forearm over the supinator muscles under strict aseptic precautions. One of the margins of the little wound was undermined sufficiently to make a pocket large enough to receive the graft. After implantation the wound was closed with a horse-hair suture and iodoform collodium. The operation was performed by one of my assistants. Dr. Lyman. The carcinomatous nature of the glandular affection was proven by microscopic examination of the gland from which the graft was taken. In the course of a week a nodule the size of a pea made its appearance, which remained stationary for two weeks when it gradually disappeared. At the present time (June 22) a linear red scar indicates the site of implantation.

Inoculations from man to animals, made by Peyvilhe, Schweninger, Klebs, Cazin and Duplay, Valentin, Vogel, Weber, Dubuisson, Hyvert, Chatin, Hénocque, Billroth, Villemin, Cothin, Shattuck, Paulowsky, Fischel, Bogninet, D'Auna and Arcangeli, Pianese and Mayet were all negative. Inoculations from animal to animal were made on an elaborate scale by Paul Bert, Rinne, Doutrelepont Duplay and Cazin, Lablanc, Senn, D'Auna,, Trasbot, Cadiot, Thiroloix, all with negative results.

Sippel implanted fresh carcinoma tissue underneath the dura in 25 rabbits. In not one instance were metastases or lymphatic infiltrations observed.

Peterson and Exner made experiments on guinea-pigs and mice with the saccharomyces neoformans of Sanfelice. They witnessed a general dissemination of this organism throughout the body of the animals experimented upon, but came to the conclusion that this yeast fungus has no connection whatever with the etiology of malignant tumors; and that the cellular inclusions in carcinoma are to be identified only to a limited extent with the fungus, and, finally, that the diseases in man attributed to the saccharomyces have absolutely nothing to do with malignant tumors.

According to Sternberg, Maffuci and Sirleo, the new tissue produced by some blastomycetes when injected into animals can not be regarded as having the histologic structure of carcinoma or sarcoma, but rather as granulomatous productions.

Fabre-Domergue, in his recent work on epithelioma, is outspoken regarding the parasitic origin of carcinoma. He says: "The forms described as sporozoa have merely the morphologic resemblances and not the true characteristics. All the pseudo-coccidia so far pictured are connected by insensible gradations with the tumor cell, from which they emanate by way of degeneration."

Gratia and Lénaux have made inoculation experiments with fresh carcinoma tissue into the lower animals, and uniformly failed to reproduce the disease. Fresh tumor tissue was ingrafted into the skin, the peritoneal cavity, and the walls of the stomach. Fresh carcinoma juice was injected into the organs most frequently the seat of the disease. They did not succeed in transmitting the disease from human to dog, or from dog to dog, and consequently conclude that contagiousness direct or indirect has not been present; that the parasitic origin is yet a matter of doubt; that the course and pathogenesis are still undecided.

Kurscherf and Bartsch repeated the experiments of Adamkiewicz on carcinoma implantation. They ascertained that if careful aseptic precautions were employed, the grafts degenerated and were absorbed.

Suspecting that the soil had something to do with the prevalence of carcinoma, Ruver obtained soil from parts of England where carcinoma is prevalent to a high extent, mixed it with the pulpified carcinoma tissue and placed rats upon it so that the feet and tail were constantly in contact with the mixture. The animals were also exposed to the spray of carcinoma tissue, and the accessible mucous membranes were kept in a state of irritation, and yet, in spite of all those potent etiologic agencies, the disease could not be reproduced in the animals thus experimented upon.

Sternberg has arrived at the conclusion that, while the investigations into the parasitic origin of malignant tumors have given rise to a more careful study of the cells, they have not advanced our knowledge of the etiology of tumors a single step. MacFarland, from his own observations, and studies comes to the conclusion that carcinoma is not a specific disease, that its etiology may be said to be dependent upon the inherent proliferative tendency of the epithelium; that is, it is epitheliogenetic, not parasitic.

Curtis has been experimenting five years with the saccharomyces tumefaciens. In that time he has never been able to produce a real tumor, compared to those observed in the human subject. The lesions produced were always the same; either a local growth of the fungus, sometimes of large size, or an inflammatory product with leucocytosis and more or less connective tissue proliferation—a granuloma. He makes the assertion that in non-ulcerating carcinoma he has never seen a single blastomyces.

Duplay and Cazin decide from their own observations that it is improbable that malignant growths are transmissible, either by graft or inoculation, from animals of one species to those of another.

Steinhaus has well said recently: "It is time to take up again the investigations on carcinoma, without neglecting the scientific method, as the principal cause of the errors committed so far is due to the neglect of the scientific method."

Peterson regards Darier's psorosperms to be forms of degeneration of the epithelial cells. He obtained his best pictures by staining with pictrocarmin and hematoxylin. The latter was used in weak solution and the preparations were overstained. They were then removed for from one-half to two minutes to a solution of the ferric sulphate oxydatum, and then decolorized in HCl—alcohol.

The painstaking researches of Pianese, of Naples, seem to prove that all carcinoma parasites so far discovered and described are the products of cell alterations.

Schwarz made a critical study of 40 cases of carcinoma in reference to the parasitic origin of the disease, and came to the conclusion that the "carcinoma parasites" which have been described under different names are either leucocytes or the products of cell degeneration and abnormalities of nuclear segmentation

He discusses at length and in a logical manner the intracellular and extracellular cell inclusions.

Lubarsh, in his recent classical treatise ("Zur Lehre von den Geschwülsten u. Infektionskrankheiten," Weisbaden, 1899), studied the blastomycetic theory of Sanfelice, Roncali, etc., experimentally, and obtained only negative results.

All inoculations with Sanfelice's original cultures without exception yielded negative results. The experimental work of E. H. Nichols, of Boston, in search for the parasite of carcinoma, its cultivation and attempts to reproduce the disease artificially in animals, is summed up by him as follows:

"Typical cancer bodies have been found generally present in certain types of cancer. They never have been found in epidermoidal cancer. Attempts to produce cancer in animals by inoculating them with bits of tissue from human cancer so far have uniformly failed. No attempt to isolate an organism from human cancer has succeeded. Inoculation of animals with the organisms of Sanfelice and Plimmer has resulted in the formation of nodules composed of proliferated connective tissue cells and newly formed blood vessels (granulation tissue), but no tumor resembling cancer of human beings has been produced."

Professor Adami, in his recent instructive article on carcinoma, says: "In other words, so far as our present knowledge permits us to conclude, bacteria—schizomycetes—below a certain degree of toxicity of their products, can not maintain an existence in the tissues of animals. They succumb to the anti-bacterial mechanisms of the organism, and, succumbing, any proliferative activity they may have induced comes to an end. In plants, it is true, we meet with definite bacteria living a symbiotic existence in the rootlets and causing well-marked overgrowths. It may be eventually found that bacteria are capable of initiating progressive cell growth in the higher animals, but of this power proof is so far wanting." Again: "Continuous purposeless growth is characteristic of all forms of tumors proper; nevertheless, as I have already stated, in a very large group of tumors all the evidence we possess points surely to the fact that microbes have not initiated the growth, and are not concerned in the continuance of the growth." The evidence introduced to prove the non-parasitic side of carcinoma overbalances by far the testimony furnished on the positive side, both as far as the number of investigators is concerned, and the logical deductions drawn from their work. We are, therefore, warranted in stating in

PROPOSITION 18: A careful study of the experimental researches and bacteriologic and histologic investigations concerning the etiology of carcinoma does not at the present time warrant us to claim for this disease a parasitic origin.

TREATMENT.

As we are still ignorant concerning the essential etiology and true nature of carcinoma, the treatment pursued up to the present time has been largely of a palliative, tentative and empirical nature. The only real advances made have been in its operative treatment. It is true, from time to time remedies have been proposed for which specific curative properties were claimed.

Internal Medication.—Arsenic, condurango, turpentine, chelidonium, and many other drugs administered internally have all had their advocates, but none of them on extensive trial have shown any decided, to say nothing of specific, curative effect in retarding or arresting the growth of carcinoma.

During one of the meetings of the American Medical Association, Washington Atlee extolled the therapeutic virtues of arsenic in the treatment of carcinoma, more especially after operation, with a view of preventing a recurrence. He insisted that this drug should be invariably administered, and that its use should be enforced, even if the stomach would tolerate only a fraction of a drop of Fowler's solution. Since that time the writer has always followed out his directions, but after an extensive experience he is not prepared to assign to it any curative properties whatever. Jonathan Hutchinson is of the opinion that the use of arsenic rather favors than retards the evolution of carcinoma.

Denissenko claims to have obtained more benefit from the internal use and subcutaneous injections of chelidonium majus. The injections were not made into the tumor, but into the tissues surrounding it, where the injected irritating substance initiates a sclerosis like other sclerogenic agencies. The injections used were composed of half a gram of the extract and the same quantity of water, properly sterilized by boiling, and injected every two to five days.

Berezkin gave this remedy a faithful trial in nine cases by internal administration and hypodermic use, and failed to observe the slightest curative effect.

J. Carne Ross asserts that the internal use of large doses of cinnamon mitigates the pain and retards the growth of carcinoma.

Mr. Snow advocates very strongly the use of opium as soon as it has been ascertained that the disease is beyond the reach of a radical operation.

PROPOSITION 19: The experience of centuries and the internal use of innumerable remedies have demonstrated that so far carcinoma has not been materially influenced for the better by this method of treatment.

Parenchymatous Injections.—Direct medication of the carcinoma tissue by parenchymatous injections has had an extended but unsatisfactory trial. Acetic acid, nitrate of silver, and the different antiseptics have all failed in making a curative impression on the evolution of the disease; in fact, in most instances tumor growth was favored by such attempts. Schwalbe many years ago advocated the injection of alcohol into the loose connective tissue around the periphery of the tumor, and reported a number of cases in which this treatment appeared to have been useful in retarding if not arresting further growth of the tumor. The stimulating effect of this powerful antiseptic on the connective tissue resulted in sclerosis and diminished the blood supply to the tumor. The writer has given this treatment an extensive trial, and believes it is the least objectionable and most useful form of treatment by parenchymatous medication. He has used Lannelongue's sclerogenic chlorid of zinc solutions with similar results. The experience with parenchymatous injections up to the present time is voiced in

PROPOSITION 20: Direct medication of carcinoma tissue by parenchymatous injections has no influence in retarding or arresting the growth of carcinoma, while the injection of sclerogenic substances into the connective tissue around the border of the tumor appear to restrain the local extension of the disease by impairing the blood supply to the parenchyma of the tumor.

Local Applications.—Upon the very highest authority methyl-blue was recommended a few years ago as a local remedy in the treatment of carcinoma. The ease with which this staining material permeates the protoplasm of cells was considered a strong argument in favor of its therapeutic value. Accumulated experience, on the whole, with the use of this agent has been disappointing. Darier has seen good effects from the local application of a 20 per cent. solution to open, ulcerating carcinoma. He advocates strongly as a palliative measure the conversion of an open into a closed carcinoma by a plastic operation about the fifteenth or twentieth day after treatment with methyl-blue.

W. Mitchell recommends the local use of formalin in the treatment of certain inoperable malignant tumors. He uses a 20 per cent. solution. The dry eschar produced by the formalin is removed after a few days, when the formalin is again applied, and this procedure is repeated until the tumor is removed. The applications occasion a great deal of pain, and are followed by considerable edema of the surrounding tissues. Very little is to be expected from local applications in the treatment of ulcerating carcinoma; hence it is safe to assert in

PROPOSITION 21: Local applications of any kind in the treatment of ulcerating carcinoma must be considered at best only in the light of palliative measures.

Cauterization.—Among the earliest attempts to destroy carcinoma were the red-hot iron and chemical caustics. This method of treatment has its advocates to-day.

Czerny and Truneck have found a solution of arsenic in equal parts of alcohol and water, 1 to 75, of much value in the treatment of ulcerating non-operable epithelioma. The ulcerated surface is thoroughly cleansed and brushed daily with the solution, and the eschar is gradually thickened. With the increase in the thickness of the eschar a stronger solution is applied. Pain is caused only in the beginning of the treatment. Finally, the eschar becomes detached and the epithelioma is destroyed. Three cases of extensive epithelioma of the nose in aged persons are reported as cured. This treatment was given a thorough trial in four cases of epithelioma of the skin in Bruns' clinic, and Honsell, who made the report, states distinctly that in all of them the result was negative. The arsenical application did not affect the carcinoma tissue to any extent. It is safe to affirm in.

PROPOSITION 22: The actual cautery and chemical caustics have only a limited field of usefulness in the treatment of open inoperable carcinoma. They should never be employed in the treatment of closed carcinoma, as a substitute for the knife.

Serum Treatment.—If carcinoma is a microbic disease, the search for a healing serum must be regarded as the most logical attempt to find an effective cure. So far all efforts in this direction from Adamkiewicz carcinoma serum to Coley's fluid have proved utter failures. Coley himself does not claim much for his toxins in the treatment of carcinoma. The report on Coley's treatment, made in 1896 by Stimson, Gerster and Curtis, to the New York Surgical Society, represents the experiences and opinions of nearly every surgeon who has given the treatment an extended trial. "1. The danger of the treatment is very great. 2. The alleged successes are few and doubtful in character, and the most that can be fairly claimed for the treatment by toxins is that it may offer a slight chance of amelioration. 3. Valuable time is often lost in operable cases by pursuing the treatment. 4. The method should never be resorted to except in absolutely inoperable cases."

The writer has given this treatment a long and faithful trial in a very large number of operable cases, and has never witnessed the slightest improvement; on the other hand, it generally aggravated the local conditions and hastened the fatal termination.

Peterson made a careful study of the literature of the bacterial treatment of malignant disease, more especially of the cases treated in Czerny's clinic, and came to the conclusion that the treatment is not of the slightest use in carcinoma; that in very exceptional cases sarcoma disappears under its influence; and that the treatment itself possesses many elements of danger.

The employment of blood serum obtained from animals, goats, dogs, asses and sheep, treated by injecting carcinoma juice until the animals no longer responded, has also yielded only negative results. Six years ago this method of treatment was highly extolled by Emmerich and Scholl, and Richert-Héricourt and a number of other French surgeons. The latter reported fifty cases treated by this serum, and claimed to have observed marked improvement in the symptoms under its influence. Bruns treated five cases of carcinoma, and one of malignant lymphoma, by this method. In not a single case did the injections prove of the slightest benefit in diminishing the size of the tumor.

Rydygier made use of the Emmerich-Scholl carcinoma serum in three cases of inoperable carcinoma. Not the slightest curative effect was observed in any of them. The negative results following the different methods of serum treatment heretofore employed would speak rather against than in favor of the parasitic nature of carcinoma.

PROPOSITION 23: The treatment of carcinoma by different sera has without any exceptions yielded only negative results.

Operative Treatment.—The operative treatment of carcinoma has undergone a decided improvement during the last decade. A better knowledge of the manner of local and regional extension of the disease has resulted in a more effective and radical technique in operations upon different organs and regions of the body. The more radical procedures are the outcome of the laborious and accurate researches of Heidenhain, who showed the way to surgeons in following the disease along the pathways of local and regional extension. He emphasized the importance of early and thorough operations. He was one of the first who, upon a scientific and anatomic basis, urged surgeons to perform more radical operations, by following the regional lymphatic channels and glands and remove them with the organ primarily affected. He insisted that local recurrences are seldom the result of traumatic inoculation, but follow in consequence of imperfect removal of the regional metastases. Every surgeon now recognizes the importance of early and radical operations. In this country Halsted was the first one who fully appreciated the teachings of Heidenhain, and accepted and applied in his practice his suggestions. In his last paper on the operative treatment of carcinoma of the breast he makes his operations more radical of late. He almost invariably removes both pectoral muscles and clears out the supraclavicular space, and says in defense of this procedure that in 34 per cent. of cases of mammary carcinoma it will be found that the disease has extended to this region. He does not consider it necessary to divide the clavicle preliminary to this step of the operation. He begins the dissection at the junction of the internal jugular and subclavian veins, and this point is exposed by a vertical incision along the posterior border of the sterno-cleido-mastoid muscle. He now removes both pectoral muscles, and thinks it probable that he will come to remove the contents of the anterior mediastinum. Of 76 patients operated upon over three years ago, 31 are now living without evidence of local recurrence of metastasis. Of 10 patients who died, more than three years after the operation, only one showed local recurrence. Thus, over 52 per cent. of his patients lived more than three years without either local recurrence or metastasis. This is certainly an enviable record, which it would be found difficult, if not impossible, to duplicate, and furnishes the strongest argument in favor of the most radical treatment.

Sanderson and others approve of the clearing-out of the supraclavicular space when the apex of the axilla is extensively involved, or when the supraclavicular glands are enlarged.

A. Lane advises section of the clavicle as a preliminary to clearing-out the triangle, but, as a rule, this can be done without dividing the bone. In very extensive disease of the axilla, supraclavicular space and Mohrenheim's fossa, the same author advocates amputation at the shoulder joint. He argues that in such cases the loss of the arm would in any case result from the dissemination of the disease, and death would soon follow, consequently we are justified in sacrificing the arm, because we may obtain full recovery with merely the loss of the arm. The same heroic treatment under similar conditions was recommended by Theodore McGraw in 1878, but it is doubtful if the suggestion from either of these sources will ever become an accepted practice. The same radical procedures which are now so generally practiced in the removal of a carcinomatous breast are being applied with the same thoroughness in the removal of other organs. Thus, in carcinoma of the lip, it is not generally conceded that the submental and submaxillary glands should be removed with the adipose and connective tissue in one connected piece at the same time.

As one of the modern curiosities in the modern operative treatment of carcinoma must be mentioned the suggestion first made by Beatson, to perform oöphorectomy for carcinoma of the breast. Cases have been reported by Beatson, G. E. Herman, Stanley Boyd, Watson Cheyne, and others. The results were usually only temporary, if any. Cheyne believes the operation might prove of value in young subjects. The curative effect of this operation is attributed by its advocates to the occurrence of atrophy of the gland, and fatty degeneration of its parenchyma, which conditions are established after the normal menopause, and hence would follow the anticipated menopause by the removal of the ovaries. This freak of modern surgery will not find any new advocates. The modern operative treatment of carcinoma is summed up in

Proposition 24: The early and radical operative treatment in carcinoma offers the only prospect in permanently eliminating the disease.

Contra-indications to Operative Treatment.—The operative treatment of carcinoma has at the present time its well-defined limits. Many lives are lost prematurely and much additional suffering induced by indiscriminate operations for malignant disease. A radical operation is only indicated if, from the extent of the disease and the physiologic importance of the organ primarily involved, all diseased tissue can be removed without any immediate or remote danger to life. An incomplete operation invariably aggravates the local conditions and shortens life. An incalculable amount of harm has been inflicted by ignoring the importance of contra-indications to radical attempts, and many patients have succumbed prematurely to such indiscreet attempts. The surgeon has no right to cut life short by such interference simply because the patient is suffering from an incurable disease. If the general and local conditions of the patient are such as to preclude the possibility of obtaining a result warranting a radical attempt, the surgeon must be content to limit his functions to palliation and should never ignore, from a moral and professional standpoint, the significance of the time-honored adage, *nil nocere*.

Time of Recurrence.—Carcinoma statistics showing the permanency of the curative results of operative treatment are very misleading. The three-year limit is still regarded as a standard, which is certainly a great mistake. The writer has seen in a number of his cases recurrence at the site of operation six and seven years after operation, in consequence of which he has become fully convinced of what is stated in

Proposition 25: The permanency of the results of the operative treatment of carcinoma can not be determined in less than ten years after the operation.

Proposition 26: A radical operation for carcinoma should never be attempted unless the local conditions and general health of the patient are such as to promise an equivalent of the immediate and remote risks to life and comfort involved by the operation.

Suggestions.—If carcinoma is, as we have every reason to believe at the present time, the produce of an erratic cell proliferation beyond the limits of the influences which preside over and regulate normal tissue growth, it appears rational to search for some remedy which would affect the parenchyma of the tumor in one of two ways: 1. An agent or agencies which would destroy the epithelial cells by causing speedy and early degeneration of the imperfectly developed epithelial cells. 2. The employment of a local or general remedy or remedies possessing the power of converting embryonic into mature epithelial cells. Ligation of the principal arteries supplying the tumor tissue with blood, and the employment of sclerogenic substances have been employed for the purpose of accomplishing the first object, but so far only with indifferent results. Very little, if anything, has been accomplished in the conversion of the low type of epithelial tissue into mature tissue, that is, in transforming a carcinoma into a benign epithelioma. It is, however, not beyond the range of possibilities that future experiments and observations will open up a wide field of usefulness by the discovery of such agencies that will exert a beneficial or curative effect on the essential tumor elements by inciting degenerative processes, or by converting them into tissue of a higher, mature type; remarks which lead us to frame

Proposition 27: Taking it for granted that carcinoma is the product of an erratic, planless cell growth outside of the range of the physiologic influences which preside over and regulate normal growth and tissue repair, it appears logical in the search for curative agencies to make experiments and observations with the view of finding a remedy which would destroy the tumor by causing an early and speedy degeneration of its parenchyma, or which would possess the property of converting embryonic into mature epithelial cells, thus converting a carcinoma into a benign epithelioma.

CIRRHOSIS WITH PIGMENTATION.[*]

THOMAS B. FUTCHER, M.B. (TOR.)
Associate in Medicine, Johns Hopkins University; Resident Physician, Johns Hopkins Hospital.
BALTIMORE, MD.

The cases of cirrhosis of the liver with pigmentation of the skin or tissues, or of both together, constitute a small but most interesting group. There has been a great deal of speculation as to the etiology of these cases. The purpose of this paper is to present as briefly as possible the history of this form of cirrhosis, the clinical symptoms and pathology of the disease and the present views entertained concerning its etiology.

HISTORY.

Pigmentation of the skin and tissues, other than that resulting from the staining with the bile, does not occur in association with the atrophic cirrhosis of Laennec. In 49 cases of this type of cirrhosis that have been treated in the medical wards of the Johns Hopkins Hospital up to the present date, no single instance of permanent pigmentation has been observed. Of 8 cases of hypertrophic cirrhosis of the liver 1 presented a remarkable grade of bronzing of the skin. Reference may be made here to the fact that a considerable percentage of a consecutive series of livers at autopsy have been shown to contain iron-holding pigment in the liver cells and connective tissue. Thus, Lindemann[1] examined 25 livers, which practically showed no pathologic change, and found a deposition of iron-containing pigment in about two-thirds of them. Kretz,[2] on the other hand, in the examination of a much larger series, found hemosiderin in only 5 to 6 per cent. of the livers.

The forms of cirrhosis with pigmentation have been studied chiefly by German and French physicians. Previous to two years ago, when Opie[3] reported a case, there was practically no literature on the subject in English, with the exception of a brief reference to a case by Adami.[4] in 1898. The most comprehensive review of the subject has been made by Anschütz.[5]

The French physicians were the first to draw attention to the pigmentation of the skin in association with cirrhosis of the liver. In 1882, Hanot and Chauffard[6] described 2 cases of diabetes mellitus associated with hypertrophic cirrhosis of the liver and bronze-like pigmentation of the skin. The autopsy on the first case showed cirrhosis of the liver, characterized by wide bands of connective tissue. The liver cells, as well as the interlobular connective tissue, contained brown pigment granules in great quantities. The second case, which was more carefully studied, showed definite brown pigmentation of the pancreas and liver, both of which were the seat of advanced chronic interstitial inflammation, the parenchyma and connective tissue both containing masses of pigment. The stomach and duodenum were of a bluish-black color and pigment in small granules was found beneath the serosa. Four years later, Letulle reported two similar cases. In 1886, Hanot, in association with Schachmann, published a fifth case. He believed that the knowledge acquired from the study of these five cases established the existence of a new form of cirrhosis, *cirrhose pigmentaire diabètique*, and of a new clinical condition, *diabète bronzé.*

CLINICAL SYMPTOMS.

The clinical symptoms of the condition known as *diabète bronzé* are quite similar in all cases. Anschütz analyzed twenty-four cases which he had found in the literature up to 1899. The picture is one of rapidly fatal diabetes mellitus, associated with cirrhosis of the liver, usually of the hypertrophic variety. The diabetic symptoms have manifested themselves in the majority of cases within one year previous to death. Pigmentation of the skin is usually present but not constant. All the 24 cases were in males; Letulle has stated that of 30 known cases all were in men. The cases have all occurred between 30 and 60 years of age and the majority have been in the fourth and fifth decades. It has been thought that the disease is more common in France than elsewhere and the fact that 17 of the 24 cases occurred in that country would seem to support this belief. This frequency may, however, be due to the French physicians being more familiar with the condition and less likely to overlook its occurrence.

PATHOLOGY.

At autopsy the liver presents the features of a pigmentary cirrhosis. This was the type in 23 of the 24 cases. The liver was enlarged in all the cases but one. An ochre-colored pigment containing iron was present in the liver cells and connective tissue of all the cases. In 2 cases no statement was made concerning the condition of the pancreas. Of the remaining 22, all showed gross changes excepting one. In the 18 cases in which a microscopic examination was made, pigmentation of the glandular epithelium and connective tissue was present, and in 15 of the cases there was marked increase in the amount of connective tissue. The ochre-colored pigment is also present in the muscle fibers of the heart and in the lymphatic glands. The frequency of the occurrence of sclerosis of the pancreas is of importance from the standpoint of the etiology of the diabetes.

ETIOLOGY.

There has been much speculation regarding the pathogenesis of these cases of *diabète bronzé*. Hanot, Chauffard and Schachmann have held that the primary etiologic factor is the diabetes mellitus. They believe that the diabetic alteration of the blood, in association with endarteritis, which has been constant in their cases, causes a nutritional disturbance of the liver cells, with a consequent alteration of the pigment metabolism and a deposition of pigment within the cell-body. They further believe that the pigment thus formed is reabsorbed by the capillaries, and diffused possibly in the form of emboli over the entire organism. As the same form of pigment deposition takes place in other organs —e. g., the heart—as that which takes place in the liver, Letulle came to the conclusion that the pigment is formed in the cells of the various organs in which it is found, from the hemoglobin of the blood. He also holds that the diabetes is primary and thinks that the disintegration of the hemoglobin occurs under the influence of the hyperglycemia. Brault and Galliard, Hernandez, Mossé and others also consider the diabetes the primary and essential cause of the pigmentation.

Another smaller group of observers hold that the pigmentation is produced by a primary disease of the blood and that as a result of some fundamental cause there is an alteration of the blood and subsequent formation of pigment from the altered hemoglobin. An explanation must then be sought for the associated diabetes and cirrhosis of the liver. Marie holds that as a result of some primitive cause, there follows a dissolution of the hemoglobin, which is transformed by the protoplasm of the various body cells into pigment, which is deposited in them. This pigment in turn causes a degeneration and destruction of the containing cells and consequently a chronic interstitial inflammation of various organs, particularly the liver. He believes that bronzed diabetes is neither clinically nor pathologically the classic diabetes, but a distinct morbid entity. Acard, Dutournier, and Jeanselme support Marie's theory, and suggest that the diabetes is possibly only an accessory phenomenon which appears alone when the chronic interstitial pancreatitis reaches a certain grade.

[*] Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee of the Section: Drs. Frank Billings, George Dock and J. M. Anders.

In 1889 von Recklinghausen[7] described, under the name of "hemochromatosis," a condition of pigmentation affecting various organs. This pigmentation, he states, may be either local or general. Brown pigment, which he thinks is derived from the hemoglobin of the blood, is deposited within certain tissues and gives to them macroscopic pigmentation. Quincke, in 1877, had already described a case of diffuse pigmentation in anemia, and Tillmanns observed a case of pigmentation of the liver and lymph glands following trauma. Further, Hindenlang had described a pigmentary infiltration of the lymph glands, liver and other organs in a case of morbus maculosus Werlhofii.

The anatomical features of von Recklinghausen's hemochromatosis cases are striking. The majority of the glands of the body have a deep brown color and their secreting cells contain reddish-yellow or ochre-colored granules. The liver is usually enlarged and often enormously so, the enlargement frequently involving the left lobe to a greater extent than the right. The ochre-colored granules are contained in the parenchyma cells and in Kupffer's cells, and their presence gives the organ a brownish, slaty appearance. The pancreas is usually enlarged and shows chronic interstitial disease. The pigment has the same distribution and appearance as in the cases of diabète bronzé already described. The spleen is often very much enlarged, firm and pigmented. The skin, when pigmented, shows a deposition of pigment in the cells of the sweat glands. This pigment, so far considered, has been shown to be an iron-containing pigment. A second kind of pigment, differing from the first by its occurrence in finer granules of a pure yellow color, is found in the smooth muscle cells of the stomach and intestines, of the blood and lymph vessels and rarely in those of the urinary bladder and vas deferens. It also occurs in the connective tissue of certain localities, for example, Glisson's capsule, the splenic trabeculæ and the sheaths of blood vessels. This yellow pigment does not give the reaction characteristic of iron. Von Recklinghausen called the iron-containing pigment "hemosiderin," the iron-free pigment "hemofuchsin." He thinks that both of these pigments are derived from the hemoglobin.

Von Recklinghausen described 12 cases which he considered examples of local and general hemochromatosis. He defines hemochromatosis as a condition of pathologic pigmentation due to the deposition of pigment derived from the blood. There is a form of localized pigmentation of the intestine, caused by the deposition of fine yellow granules in the smooth muscle cells. Such cases have been described by Goebel and Hintze and must not be confused with true hemochromatosis. This pigment does not contain iron, whereas in hemochromatosis the iron-containing pigment is the most striking and characteristic feature of the disease.

Opie states that the important features of hemochromatosis are: 1. The presence in the epithelial cells of various glands, notably the liver and pancreas, of an iron-containing pigment. 2. The presence of an iron-free pigment in smooth muscle cells of the gastro-intestinal tract and of the blood vessels and lymph vessels and in certain connective tissue cells. 3. The association of cirrhosis of the liver with the pigmentation. He says that to this condition, which is apparently a distinct pathologic entity, the term hemochromatosis should be limited, even though von Recklinghausen, its originator, applied it to conditions of local pigmentation as well.

In this disease the questions which are of most interest to us are: 1, the cirrhosis of the liver and its etiology; 2, its relation to the diabète bronzé of the French. Without going into detail, it may be stated that the deposition of the pigment in the liver is now universally regarded as the exciting cause of the liver changes. This deposition leads to a degeneration and destruction of the liver cells with the eventual setting up of an interstitial hepatitis.

The relation of hemochromatosis to diabète bronzé is very close and the general opinion of the most recent observers is in favor of their being identical. According to this view, the cirrhosis is merely a question of the duration of the disease. A considerable percentage of the reported cases of hemochromatosis have developed diabetes in the late stages of the disease, at once suggesting an analogy between the two conditions. Diabetes was present in 1 of von Recklinghausen's 12 cases. It will be remembered that a small group of French writers regard the diabetes the result rather than the cause of the disease, and that the essential etiologic factor is a primary disease of the blood. This group of observers hold that the diabetes only occurs when the chronic interstitial pancreatitis, resulting from the pigment deposition, reaches a certain grade. Those who have published cases of hemochromatosis with diabetic symptoms ascribe the latter to the same cause.

Buss and Opie have reported cases which seem to bridge over the gap between the two conditions. The former reported a case of diabetes associated with cirrhosis of the liver and of the pancreas and with general hemochromatosis. He found the iron-containing and the iron-free pigment in locations corresponding with those mentioned by von Recklinghausen. There is no reason to doubt that in this case the pigmentation was identical with that of hemochromatosis, while it also presents the clinical and pathologic picture to which Hanot gave the name diabète bronzé. In Opie's case, associated with hemochromatosis, there was bronzing of the skin, cirrhosis of the liver of advanced grade, and chronic interstitial pancreatitis, but diabetes was not present. Opie states, "It is evident, then, that the generalized pigmentation of bronzed diabetes is the hemochromatosis of von Recklinghausen." It will be of great interest if the pancreas in those cases associated with diabetes will be found to show the hyaline degeneration and sclerosis of the islands of Langerhans which Opie[9] has recently demonstrated in chronic interstitial pancreatitis with glycosuria and in a case of ordinary diabetes.

While Opie and others regard hemochromatosis as a distinct morbid entity, Adami and Dr. Maude Abbott[10] are not fully convinced that it is a distinct and separate disease.

Whatever the final decision as to the relationship between hemochromatosis and diabète bronzé many turn out to be, it is sufficient to say that practically all cases of cirrhosis of the liver with diffuse pigmentation of the tissues conform to one or the other of these two conditions. The cirrhosis found with pigmentation is practically always of the hypertrophic type. The liver is always firm, easily palpable and frequently the enlargement seems to involve the left lobe to a greater degree than the right. There is usually a firm, enlarged, palpable spleen associated with the cirrhosis.

Our present knowledge concerning hemochromatosis may be best stated by quoting the conclusions of Opie, which were drawn two years ago:

"1. There exists a distinct morbid entity, hemochromatosis, characterized by the widespread deposition of an iron-containing pigment in certain cells, and an associated formation of iron-free pigments in a variety of localities in which pigment is found in moderate amount under physiologic conditions.

"2. With the pigment accumulation there is degeneration and death of the containing cells and consequent interstitial inflammation, notably of the liver and pancreas, which become the seat of inflammatory changes accompanied by hypertrophy of the organ.

"3. When chronic interstitial pancreatitis has reached a certain grade of intensity, diabetes ensues and is the terminal event in the disease."

So far as I am aware, only four cases of cirrhosis of the liver with general pigmentation, or, in other words, hemochromatosis, have been reported from this country. The first was Opie's case, reported before the meeting of the Association of American Physicians in May, 1899. At the same meeting Adami, in discussion, spoke of a case to which he had referred in an article in the "Annual and Cyclopedia of Practical Medicine" for 1898, and which was later, in 1900, reported in full by Dr. Maude E. Abbott. The other two cases were reported by Osler,[11] in 1899.

Dr. Abbott's case is of especial interest, in that it is the first case of hemochromatosis that has been reported in a female. It is also of interest that none of the American cases have had glycosuria.

I shall refer briefly to Case 1 reported by Osler, as I have frequently seen the patient personally and he is still under observation. The patient is now 50 years of age and a pilot by occupation. There is nothing in his family or personal history of direct bearing on his present illness. He had used alcohol very moderately. Five years previous to the present date he had his first attack of purpura over the feet. Since that date he has had scores of these outbreaks of red blotches over the feet and legs, and recently the purpura has extended to involve the thighs. There was some swelling of the feet associated with some of these attacks. In February and October, 1897, he had severe attacks of pain between the right costal margin and iliac crest. For some time before he entered the Johns Hopkins Hospital, on May 1, 1899, the patient's friends had noticed that his face had become much darker in color and the patient himself observed that his hands were becoming darker. On examination, in May, 1899, he was a sparely built, healthy-looking man. The skin of his face was slightly bronzed. The general surface of the skin was moderately pigmented. The areolæ of the nipples and the genitalia were very much pigmented. The skin of the hands and wrists, and of the legs as high as the knees was very deeply bronzed. The liver was markedly enlarged; the edge could be distinctly felt in the median line 8 cm. below the ensiform cartilage and between 6 and 7 cm. below costal margin in the mammillary line. The surface was everywhere smooth and it was hard, firm and rounded. There was an audible friction rub over the liver on deep inspiration. The spleen was enormously enlarged, was distinctly visible and its border was palpable 6 cm. from the costal margin. The urine contained no albumin. Indican was present. The reaction for iron was also present. No sugar was found on repeated examination. Seventy-five grams of glucose were given on an empty stomach without sugar appearing in the urine. A portion of the skin of the leg was excised and Opie found the characteristic iron-containing, ochre-colored pigment granules in the cells of the sweat glands, practically demonstrating the fact that the case is one of hemochromatosis.

The patient has repeatedly returned for observation, and was examined by Dr. Osler on May 30, 1901. The same general features are still present. The bronzing of the skin had become intensified. The liver and spleen were enormously enlarged and he then had a purpuric eruption over the legs. He had been quite ill for one month and was decidedly weaker and thinner. The urine was still free from sugar. It would thus seem that if he has changes in the pancreas, of which there is little doubt, they are not sufficiently advanced to produce diabetes.

This case illustrates the long duration of the disease, which is so common in these cases. The recurring hemorrhages are of interest. This is a common symptom of the true hypertrophic cirrhosis of Hanot. Evidences of a hemorrhagic diathesis have been noted in 5 of the 24 cases of diabète bronzé collected by Anschütz. In 3 cases a moderate grade of purpura had been noted. In 1 case hematuria occurred and in 1 repeated attacks of epistaxis.

CIRCULATORY DISTURBANCES ACCOMPANYING HEPATIC CIRRHOSIS

AND INOSCULATION OF THE PORTAL BRANCHES WITH THE SYSTEMIC VEINS.[*]

CHARLES G. STOCKTON, M.D.
Professor of the Principles and Practice of Medicine and Clinical Medicine, University of Buffalo; Attending Physician, Buffalo General Hospital.
BUFFALO, N. Y.

In typical atrophic cirrhosis of the liver—the cirrhosis of Laennec—the most striking clinical features are those related to the disturbances in circulation. The obstructed portal radicals and consequent distension of the portal vein, the raising of the blood pressure in the portal vessels, the resulting congestion of the abdominal viscera, and the development of ascites are familiar manifestations. In a paper, read before this Section at the Newport meeting, in 1889, I ventured to express some views connected with this subject, which did not meet with the approval they seemed to me to deserve, and I, therefore, purpose reviving these views on this occasion.

---

RELATION OF PORTAL TO GENERAL CIRCULATION.

When one considers the anatomy and physiology of the portal system of veins, it is apparent that nature seeks to prevent the entrance of portal blood into the general circulation, except by passage through the liver. The inosculations of the portal with the systemic veins are normally few and small, yet these inosculations always exist, and, in some healthy individuals, are numerous and comparatively large. In my former article[1] this matter was discussed at length. Since then the subject has been fully presented by F. Tischer, San Francisco,[2] who reproduced a diagram from Henlde's "Anatomy," showing the anastomosis of the portal vein with the superior vena cava, the inferior vena cava, and the azygos veins. Admitting that such inosculations exist, the question arises, why does not the portal blood pass directly into the general circulation? As a matter of course such passage of the portal blood would occur, provided the blood pressure of the portal was higher than that of the systemic veins, a state of affairs that undoubtedly sometimes occurs in disease: but normally this does not take place, because the portal blood pressure is lower than that of the other veins of the body.

So far as I know, Lauder Brunton[3] was the first to show the low blood pressure of the portal veins. His conclusions were confirmed by the experiments of Prof. Julius Pohlman, Buffalo, who demonstrated that in dogs, both while fasting and feeding, there was much lower pressure of the portal than of the systemic veins. The pressure was increased by feeding, but it never rose to a point equal to the general venous pressure. It is thus apparent that under ordinary conditions, even when the inosculations are numerous, the portal blood fails to contaminate the general circulation.

ATROPHIC CIRRHOSIS.

In atrophic cirrhosis of the liver the situation changes, and we find a high portal blood pressure, higher even than that in the systemic veins. If proof of this statement is needed, it may be found in the visceral congestion that attends the disease; further, in the dilatation of the portal veins, and, finally, in the increase in number and caliber of the inosculating vessels. In some cases of cirrhosis of the liver the intercommunications are so complete that the visceral congestion and ascites do not develop; or, having developed, they gradually subside. Meantime we have evidence of marked dilatation of those veins that are known to carry on a collateral portal circulation. Clinically, we recognize the dilated para-umbilical vein, the hemorrhoidal vein, and the esophageal vein, besides the new vessels in the adhesions that are often found between the liver or omentum and the abdominal walls. These vessels are seen dilated even in cases in which ascites and visceral congestion continue; but all of us have observed instances where there was marked evidence of this collateral circulation and where ascites has never occurred, although postmortem, the liver is found to be in a state of advanced cirrhosis. I have had the opportunity of following a number of these cases to autopsy; in several instances death took place through perforation of a dilated esophageal vein, leading to fatal gastrorrhagia. In some of these cases there was preceding toxemia worthy of more extensive consideration than I can present in this discussion. It is interesting to note that nearly all cases of fatal gastrorrhagia depending upon hepatic cirrhosis, that have come under my observation, have been exempt from ascites, or, if ascites were present, it was only as a terminal event. While this is not a universal rule, I find that, as to the frequency of this relation, the experience of others confirms my own. In other words, in those cases going to gastric hemorrhage, there is likely to be marked dilatation of the esophageal vein, *and although such dilatation exists, the blood pressure* in the portal vein and its branches continues so high as to endanger the thin vessel walls. It is generally admitted that many cases of cirrhosis of the liver escape ascites throughout their course, a fact which can be explained in no other way than by the establishment of free inosculations.

I have had the opportunity of studying for years several victims of toxemia, who never have had ascites, but in whom the liver is found, by all means of physical examinations, to be extremely small. One instance is that of a professional friend, Dr. P., in whom the liver can not be discovered by palpation and scarcely by percussion. More than ten years ago he was told by the late Dr. Loomis that he had cirrhosis of the liver, and such is my own diagnosis. This man is able to escape symptoms of toxemia only by resorting to light diet, consisting chiefly of milk and vegetables, and by taking every morning Friedrichschall water. If he indulges in proteids, especially shell fish, cheese or game, or takes any food in excess, he suffers, not from symptoms of indigestion, but from hebetude, dizziness, and disturbances of the urine that indicate toxemia. This man is 55 years old, and his condition has not apparently changed during the past ten years.

A similar case was that of J. C. L., a country attorney, aged 38. He had a history of typhoid fever when 23, but in other respects had been well, save that for the past ten years he had suffered from dizziness, disturbance of appetite, heavily-coated tongue, and great languor and depression. These symptoms had been more or less constant for several years when he visited me, in 1897. The physical examination showed that his liver could not be palpated; the liver dulness extended from the sixth to the eighth rib; over the liver could be heard, on auscultation, a distinct bruit, systolic in time. The patient was instructed to exclude certain articles of diet and was given Friedrichschall water. In fact he was treated much after the method adopted for my friend, Dr. P., and with similar results. The man has consulted me again within the last month, and he states that he is perfectly free from symptoms so long as he conforms to the directions, but that if he eats ordinary foods, especially those containing proteids that have undergone some decomposition, he immediately suffers, sometimes seriously, from the old symptoms. The history of this improvement under treatment extends over three and a half years.

Another very interesting case, seen with Dr. A. L. Benedict, was that of a man past middle age, a school teacher, who had always lived most carefully, but nevertheless suffered constantly from biliousness. He was compelled to keep to a light diet and to care for his digestive tract most carefully. A clinical diagnosis of contracted liver had been made several years before, although he had never had ascites. There had been no special change in his general condition when gastrorrhagia developed and proved fatal within a few days. The postmortem—the record of which I have mislaid—revealed a classic atrophic cirrhosis, with the portal vein greatly dilated, as were the vena azygos and the esophageal vein, from which latter vessel, through a "pin-hole" opening, the hemorrhage occurred.

In all of the above cases the men were very temperate. Another case, in which ascites occurred as a terminal event, was that of Mr. G., a railway engineer, seen in consultation with Dr. John Gray. The man had drank excessively of whisky for years. For a long time he had suffered from symptoms of indigestion and toxemia, which were usually attributed to alcohol. He had a muddy skin, distended capillaries, especially those around the abdominal region; his eyes were bloodshot, he was fat, and without much muscular strength. He attended to his duties as a railway engineer until a month before his death. Soon after stopping work he developed anasarca. Two weeks before death there was ascites, which required tapping; he died somewhat suddenly as the result of profuse gastrorrhagia.

Postmortem, made by Dr. F. G. Moehlau, showed the lungs much pigmented, emphysematous, free from adhesions, somewhat edematous at the posterior portions of the base. The heart was of moderate size, there was no pericardial effusion. There were red-stained vegetations on the tricuspid leaflets; there were also some thickened nodules along the margin of the mitral valves. All the valves were competent; the heart cavities were empty. The liver was light-yellow in color, universally hobnailed and cut with great resistance; the weight of the organ was about four pounds. The portal veins were dilated, but free from thrombi. The esophageal veins were tortuous and dilated, and apparently had for a long time carried on a considerable part of the collateral circulation. The azygos veins were not examined. The stomach contained several ounces of dark, fluid blood; its mucous membrane was highly congested and pigmented. The kidneys were macroscopically in good condition.

A similar case, seen in consultation with Dr. De Lancey Rochester, was that of J. C., aged 59, a business man, who had long been an alcoholic. He had complained of indigestion, bilious attacks, lassitude, and general muscular weakness. He was found to have an extremely small liver. He was under medical treatment at intervals for several years. Shortly before his death he developed ascites, and was tapped several times during the last weeks of his life. He died as the result of gastrorrhagia.

Postmortem made by Dr. H. U. Williams, eighteen hours after death, showed rigor mortis marked, moderate emaciation. On opening the abdomen, the omentum was found adherent to the anterior abdominal wall; liver adherent to abdominal wall, above and in front; liver at sixth rib on the right; pleural cavity free, and contained about two ounces of fluid; pericardium contained three drams of fluid. The lungs crepitated well and showed some edema, otherwise not important. The heart was large, pale, supercardial fat was found normal, wall of right ventricle thin; valves normal; moderate sclerosis of coronary arteries and aorta. Spleen was large, capsule thickened, on section not remarkable. Kidneys and bladder not remarkable.

The liver was deformed by the adhesions mentioned; the adhesions were marked in the neighborhood of the common bile duct. The gall-bladder contained one ounce of greenish bile; no calculi. The liver was very friable; on section it was shown to be cirrhotic and fatty. The pancreas was small, pale, fatty. The veins at the lower end of the esophagus were markedly dilated. The mucous membrane of the stomach appeared normal, its contents contained dark, reddish streaks. The ileum contained apparently fresh blood; there was no blood in the remainder of the intestines. The source of hemorrhage could not be found.

Another case, E. B., died at the Buffalo General Hospital, aged 41; the patient had been an alcoholic and died as the result of severe and repeated gastrorrhagia.

The autopsy, made by Dr. H. U. Williams twenty-four hours after death, showed rigor mortis firm; slight lividity; abdominal cavity contained a large quantity of straw-colored fluid. The omentum was adherent to the anterior abdominal wall, and the peritoneum was greatly thickened; much fibrin was present on the abdominal surfaces of the intestines. The inner muscular tissue of the abdominal wall showed edema. Fluid was found in both pleural cavities and in the pericardial sac. The heart was small, pale with normal valves; the cavities empty; the muscle pale, firm and of the usual thickness. The aorta and coronary were normal; the bronchial tubes were coated with bloody mucus; both lungs showed edema; the veins on the pleural surface of the diaphragm in the neighborhood of the esophagus, also the veins in the lower part of the esophagus and the cardiac end of the stomach were dilated and prominent. Three inches above the stomach, on the posterior aspect of the esophagus, the mucous membrane showed reddened, denuded areas the size of a lead pencil; the esophagus and the stomach were both dilated and prominent. Efforts were made to show an anastomosis between the veins of the lower part of the esophagus with the gastric veins, but these were only partially successful. The esophagus, stomach and intestines all contained blood. The liver weighed 3 pounds, 3 ounces, was coarsely lobulated and its capsule very thick. On section, the parenchyma was lobulated, and traversed by bands of fibrous tissue. The parenchyma was pale, soft, and in some places bile stained. The spleen weighed 14 ounces, with greatly thickened capsule; other organs were not remarkable. The hemorrhage was believed to have sprung from the denuded areas in the esophagus.

Another case was that of F. W. T., aged 59; a business man of high standing and strictly temperate habits. He had cholera in 1852, but otherwise had escaped sickness until six months before, when he suffered from pulmonary congestion secondary to dilatation of the heart. He had sclerosed arteries, pulmonary emphysema, an extremely small liver and a large spleen. He reported that for many years his appetite had been very slight and he had felt better when he ate sparingly. Of late his appetite further declined, and he showed evidence of marked toxemia, which was partly owing to poor elimination. The bowels were irregular, skin muddy and loaded, and the urine showed traces of albumin, containing 18.30 grams of urea in twenty-four hours and cylindroids. The man was benefited by taking Friedrichschall water, vapor baths, and a course of medical gymnastics. He was found on the floor of his bathroom in syncope, having vomited a large amount of blood. The hemorrhages were repeated during the next forty-eight hours, when he died. A rather remarkable coincidence in this case was that the hemorrhage had been predicted, because of the marked evidence of cirrhosis, the dilatation of the superficial abdominal veins, the absence of ascites, and the presence of the toxemia. It was believed that the inosculating vessels must be much dilated, and judging from the condition of the arteries, it was assumed that the veins were becoming weak. No autopsy was permitted. Here was another case of marked cirrhosis terminating in fatal gastrorrhagia in which ascites never appeared.

It is not uncommon, as I have stated, to find cases of cirrhosis without ascites dying from various affections. In these cases it will be quite uniformly found that the communicating veins are enlarged, or that new vessels have been formed through adhesions; but ascites may be absent even without the presence of adhesions, as the following case illustrates:

Mrs. A., Buffalo General Hospital, March 6, 1899. The patient was 65 years old; dead 36 hours; nutrition poor, lungs showed old disease; the pleural and pericardial cavities were dry; heart showed fatty infiltration and degeneration as proved by microscopic examination; marked sclerosis of the aorta and somewhat of the coronaries. The liver weighed 3 pounds, 13 ounces; the surface was yellow and granular; the lobules distinct; the veins of the stomach and duodenum were dilated; the spleen was enlarged, soft and dark. Other portions of the history are omitted.

In the absence of data in some of these cases it can not be proved that all suffered from toxemia, the result of inosculations; but in most of them it is so highly probable that it may be assumed.

CONCLUSIONS.

From the facts stated, I am led to conclude that the passage of the portal blood into the general circulation, without having traversed the liver, is a source of toxemia that produces definite symptoms. This view, which I propounded in 1889, was not accepted by the gentleman who did me the honor to discuss my paper, but further observation convinces me that the view is correct. We now have the opportunity for experimental proof of this explanation of toxemia in cirrhosis of the liver, in cases of epiplorrhaphy for the relief of chronic ascites, the result of hepatic cirrhosis. My attention was first called to this in a report by Mr. Rutherford Morrison,[4] in which he speaks of a "peculiar toxic condition, with sallowness and drowsiness, which sometimes followed the operation and was relieved by purgation." In other words, by lowering the portal blood pressure. In discussing this communication, Dr. Beattie stated that "Such a toxic condition was known in medicine, and cited three cases where drowsiness had gone on to complete coma, and was sometimes associated with hematuria. It commonly occurred in cases of cirrhosis without ascites, where collateral circulation had been well established by a large vein of Sappey."

Besides the cases of epiplorrhaphy reported by Morrison,[5] numerous cases have been reported both in this country and abroad. A notable contribution is that made by Packard, Philadelphia,[6] with which you are all familiar, and in which reference is made especially to the toxemia that follows operation.

Another case in point is one of twenty operated upon for deviation of the blood in the portal veins, reported by B. Schiassi.[7] The patient, a young man, had suffered from cirrhosis of the liver for ten years, with constantly recurring ascites. Since the operation he has gained twelve kilograms in weight, and at present has but a few cubic centigrams of fluid in the peritoneal cavity. During the third and fourth week after the operation intense dyspnea and profuse sweating, with slight fever, appeared after eating some raw eggs. These symptoms disappeared when the diet was restricted to carbohydrates.

S. Salaskin and J. Zuleski[8] report experiments showing that in dogs in which was allowed a communication of the portal veins with the vena cava, symptoms of ammonia and carbonic acid poisoning appeared, apparently as a result of the relative inactivity of the liver. Complete extirpation of the liver leads to increase in the general content of acid in the body, as is shown by the acid increase in the urine.

Two practical conclusions may be drawn from these data. 1. The fact, to which it would seem unnecessary to call attention but for the reason that it appears to have been somewhat overlooked, that the normal blood pressure in the portal vein is low; that when it is suddenly raised it is apt to be followed by symptoms of toxemia, and that these symptoms may be promptly relieved by purgation. 2. The important conclusion that, when the vascular changes and the raised portal blood pressure that permit the passage of the portal blood into the systemic vein are brought about gradually, the subject is better able to resist the toxemia, becoming, as it were, immunized to the offending portal blood, hence symptoms are less striking, and with proper care as to diet and purgatives may be practically overcome.

ROENTGEN RAYS IN THE TREATMENT OF DISEASES OF THE SKIN.

A REVIEW OF RECENT LITERATURE AND A PERSONAL EXPERIENCE.*

WILLIAM ALLEN PUSEY, A.M., M.D.

Professor of Dermatology in the College of Medicine of the University of Illinois.

CHICAGO.

A little over a year ago I reviewed the literature of the use of Roentgen rays in the treatment of diseases of the skin.[1] The subject is of active interest and there have been frequent contributions to it during the last year, so that I trust I am warranted in bringing the review down to the present time and adding to this a brief account of my own experience. In general it may be said that the experience of the last year has been strongly confirmatory of previously made claims for the value of the method. Recent reports have not established new fields of usefulness for the method, but they have put us in a position to appreciate more accurately the indications for it and to form a better opinion of its value.

An analysis of clinical reports and of the reports of microscopical studies of tissues affected by *x*-rays indicates broadly that this method of treatment may be of use in the following conditions: 1, in conditions where it is desired to produce an atrophy or partial atrophy of some of the appendages of the skin, as in hypertrichosis; 2, in mycotic diseases, such as tinea tonsurans, favus and sycosis; 3, in chronic inflammatory affections, such as indurated patches of eczema and lupus erythematosus, where the purpose is to stimulate the tissues and cause absorption of inflammatory products; 4, in certain specific affections, such as lupus and epithelioma, where the purpose is to cause the destruction of tissues of low vitality.

---

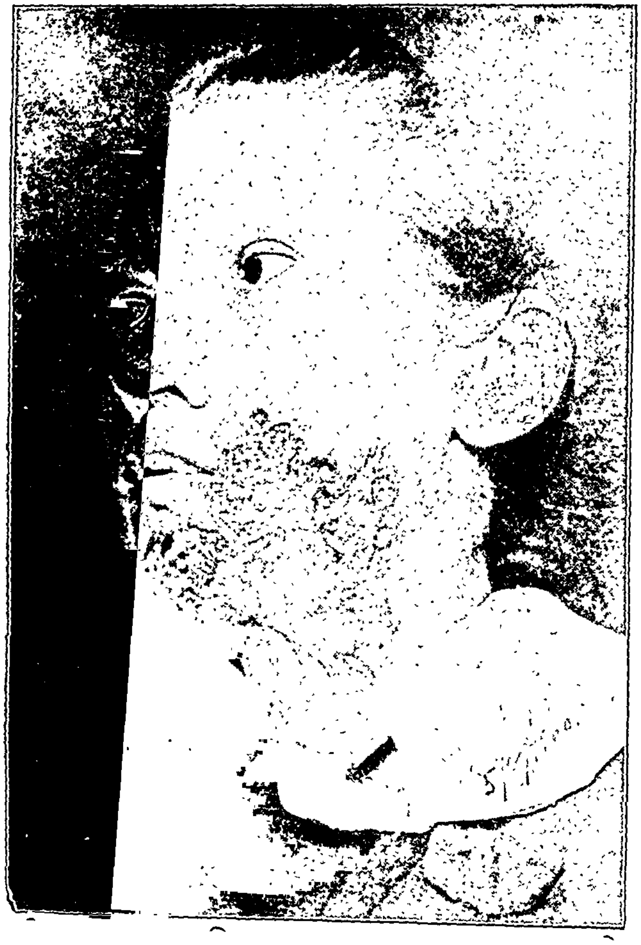
REMOVAL OF HAIR.

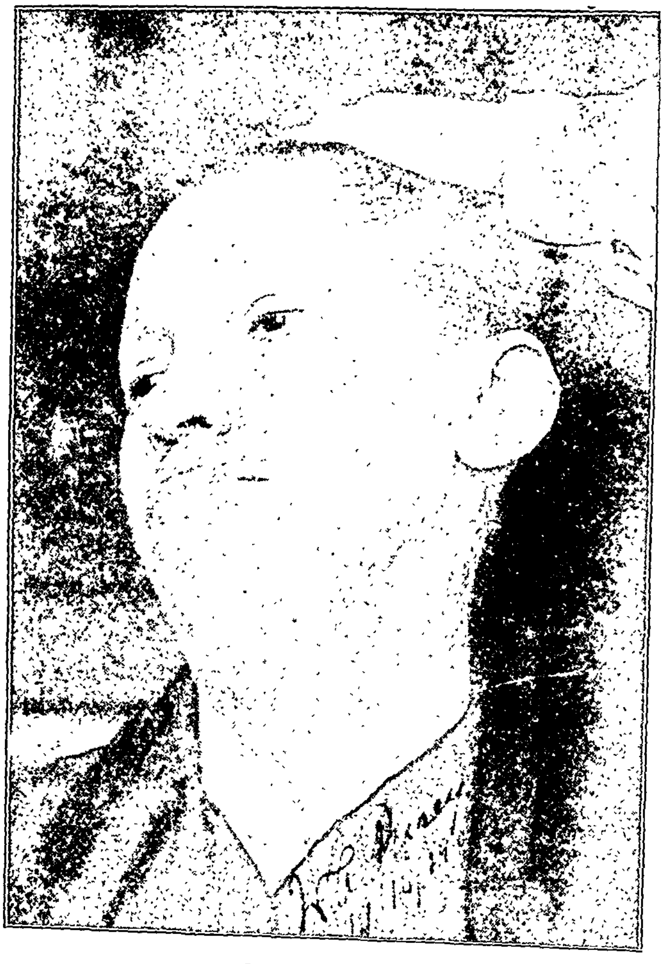
As Oudin Berthelemy and Darier have shown, the effect of *x*-rays upon the epithelial structures of the skin is to increase the vitality of the least differentiated skin elements, while the differentiated elements—hair, nails and glands—undergo retrogressive changes and atrophy. It is this effect of *x*-rays that is useful for the removal of hair. Freund was the first to suggest the use of this agent for this purpose, and he and Schiff have perhaps done more in this direction than anyone else. I had the opportunity of investigating their work during the summer of 1899 in Vienna; I found that observers, who had seen their work from the beginning, had no doubt that they were able to produce permanent alopecia by their method of using *x*-rays. Their claims in this direction are being confirmed by many other observers. One of the most interesting cases of this sort was reported by Neville Wood; in this case a profuse growth of down and large hairs was removed from the chin by the use of *x*-rays, and there was no recurrence eight months after the cessation of the treatment. Startin has reported four cases in which he has successfully used this method for the removal of superfluous hairs with results that were permanent after several months. Jutassy has reported similar cases.



Case 1.—Fig. 1.

My own experience in the treatment of hypertrichosis by this method now extends over about a year. I have 9 cases in which treatment began not less than four months ago; 2 of these were compelled to give up treatment before results could have been expected. In the 7 other cases partial or complete alopecia has been produced. In only 1 case has the result failed to satisfy the patient. The following 2 cases have been longest under treatment and show the most striking results:

Case 1.—Miss A., brunette, age 22, with a profuse growth of coarse black hairs from half an inch to an inch and a half long on chin and upper lip. The growth was not less than that found on many men of the same age and was very disfiguring. After twenty-seven exposures, which were given at the rate of five or six per week, some erythema and pigmentation developed and treatment was discontinued for a month, during which time these manifestations entirely disappeared and many hairs came out. Sittings were renewed until twenty-five more were given, when erythema developed and treatment was discontinued for three weeks. During this intermission there was continuous falling of the hairs. By the end of three weeks almost all the hairs on the chin had come out and a great many on the upper lip. Sittings were renewed after three weeks and twenty-four sittings were given, when considerable erythema developed. Upon the occurrence of this third reaction all of the remaining hairs came out from the lower part of the face and only a few fine hairs were left on the upper lip. Three months after the stopping of exposures the patient came back with the recurrence of a very few hairs; these were small and not conspicuous, and after nine sittings they all fell out. The last sitting was given March 28 and up to the present there has been no recurrence. The entire improvement is remarkable; the skin is white, smooth and perfectly normal in appearance, and aside from the absence of hairs her complexion is unquestionably better than it was before treatment began.



Case 1.—Fig. 2.

CASE 2.—Miss B., age 26, with an abundant growth of brown, coarse hairs, the longest over an inch long, on lower part of face and upper lip, greatly disfiguring an otherwise attractive face. The course in this case was very similar to that in the preceding, except that results were produced with less difficulty, and only slight erythema was ever produced. Sixty-seven sittings in all were required to cause entire removal of the hairs, and there is no recurrence up to the present. The patient's skin is in good condition, and shows similar improvement in appearance to that observed in the first case.

These two are, with one exception, the most exaggerated cases of hypertrichosis that I have treated. In four of my cases the course has been somewhat different from that outlined above. In these, there has not been a rapid fall of hairs at one time, but they have gradually fallen out week after week until the number remaining is very few, without complete alopecia. While the results in these cases are not so striking to report, they have been equally as satisfactory to the patients. The falling of the hairs has been very like a rapidly progressing alopecia from natural causes. In two cases, sisters, the result has been attained with more difficulty, owing to the appearance of a slight dermatitis, which was very slow to disappear. In one of these cases the erythema and pigmentation lasted four months. It was, however, only slight and not sufficient to cause the patient any annoyance. During this time there was constant but gradual thinning of the hairs, so that the patient to-day, while still showing a good many lanugo hairs, has no coarse or long hairs left.

I have found that it takes a greater number of sittings to cause outfall of the hairs than Schiff and Freund and other observers report, but this may be due to the fact that I have pursued the treatment with great caution. The time required for the removal of the hairs the first time has varied, in my cases, from twenty to sixty-six sittings; the removal of recurrent hairs has required from five to fifteen sittings. According to the observations of Schiff and Freund, recurrence of a few hairs must be expected at intervals of from four weeks to several months, until a year and a half has passed; these hairs must be removed as they recur. In none of my cases has sufficient time elapsed to justify an opinion as to the permanency of the result, but in the length of time that the hairs remain away after their removal and the ease with which the recurrent hairs are removed, my experience confirms the claims of Schiff and Freund.

In no case, except the first one detailed above, has any considerable dermatitis developed. The cases usually show slight erythema or pigmentation after three or four weeks of daily sittings, and then in a few days the hairs begin to come out. If treatment is stopped at the first appearance of these symptoms the erythema rapidly disappears; the pigmentation is somewhat slower to disappear. My experience in treating hypertrichosis indicates, contrary to the statements of some observers, that with all the factors that determine the strength of the light the same individuals vary considerably in their reaction to the rays. I have been able to cause falling of the hair in some cases by as few as twenty exposures; in another case it required sixty-six exposures. In some cases erythema appears without pigmentation; in others erythema and pigmentation appear together, and in different cases the relative degree of erythema and pigmentation varies. In a recent case the course of treatment has been complicated by the early appearance of very considerable pigmentation, which has proved very slow to disappear. In my experience the reaction of different individuals to *x*-rays is very similar to their reaction to sunlight. Skins which burn rather than tan under sunlight develop erythema rather than pigmentation under exposures to *x*-rays, and skins which tan without burning show greater pigmentation under *x*-rays. In some cases the hairs fall rapidly upon the occurrence of erythema or pigmentation; in others they come out slowly for weeks after the production of these symptoms and the stopping of treatment.

It is not to be lost sight of that atrophy of the other appendages of the skin occurs to a greater or less degree along with the atrophy of the hair follicles, and it is conceivable that this might produce an injurious effect upon the skin. In the cases which I have treated the action of the rays upon the skin has caused distinct improvement in its appearance. In all of my cases, after the disappearance of the erythema and pigmentation, the skin of the parts treated has been left smooth and soft, of good color and healthy appearance. Some of these cases have had slight acne and following exposures the acne and the commedones have disappeared. During the existence of the erythema the affected areas have shown increased sensitiveness to local irritation, particularly to exposure to cold winds, but after the disappearance of the erythema the skin has shown no lowered resistance. The increased sensitiveness to cold has disappeared and the areas treated have shown themselves to be quite as tolerant of local irritants as other parts.

ACNE.

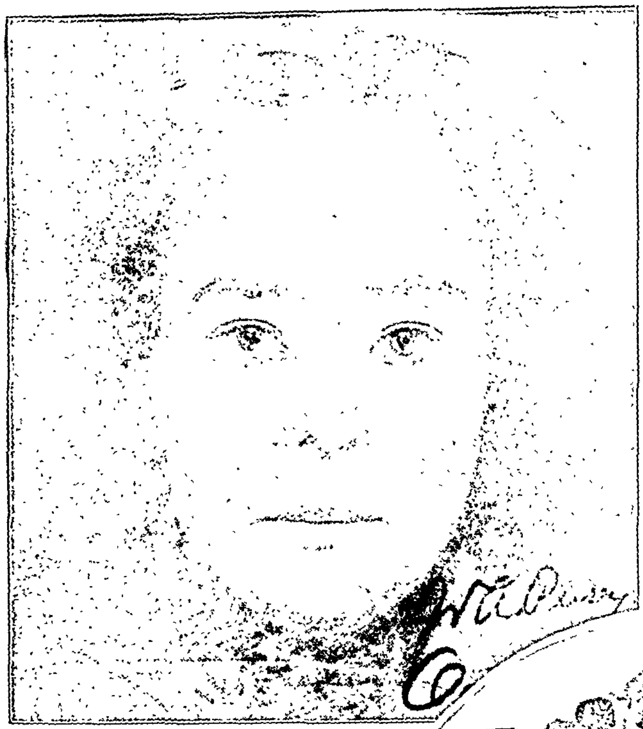
The fact that the sebaceous and sweat glands are similarly, though to a less degree than the hair follicles, affected by the *x*-rays suggests the possibility of the use of them for the treatment of disorders of these glands. and a number of favorable reports of the treatment of acne by this method have been published. Upon theoretical grounds there is good reason to believe that this method has a field of usefulness in treating acne. There is another property of the rays, in addition to the property of causing atrophy of the appendages of the skin, that probably comes into play in treating acne, and that is the property of inhibiting the formation of pus. This property of the rays will be referred to again in considering Zechmeister's case of sycosis parasitica treated by this method. Whether the rays have any bactericidal properties or not—a point which seems still open to question—there can be no doubt as to the inhibitory influence of *x*-rays upon the formation of pus in the skin.

HYPERIDROSIS.

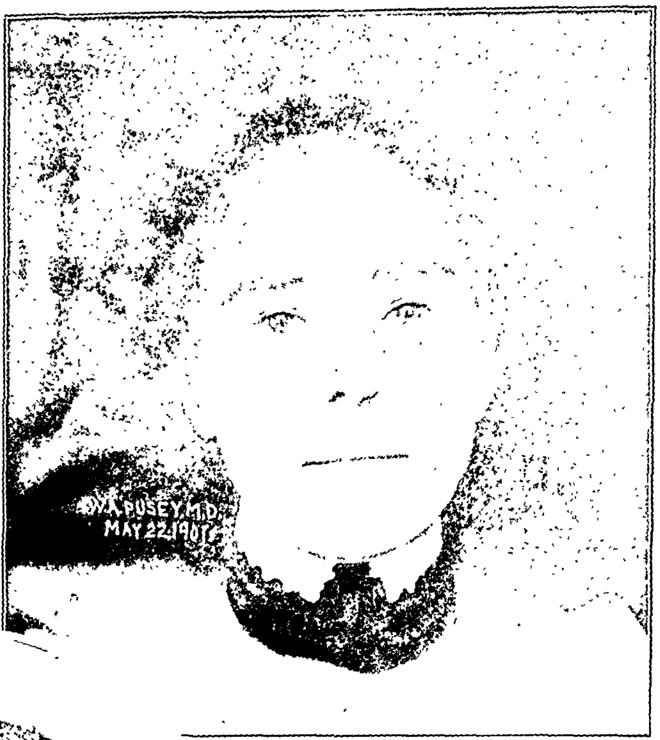
The effects of *x*-rays are perhaps less upon the sweat glands than upon either the hair follicles or the sebaceous glands. There seems to be, however, some theoretical ground for believing that the method may be useful in local forms of hyperidrosis. So far as I know, no one has suggested the use of the rays in these cases. I have not tried the experiment myself, but believe there is sufficient ground to warrant its trial in intractable cases of hyperidrosis, as, for example, of the axillæ or of the feet.

TINEA TONSURANS AND FAVUS.

In tinea tonsurans and favus the use of *x*-rays has been highly recommended by Schiff and Freund, who report rapid cures of these conditions by this method. I know of no reports upon the subject within the year.



Case 2.—Fig. 3.



Case 2.—Fig. 4.

Case 4.—Fig. 5.

Case 4.—Fig. 7.

SYCOSIS.

The use of *x*-rays in the treatment of sycosis was first suggested by Schiff and Freund. I had the opportunity of observing some of their cases in Vienna two years ago, and I believe that in cases of deep-seated parasitic sycosis there is no other method of treatment that compares with this. Other observers are confirming the results obtained by Schiff and Freund in the treatment of this disease. Gassman and Schenkel have reported, to use their own words, "an unquestionably favorable result" in a case of non-parasitic sycosis. Zechmeister has given a careful report of a successful case treated by this method. This was a case of deep-seated parasitic sycosis of two years' standing in spite of persistent treatment in which the disease disappeared entirely within a month under *x*-ray exposures. Without the use of antiseptics the pustules rapidly dried up, and the subcutaneous abscesses disappeared without incision. There can be no question that in the use of *x*-rays we have a most valuable method of treating this very intractable affection.

LUPUS ERYTHEMATOSUS.

The utilization of this method in treating chronic inflammatory affections of the skin has been confined chiefly to the treatment of eczema and lupus erythematosus. Schiff, Jutassy, and Hall Edwards have reported cases of lupus erythematosus treated by this method. Improvement and even cures are reported, but in a disease so uncertain in its course as lupus erythematosus, conclusions as to the value of any method of treatment must be very carefully drawn. The efficacy of this method in the treatment of this condition requires for its determination a much larger experience. It is recommended by theoretical considerations.

ECZEMA.

Favorable results in the treatment of eczema have been reported by a number of observers, among them, Jutassy, Holland, Mackay and Hahn and Albers-Schoenberg. Practically the same may be said of the treatment of eczema by *x*-rays as was said of the treatment of lupus erythematosus. I see no reason to change the opinion which I ventured a year ago, viz., that the cases of eczema, in which this method of treatment seems to have a field of usefulness, are those with very intractable, circumscribed patches of eczema, in which there is necessity for marked stimulation of the skin in order to get absorption of the inflammatory products.

LUPUS VULGARIS.

The reports of last year upon the treatment of lupus vulgaris with *x*-rays strongly confirm the previous claims for its value. Cases have been reported by Jutassy (1 case), Gassman and Schenkel (4 cases), Hall Edwards (2 cases), Scholefield (1 case), Knox (1 case), and 1 case by the writer. Knox's is the second case reported in the United States, the first case having been reported by Jones, San Francisco, two years ago. My first case was reported two weeks later than Knox's. There can be no question as to the accuracy of the diagnosis in all of these cases. The length of time that they have been well varies from a few weeks to two and a half years. Among Gassman and Schenkel's 4 cases, 2 cases had relapses, 1 at six, the other at seven months after stopping exposures, but that so mischievous a disease as lupus should recur in rare instances after any method of treatment is hardly surprising.

I have treated three cases of lupus vulgaris by this method. The condition of Case 1, at the beginning and at the end of treatment, is shown in the accompanying portraits (Figs. 1 and 2).[2] The last exposure given to this patient was on Jan. 12, 1901. The patient remains well at the present time with perfectly healthy scars. I will exhibit her at our clinical meeting.

CASE 2.—Girl, age 18, referred to me by Dr. A. J. Ochsner, with a diagnosis of lupus, for treatment with *x*-rays. It was a typical lupus of the nose involving tip, alæ and septum. The disease began four years ago on the tip of the nose and gradually spread to its present extent in spite of persistent treatment. The patient had been under Dr. Ochsner's treatment for two and a half months and during this time the condition had greatly improved. The photograph herewith presented (Fig. 3) shows very well the condition at the time she came under my care. The entire tip of the nose and alæ were a mass of reddish-brown, soft, friable, apple-jelly, lupous tissue. The middle half of the upper lip was covered by similar tissue, some of which was ulcerating, and scarred. The disease had also involved the mucous membrane of the nasal orifices and septum. Exposures were begun on October 1, and were given almost daily until December 20.

With the exception of a reddening, sharply confined to the lupous area, which occurred after thirty sittings, there was no change in the condition until the middle of December, when considerable redness developed in the lupous tissue and slight redness in the surrounding healthy part which had been exposed. As the lesions had proven quite intractable, exposures were continued until ten more were given. On December 20, after sixty-four exposures, treatment was stopped on account of dermatitis and tenderness of the exposed surfaces; on December 28, without further exposures, a not very tense bulla, the size of a thumb-nail, developed on the tip of the nose, where the effect of the light had been greatest. This was accompanied by tenderness and slight pain. Within a week most of the dermatitis subsided, the bulla ruptured, and at its site there showed a very superficial ulceration. This bled easily, was quite painless after a few days, and was covered with a superficial necrotic membrane. Its borders rapidly contracted, and on January 20 it had entirely healed. With the healing of this surface almost all traces of lupus disappeared. There was left only a small suspicious area, the size of a little finger-nail, on the right ala; to remove this, exposures were given, at from one to two day intervals, during February and March. After thirty sittings this spot on the ala of the nose became red and swollen, and these manifestations were quickly followed by a very remarkable softening of the lesion, so that it felt as soft as a flaccid bulla, without, however, any suspicion of a separation of the epidermis occurring. This redness and softening was quickly followed by the disappearance of the last suspicious area. From the beginning of treatment up to the time of the disappearance of the last lesion, March 16, 1901, she had ninety-five sittings, extending over a period of six months. Since the disappearance of the last lesion she has had irregular exposures simply as a precaution. She has been for two months free from any evidence of the disease. The condition at present is shown in the accompanying photograph (Fig. 4), and I will exhibit the patient at our clinical meeting.

The results, from a cosmetic standpoint, is, I believe, as perfect as can possibly be expected. There is some diminution in the size of the nose, but aside from this there is no deformity. There is entire absence of scarring in all of the areas treated by this method; the only scars are those on the upper lip resulting from ulcers which healed before this treatment was begun. The skin is soft, pliable and natural in appearance. I do not believe that as good a result as this is possible under any other method of treatment, except Finsen's. The only local treatment that this patient had was boric acid vaselin applied to the tip of the nose during the time it was inflamed by *x*-rays. She had no internal treatment whatever.

CASE 3.—Woman, age 41; occupation, trained nurse, with lupus of the face of twenty-five years' duration. This is a very extensive lupus, which has had vigorous treatment for many years. Two and a half years ago, an attempt was made at extirpation of the disease surgically, with restoration of the face by plastic operations. The disease promptly recurred. This patient has been under my care for six months. The transplanted tissue has proven very irritable to x-rays, so that it has been impossible to give her vigorous treatment.

---

[2] This case was reported in THE JOURNAL A. M. A., Dec. 8, 1900, and the reader is referred thereto for a full history of the case.

There is considerable improvement in the condition, but the disease is by no means cured, and I present the case only that my report may be complete.

CARCINOMA.

The most interesting development of the last year in the use of x-rays has been in the treatment of cutaneous carcinoma. There are reports of favorable results previously, but the accumulation of evidence in favor of the treatment by x-rays has taken place within the last year. Cases have been reported by Stenbeck (1 case), Johnson and Merrill (6 cases), Sequeira, London Hospital (12 cases), Smith (1 case). In practically all of these cases the diagnosis is beyond question. In most of them confirmatory, histological diagnosis was made. The results are not in all cases cures, but in all cases there is unmistakable evidence of the beneficial influence of the rays. Stenbeck's case is a cure of a rodent ulcer of the nose. Everett Smith's case is similar. Of Johnson and Merrill's cases, three epitheliomas of the nose are entirely cured, as far as can be determined in the time that has elapsed. One epithelioma was not entirely cured, but showed great improvement. One recurrent carcinoma of the breast had, after four weeks, shown an improvement in the patient's health and disappearance of pain. One case stopped treatment after a very few exposures. Of Sequeira's twelve cases, three cases were apparently cured; these cases have been demonstrated before the London Dermatological Society. The other nine cases were still under treatment and showed more or less improvement, according to the length of time treated. Williams, Boston, has reported favorable results in epitheliomas treated by this method, including a report of one case which is apparently cured.

I have treated one epithelioma by this method:

Case 4.—Mrs. C., age 68, with the following history, most of which is taken from the records of St. Luke's Hospital. About twenty years ago a wart appeared in the right supraclavicular space and gradually increased in size. Three years after its appearance the surface broke down and an ulcer developed, which, after two years' duration, was excised by a well-known Chicago surgeon.

The disease recurred in the upper angle of the scar and enlarged until 1894, when she came to St. Luke's Hospital. It was then the most extensive epithelioma I have ever seen, covering almost the entire upper third of the back, and extending over the right shoulder to the clavicle. I fortunately photographed her at that time.

During 1894-5 she was in St. Luke's Hospital, in the services of Drs. John E. Owen and L. L. McArthur, where vigorous attempts were made to extirpate the diseased tissue. A large part of the tumor was destroyed and extensive grafts were made, so that the diseased area over the back was converted into scar tissue, which has remained healthy until the present. The area over the right shoulder, from the spine of the scapula behind, to a point below the clavicle in front, an area covering the entire upper surface of the shoulder, was not cured.

From that time until this winter she has been more or less constantly an out-patient at St. Luke's and for two years past it has not been thought feasible to make any further attempt at extirpation of the growth. The extent of the growth, at the time she presented herself for treatment with x-rays, is shown in the photograph (Fig. 5) presented herewith. As shown in the photograph, the disease involved the greater part of the area over the right shoulder. The largest lesion was situated at the juncture of the neck and shoulder, and consisted of three confluent ulcers, forming in all an ulcer with a diameter of about three inches. This was a typical epitheliomatous ulcer with elevated, rolled, hard, pearly borders. In addition, there were perhaps twenty other epitheliomatous ulcers, varying in size from a finger-nail to a small pea, located around and posterior to the large ulcer. Extending down over the front of the shoulder was a triangular space with the apex below the clavicle, which contained numerous small epitheliomas. Some of these were ulcerating, but most of them were intact nodules.

All of the tissue of the affected area was inflamed and indurated. There was no evidence of involvement of contiguous glands or of the underlying tissue. There was free discharge from the ulcers and for many years the patient had suffered severe pain. Tissue for examination was excised from the border of the large ulcer and sections of this are presented to-day. [Only one illustration is given here, namely, Fig. 6, the central photomicrograph of the insert.] The tissue presents the typical histological picture of superficial epithelioma (Fig. 6). The tissue has also been examined for blastomycetes, which were absent.

Through the courtesy of Dr. Porter, who was an interne at St. Luke's during her residence there, I am able to show a section that was made seven years ago. This section also shows characteristic epithelioma.

The patient was put under exposures to x-rays on Jan. 15, 1901, and had almost daily sittings until February 14, eighteen in all. Within a week the discharge from the ulcers almost entirely ceased, and the patient volunteered the statement that her shoulder was free from pain and that she was able to sleep comfortably for the first time in many years. Since this first week there has been practically no discharge from the ulcers, and almost no recurrence of pain. The disappearance of the discharge was the more interesting because before the patient came under treatment with x-rays she had been a regular attendant at St. Luke's Hospital out-patient department, where her shoulder had been dressed as often as necessary.

On February 4 the ulcers were decreasing rapidly in size, and, what was more significant, the rolled edges were shrinking. On that date, the patient was hurt by a fall and was not able to appear for further exposures until March 13. In the interval she was in the Charity Hospital, where, at my request, the physicians kindly saw that no change in the local treatment was made from my application of boric acid vaselin.

She returned for treatment on March 13, and from March 13 to May 4 she had twenty sittings, varying from daily sittings to sittings at intervals of from four to five days. By April 5, the evidences of epithelioma were limited to a small ulcer not larger than a little finger-nail at the site of the previous large ulcer, and to two rows of very characteristic nodules in the supraclavicular space.

Up to this time the exposures had always been made so that the greatest intensity of light fell on the shoulder, and the lesions over the clavicle, therefore, had received less of the rays. After April 5 the upper surface of the shoulder, which had been getting exposures of fifteen minutes, was given exposures of five minutes, and the lesions over the clavicle were given direct exposure of fifteen minutes. Within five days after beginning these exposures over the nodules in the supraclavicular space a very remarkable change was noticed in them. They began to shrink and to disappear rapidly.

By April 16, that is, after ten direct exposures of fifteen minutes each, these nodules had entirely disappeared. They were absorbed and disappeared, leaving no trace of their existence, without dermatitis or any breaking-down occurring. Sittings were discontinued on April 16, as the shoulder showed slight dermatitis.

By April 29 this irritation had entirely disappeared. Between April 29 and May 8 the small ulcer on the upper surface of the shoulder, the last trace of epithelioma, entirely healed. Her condition at present, and since May 6, is shown by the photograph (Fig. 7).[3]

I particularly call attention to the character of the scars. They are called scars for lack of a better term, but there is hardly any evidence of scar tissue. The skin is smooth and soft without contractures and shows practically no trace of the previous ulcers. Whether this case is a cure or not time can only determine. There is no evidence of epithelioma remaining and, as far as can be told in the length of time that has elapsed, the case is cured. Regardless of the possibility of recurrence, I believe the result may still be called remarkable.

---

[3] All the patients whose photographs are shown were presented at the clinical meeting of the American Dermatological Association. All of them remain well at present, Sept. 1.

The only local treatment which the patient received while undergoing this treatment was the application of a cloth covered with vaselin containing one dram of boric acid to the ounce, and the occasional wiping of the surface with cotton sponges wrung out of a bichlorid solution. There has been no care exercised to keep the surface free from contamination with pus organisms and in spite of conditions most favorable to infection the ulcers remained clean and almost entirely free from discharge. The only internal medication which the patient had was compound syrup of hypophosphites during the month of April, when she was much depressed from chronic bronchitis.

I have also treated, by this method, a recurrent carcinoma of the breast. This case was only undertaken after further surgical intervention had been refused by her surgeon, a man of well-known standing. This patient remained under treatment four weeks. There was, in her opinion, a lessening of the pain and she certainly improved in her general health, but there was no perceptible effect upon the tumor, and, as the patient was compelled to be away from her family in order to have the treatment, at my suggestion, the treatment was not carried further. It seems hardly to be expected that the method should be of service in inoperable carcinomas of the breast, with their extensive metastases, nevertheless the method deserves a trial even in these desperate cases. In this connection it is not to be forgotten that Williams has reported a case of epithelioma of the lower lip, treated with *x*-rays, in which the enlarged gland, under the inferior maxilla, disappeared after the lip was healed.

Dr. T. A. Davis has suggested to me the use of *x*-ray exposures after removal of carcinomas of the breast as a means of preventing recurrence of the disease. With the facts before us as to the destructive influence of *x*-rays upon carcinomatous tissue, this ingenious suggestion is worthy of trial, not only after removal of carcinomas of the breast, but also after removal of carcinomas in other superficial locations.

In my cases I have followed the technique suggested by Schiff and Freund, and it meets all of the requirements of accuracy and safety. This technique has been described in my previous article. Of course, the application of *x*-rays, whether for the removal of hair or for other conditions, must be made with great caution. To this end it is necessary that all of the factors involved in producing the light be definite and that there be repeated exposures to a weak light, the effects of which may be controlled, rather than the use of a strong light for a few exposures. The treatment should be interrupted at the first indication of reaction. The work should not be undertaken with static machines or with the ordinary apparatus used for diagnostic purposes.

The question of the effects produced upon tissue by *x*-rays, and of the factors in the rays which produce these effects, I considered in my previous article and I shall not take time to go into a full consideration of these again. I will venture the opinion that the reasons are constantly becoming stronger for believing that the effects of *x*-rays are due to the peculiar *stimulation* of the tissues which they cause, and not to any strong bactericidal effects in the rays themselves. As to the active factor in the rays, I repeat, with increasing assurance, the opinion offered a year ago, that the essential factor is something in the rays themselves and not, as has been suggested, some incident of their production, like ozone, or brush discharges, or induced electrical currents in the tissues, or particles of platinum carried off from the anticathode. As Prof. Elihu Thompson expresses it, in discussing some experiments on the point, "There is only the supposition left that the effect was produced by Roentgen rays or something that comes with the rays." The lesser degrees of *x*-ray burns resemble sunburns more closely than any other pathological process, and there seems to be no good reason for not believing that the effects of *x*-rays on the tissues are due to the actinic rays of the *x*-rays, just as sunburn is due to the actinic rays of sunlight. That certain of the *x*-rays are strikingly similar in their actinic properties to the rays of light at the violet end of the spectrum is shown by their similar effect on photographic plates. And it is no violence to the reason to suppose that the same actinic properties of the *x*-rays that cause rearrangement of molecules and the formation of new salts on photographic plates can exercise a similar power on the molecular arrangement of tissue cells and influence their metabolism. I am more fully convinced than ever that the active rays among the *x*-rays are identical, or at least so similar in all of their properties as to be practically identical, with the rays at and beyond the violet end of the spectrum. If this is true this method of treatment is identical in principle with that of Finsen, and I am willing to record myself as holding the opinion that such is the case.

CONGENITAL CYSTIC KIDNEY.*

WILLIAM JEPSON, B.Sc., M.D., L.R.C.S. Ed.
SIOUX CITY, IOWA.

In accepting the opportunity kindly offered me by the Chairman of this Section to present the clinical history of a case of unilateral cystic kidney in a child of 4 months and 14 days, I am actuated by the hope that the rarity of the condition, at least as far as I am able to determine, may elicit a degree of interest which would otherwise not be merited by the report.

The salient points in the case, briefly stated, are the following: The child, Freda W., female, born July 13, was the second child of German-American parents; from the time of birth until 2 or 3 days prior to securing this history she was seemingly possessed of perfect health. November 27, Dr. Stidworthy was called to see the child on account of vomiting and constipation, no evacuation of the bowels having occurred for nearly 48 hours.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee of the Section: Drs. H. E. Tuley, Edwin Rosenthal and Samuel W. Kelley.

On the evening of Nov. 29, 1900, I was requested by Dr. Stidworthy to see the child with him, and found her to be well nourished, presenting all the appearances of having been possessed of a normal degree of health. The rectal temperature was 101 4/5, pulse 164, respiration hurried and embarrassed. It had been vomiting some, and no movements of the bowels had occurred for nearly 4 days, despite the fact that laxatives in generous doses had been administered repeatedly. The mother thought that the diaper had been wet about as usual.

Examination of the child's abdomen showed that it was immensely, and apparently uniformly, distended, the integument tightly stretched and glistening; the umbilicus protruded and was surrounded by an area of active hyperemia, as if the structures were the seat of an infective inflammation. This area was about two inches in diameter.

Palpation revealed the presence of a circumscribed collection of liquid in the abdomen, seemingly confined mostly to the right side. Percussion showed dulness over the whole abdominal area, except in the left hypochondriac, lumbar, and inguinal regions, backwards from about midway between the mammary and axillary lines.

I was under the impression that I had to deal with an accumulation of liquid within the remains of an imperfectly occluded urachus or vitello-intestinal duct, being inclined to the former opinion. The febrile condition present, as well as the area of inflammation about the umbilicus, led me to suspect the presence of an infection from some source. It did not seem that the intra-abdominal tension was sufficient to cause the inflammation mentioned. In order to determine the character of the fluid, I removed a small quantity by aspiration, through a point about one and one-half inches below the umbilicus, in the middle line. It was found to be a liquid of a light amber color. It occurred to me that possibly the vesical end of the urachus remained patent, and that this fluid was urine. I therefore emptied the bladder by means of a grooved director, not having on hand a catheter which could be passed.

The urine, as well as the liquid removed by aspiration, were then tested for albumin. The urine was found to contain none, while the aspirated liquid nearly solidified into a starchy-looking or colloid material on boiling, with nothing to indicate that the liquid was the product of renal excretion. It was now apparent that there was present one of the following conditions: An ovarian cyst; cystic kidney; cyst of the liver or pancreas; distention cyst of the gall-bladder, or distention of lesser peritoneal cavity, through closure of foramen of Winslow.

It was impossible to determine what intra-abdominal structure was giving rise to the cyst, yet I inclined to the belief that it had its origin from the kidney or ovary. The child's condition being precarious, and relief being necessary, it was decided to do a celiotomy and remove the cyst, if possible. Accordingly, the child was taken to the St. Joseph Mercy Hospital the following day, when, under chloroform anesthesia, the above views were carried out. The primary incision through the abdominal parieties was about one and one-half inches in length, and in the middle line, the upper end of the wound being about half an inch below the umbilicus. It was subsequently extended upward for nearly another inch. The primary opening in the abdominal parieties exposed the cyst wall, which was found to be adherent to the abdominal wall over an area of probably three or four inches in diameter about the umbilicus and to the right of it. This adhesion was separated, however, without much difficulty, but the cyst filled the abdominal cavity so thoroughly that its origin could not be determined.

The cyst was now opened between the grasp of two pair of hemostat forceps and partially emptied of its contents. Exploration of its surroundings showed its origin to be from the upper part of the abdominal cavity on the right side, and my diagnosis was that of a cystic kidney. The uterus and ovaries could be felt in their normal position. I re-introduced my finger into the sac to determine its exact point of attachment. The expanded portion of the kidney structure proper was found to lie under the liver, and its margins came so far forward that it quite covered the liver; I was, for a moment, in doubt as to the correctness of my diagnosis, fearing that I might be dealing with a cyst of the liver or a distended gall-bladder, and it was only after I had sought the liver and determined its normality that I was satisfied.

Thus, even after the abdomen was opened, the diagnosis of a cystic kidney was only problematic, and it was only after the other structures, from which the cyst might have arisen, were examined and found to be normal that the diagnosis could be verified.

As a detailed description of the steps in the operation are probably of little interest we will omit them, only stating that the time of the operation was fourteen minutes and that the child made a rapid recovery without any untoward symptoms and has since seemingly been enjoying the best of health.

Medical literature acquaints us with the fact that prenatal development of cystic kidney, while rare, is not an unknown condition. It at times reaches a degree of development which precludes a normal birth, evisceration having in some instances been found necessary before delivery could be accomplished. A large per cent. of children who survive birth are presumed to succumb early to the effects of pressure, as in the embarrassment of respiration induced by the limitation of diaphragmatic movement, or in the disturbance of the functions of the intra-abdominal viscera; while toxemia, resulting from inadequate renal function, is another potent factor in the early demise of these patients.

In cases where the size of the affected organ or organs, or the limitation of functionable renal structure is not extreme, the condition may not be incompatible with life, and it is believed that a small per cent. of such patients may reach adult years, or even old age. That is, providing that the condition remains latent and no intercurrent malady leads to an overworking of the remaining renal parenchyma.

It would appear that, while congenital cystic kidney may involve one organ, yet it is found to involve both organs in most instances, and associated with the condition there not infrequently may exist other malformations, namely, a horseshoe kidney or abnormally placed kidneys, or kidneys without pelves or ureters—hydrocephalus and hydrencephalus also existing. Cysts of the liver at times may co-exist. Instances are recorded of a mother having successively or interruptedly given birth to several children with cystic kidney.

Cystic kidney has had its cause ascribed to various factors by different investigators. Dr. Hektoen[1] concludes, after an exhaustive study of the subject, that the theories divide themselves into the following three sets: 1, retention; 2, cyst-adenomatous, and 3, teratological.

---

[1] Chicago Med. Record, September, 1892.

1. The theory of retention and dilatation, resulting in the formation of cysts, is based upon the study of a number of cases of cystic kidney in the old as well as in the newborn, in which there were actually demonstrated various causes of obstruction in the uriniferous tubules at the papillæ or elsewhere in their course. Mere mention of the various possible modes of obstruction suggested, but not demonstrated, will be enough; occlusion by the impaction of fibrinous casts, desquamated epithelium, blood, precipitated salts, etc. Virchow assumes a papillary atresia, or stenosis, due to a fetal inflammation, in order to explain the congenital cystic kidney. Complete obliteration, or absence of the pelvis, is mentioned by Thorn, Sutton, and others as capable of causing cystic kidney. Ewald, in briefly reviewing the literature on the etiology, states that many authors believe that chronic interstitial nephritis, with desquamation and impaction of epithelial cells or strangulation of the tubules by connective tissue, may cause cystic kidneys in some cases; the peculiarities, which would determine the instances in which total cystic degeneration and not merely small cortical cysts should take place, are not described.

2. The cyst-adenomatous theory is based upon the demonstration, in cases of cystic kidney, of the appearances characteristic of adenomata. In these cases the chronic interstitial changes are usually held to be secondary, although Sabourin concludes his study as follows: "Renal cysts in cirrhosis develop from tubules whose epithelium is reduced to an indifferent state; by fusion, cysts are formed, which merit the name of adenoma." Hommey, Lejars, Cornil et Brault, Brigidi, Sevin and Phillipson adopt the same view.

3. Theoretically, the kidney should be the organ of all others able to furnish instances of the teratoid origin of tumors from persistent embryonic rudiments, but few renal growths have been regarded from this point of view. S. G. Shattock concludes that the congenital cystic kidney is formed by a combination of the meso- and meta-nephros, the remnants of the Wolffian body developing into cysts scattered through the proper renal tissue; the tension upon the intertubular tissue by the enlarging cysts might cause the interstitial changes; the presence of urinary constituents in the cysts does not mean, according to Shattock, that they originate from the kidney proper, because the meso-nephros in the fishes and the amphibia perform the function of the permanent mammalian kidney. Bland Sutton adopts and advances this view enthusiastically. He says that the microscopical appearances of a congenital cystic kidney and of the meso-nephros at its fullest development, the sixth week, agree completely.

Dr. Hektoen's own conclusions are:

1. The common cystic kidney in the old is best explained as due to retention caused by a chronic interstitial inflammation of the pyramids, and the medullary rays especially, as well as of the labyrinthine structure of the cortex. The epithelial lining of the cysts is entirely passive and often absent. There is no epithelial proliferation and new cysts formation demonstrable. A congenital or adenomatous origin for the cysts can only be inferred and not demonstrated. The etiology of the chronic inflammation is obscure in many cases; in others it may be referred to an ascending pyelopapillitis from calculi or to the same causes that produce the ordinary chronic interstitial nephritis.

2. Cystic kidneys, presenting a proliferating epithelial lining, with evidences of new cyst formation by budding from the old cysts or from uriniferous tubules, are plainly instances of renal cyst-adenomata.

Reasoning by analogy from other organs in the body, occasionally the seat of cystic adenomata, it would be expected that this variety of cystic kidney would most frequently be unilateral.

3. Congenital cystic kidney, without any demonstrable cause for obstruction and urinary retention in the tubules and presenting the structure characteristic of the meso-nephros, as described by Shattock and Sutton, is most reasonably to be regarded as coming from misplaced meso-nephrotic remnants. To look upon all cystic kidneys as congenital cannot be considered proper in view of the instances cited of cysts developing directly as the result of compression of the tubules and the papillæ by fibrous tissue, and cystic adenoma of the kidney can occur at any time of life.

The etiology of the case which I have presented is in doubt, I having been unable to fix upon any definite factor for its production. However, I am of the opinion that its cause must have been an occluded ureter, or even an absence of it, for I have not been able to find it. If a ureter did exist and was subsequently occluded the cause and whether this condition developed prenatal or postnatal must remain an open question.

The points of interest which are presented by this case are the following:

1. It involved only one kidney, and the fact that it developed to such a degree without leading to serious disturbances till occasioned by its encroachment upon the gastro-intestinal tract, through pressure, was of interest. However, involvement of one kidney can not be considered remarkable if my conception of its production be correct, namely, an occlusion or absence of its ureter; for then it would be likely to involve but one kidney, and with one normal kidney the excretory functions of those structures were no doubt properly carried on by the healthy one, thus leaving the child's general condition normal, except for the disturbances from the pressure.

2. The difficulties in the way of arriving at anything but a problematic diagnosis prior to direct inspection of the growth, it seems to me, are quite insurmountable; and even inspection of the growth does not lead to a positive diagnosis, till all structures, from which a more or less similar condition might arise are examined as to their normality, and a diagnosis being thus arrived at by exclusion. An organ thus distended no longer possesses any recognizable characteristics of its former self.

3. The case is further illustrative of the capability of children to endure what may be considered capital operations, provided that precautions are exercised in reducing to a minimum the period of anesthesia and operation, as well as the loss of blood. As nearly as I am able to learn from records which I have, this is the youngest child that has survived a nephrectomy. Dr. Roswell Park,[2] some years ago, having done a nephrectomy for congenital cystic kidney upon a child aged 23 months, with resulting recovery. Up to that time this was the youngest child that had recovered. Since that time Rovsing[3] has operated upon a child 9 months old for congenital hydronephrosis, with recovery.

GONORRHEA IN BOYS.[*]

ABRAHAM L. WOLBARST, M.D.
ASSISTANT SURGEON, GOOD SAMARITAN DISPENSARY.
NEW YORK CITY.

Of late the number of cases of gonorrhea in boys has been so large in some quarters that it has attracted more than passing notice, both as to the cause of their occurrence and to their general behavior and treatment. Within the past two years, twenty-two cases have come under my supervision, in patients ranging in age from 18 months to 12 years.

For purposes of scientific accuracy, the secretions were stained by the Gram method, and examined for the Neisser gonococcus, and in each case, without a question of doubt, the specific germ was found. In addition to the evidence furnished by the microscope, the clinical symptoms were carefully noted, and, when combined with the microscopic testimony, left no room for doubt as to the true nature of the infection.

---

[2] Surgery by Am. Authors, vol. i, p. 432.

[3] International Text-Book of Surgery, vol. ii, p. 596.

[*] Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee of the Section: Drs. H. E. Tuley, Edwin Rosenthal and Samuel W. Kelley.

It is commonly maintained that the source of infection, in the majority of juvenile cases, can be traced to the using of soiled linen, or infected water-closet seats—and to infected catheters in hospital cases. A most careful inquiry into the prevailing social conditions, however, and the histories of the cases that have come under my observation, lead to the conclusion that there are strong reasons for assuming that in children, boys as well as girls, the usual mode of infection is responsible for the disease, in more cases than we are accustomed to believe. Especially is this true in districts where the poor are crowded together in tenement houses, where the children are alive to the enjoyments of sexual gratification at an extremely early age, and where the dark cellars and water-closets and the roofs offer splendid opportunities, first for experiment, later for enjoyment.

It is not at all uncommon to learn that boys and girls, who have not yet reached the age of puberty, indulge in sexual gratification. Contact with older children, who have had their curiosity satisfied by personal experience, stimulates the sexual appetite in these children of the tenement and so-called "red-light" districts, at an age when impressions are easily made and habits contracted. The result is an excessive desire for the gratification of their precociously developed appetite, which, as can be easily shown, is not difficult to satisfy.

In my study of this subject there have been observed three cases of gonorrheal urethritis, in boys aged respectively 4, 10 and 12 years, which were acquired in the usual manner, from girls ranging between 10 and 12 years of age. In each case, according to the story told by the victim, the girl made the first advances, and in one case, that of the 4-year-old boy, the act was consummated in the form of an assault, by a girl 12 years old, in which the child was threatened with injury unless he performed his part.

In about one-half of the cases, there was no history of infection in this manner, but the cause was traced to the child sleeping in the same bed with a parent, brother or sister, who were found to be suffering from gonorrhea. Here again the cramped quarters of the tenement dwellers, with their lack of proper sleeping accommodations and their promiscuous intermingling of the sexes, may be held responsible, in a large measure, for the causation of this disease in young boys.

Then there were a number of cases that were admittedly produced by acts of pederasty. This mode of sexual gratification, among these highly stimulated children, is not at all uncommon. The roofs and water-closets of tenement houses, in the spring and summer especially, offer public exhibitions of this kind, to those who are alive to the existence of the practice.

In districts where prostitutes live in tenement houses and mingle with young children, gonorrhea may develop in boys as the result of an attempt on the part of the prostitute to rid herself of the disease by cohabiting with a male "virgin." This practice is induced by a superstition brought to this country from some parts of Europe. It promises those suffering from gonorrhea, of either sex, who cohabit with a virgin of the opposite sex, that they will thereby rid themselves of the disease.

Whatever the cause of the infection may be, the period of incubation and the general character of the disease do not differ from these manifestations in the adult. In from four to seven—sometimes ten or twelve—days after the infection, the subjective symptoms, pain and burning sensations on micturition, frequent desire to micturate, and sometimes almost complete retention, manifest themselves. A day or two later the meatus becomes red, swollen and puffy, and presents the typical "angry" appearance that constitutes an almost positive landmark in making the diagnosis of gonorrheal urethritis. The discharge is usually profuse from the beginning, not differing in appearance or consistency from that seen in the adult.

The pain which some of these children suffer is often out of all proportion to the clinical picture presented; but this hypersensitiveness is often found to be coincident with the presence of a contracted meatus or a tight prepuce, which probably acts as a dam to the secretions and by preventing proper drainage of the urethral canal, causes retention, and a consequent increase in the inflammatory products. Other children, on the other hand, suffer very little pain, and would probably not be brought to the surgeon for treatment but for the presence of the redness and swelling at the meatus, and the discharge.

Right here the importance and great value of circumcision may be pointed out. The redundant foreskin very materially interferes with the cleansing of the parts, and helps to complicate the condition of urethritis *per se*, with the additional balanitis and gland infections that are so often also found in the uncircumcised adult. Every case of gonorrheal urethritis in uncircumcised children offers a most eloquent plea for the circumcision of all male infants, when the possibility of future gonorrheal infection is considered. Both as a prophylactic measure against infection of the urethra by retained secretions within the prepuce, and as an invaluable aid in the treatment of urethritis should it appear, the operation of circumcision in infants deserves a position in the routine management of male infants after childbirth, second only to the care of the eyes and of the umbilical cord.

When the disease has lasted several days complications similar to those in the adult may appear. Posterior urethritis, and even prostatitis and epididymitis, has occurred in these cases; and in one case, that of a child 19 months old, with a very small meatus, there was an almost total inability to pass the urine, which condition was relieved only by the introduction of a fine woven catheter.

If the prostate is involved it becomes swollen and highly sensitive, causing exquisite pain when attempts are made to move the bowels. The epididymis, when involved, is also swollen and exquisitely tender to the touch.

In general, it may be said that the disease presents the same symptoms and complications as are seen in the adult, and it is interesting to note that the duration of the disease, from four to six weeks, is also about the same as in the adult.

The prognosis, as to complete recovery, seems to be better than in the adult. In young boys, there does not seem to be that tendency toward the continuance of the disease in the chronic form, and strictures are not so likely to follow as in the adult. I have never seen rheumatism develop in these cases. Recovery is complete and the inflammation leaves slight, if any, traces behind it.

Under the subject of treatment, the question of prophylaxis must be considered. The occurrence of gonorrhea in boys and infants would be one of the rarest of diseases, if proper care were taken by the parents and associates of these children. There is a strong element of criminality present when young children are permitted to become infected with a disease that is acquired only through actual contact with the infected discharges, and in a well-regulated society there should be a severe penalty for that criminal negligence or viciousness that results in the production of gonorrhea in children. If parents, or relatives, or playmates are suffering from the disease in any of its forms, the most stringent precautions should be taken to prevent healthy children from contamination. The physician, especially when practicing among the poor, should see to it that healthy children are not permitted to sleep in the same bed with those who are suffering from gonorrhea. He should also take care that the discharges be destroyed before infecting others, and that, immediately on the appearance of any of the symptoms of an infection, the patient be warned of the dangers that lurk in the urethral discharge, and be instructed in the measures to be taken to prevent the infection of other members of the family.

The primary requisite for the proper treatment of the disease is cleanliness, even carried up to the surgical degree. The cleansing of the parts will not only aid in bringing about a cure, but will also prevent the occurrence of some of the painful complications that would otherwise follow. If the child has been circumcised, the problem of keeping the parts clean is not a difficult one. Warm water, applied at intervals of three or four hours during the day, will keep the meatus and the surrounding tissues clean. A solution of boric acid or a weak solution of bichlorid of mercury may also be used for this purpose. If the prepuce be present, great care must be used to remove the secretions by constant cleansing with any of the above mentioned solutions. If the prepuce be a tight one and not easily drawn back over the glans, the solution may be slowly injected, by means of a small glass syringe, between the prepuce and the glans. This must be done at frequent intervals in order that the accumulated secretions may be removed. The development of phimosis will also be averted, if due attention is paid to this subject.

For the urethritis itself, the medicinal treatment will largely depend upon the extent and character of the inflammation. If the anterior portion alone of the urethra be involved, the injection of a one-half per cent. solution of protargol, three times daily, retaining it about five minutes each time, will often prove wonderfully effective in stopping the pain and removing the discharge. In three of my cases, a complete cessation of the pain and the discharge followed the second injection of this solution.

Unfortunately, however, these excellent results do not follow in every case. In spite of this treatment, or perhaps because of it, the inflammation often extends to the posterior portion of the urethra, bringing with it all the symptoms of posterior urethritis. In conditions like this, the injections into the anterior urethra are not only useless, but sometimes positively harmful. Irrigation of the urethral tract, with a mild solution of potassium permanganate (1-6000) or of the Thiersch solution, will prove of decided benefit. This is best accomplished, either by the use of the catheter with the eye in the posterior portion of the urethra, or by the small glass syringe. With the latter, the fluid can be slowly and gently injected directly into the bladder, without causing pain or irritation. When the bladder is fairly well filled, the irrigating fluid is permitted to flow out and the process repeated. The injection of weak solutions of protargol—1 to 400—into the bladder in this manner will also prove of value in some cases.

For internal administration, the pure oil of wintergreen, in doses of 5 to 10 minims, in milk or water, three times daily, will be found valuable in some cases. In others, an alkaline mixture, containing potassium bicarbonate and tincture of hyoscyamus, will bring relief from the pain and tenesmus.

When complications arise, they must receive appropriate attention. Epididymitis is best treated by the application of guaiacol ointment, 10 per cent. strength. Hot poultices also bring relief in some cases. When the prostate is inflamed and extremely painful, rectal irrigations of hot water will bring grateful relief. At night, suppositories containing a small amount of morphin and belladonna may be employed to relieve the intense pain and tenesmus. The bowels must be kept open by the use of irrigations or laxatives, and rest in bed should be enforced.

A dressing should be applied to the meatus and so applied that it can not fall off or be removed by the patient. Small sized "gonorrhea bags" may be used with excellent effect, in the prevention of further contamination. It is needless to point out the importance of preventing an infection of the eyes from the urethral discharge. In children, moreover, who can not always be made to understand, especial pains should be taken to prevent this. Strict attention to cleanliness and the use of a "gonorrhea bag" will positively guard against the occurrence of eye inflammation.

187 Henry Street.

DISCUSSION.

Dr. Edwin Rosenthal, Philadelphia—I have seen gonorrhea in children so very frequently. With regard to the superstition of prostitutes that they can get rid of the disease by giving it to a virgin, I would say that this prevails very widely and often accounts for attacks of rape. At one time I saw a whole troop of boys who had contracted gonorrhea in this way, and I only checked it by hunting up the guilty prostitute, one "Rachel" by name. The mode of infection was various. The proof of the crime can be easily established by microscopic examination of the discharge, both from the guilty person and the one infected. Within the last twenty years there has grown up in the larger cities a sort of system of tenement houses in which two or more families live in one room, separated perhaps only by a chalk line. I am disposed to be a little skeptical regarding the dissemination of the disease by infection from dirty water-closets.

Dr. Clifton Scott, Des Moines—I do not think this is confined to the tenement houses. There is great need for widespread information among the very best classes of society. No one holds woman in higher respect than I, but it is a most pernicious doctrine which is promulgated in women's clubs, that men are naturally vicious and women are naturally pure, and that every prostitute is the victim of man's duplicity. The people at large should understand that there are vicious women as well as vicious men, who have been vicious from their youth up. I have seen a few of these cases, and I know that a number of them originate from servant girls who seduce boys left in their charge or allowed to sleep with them.

Dr. A. C. Cotton, Chicago—I believe this is a subject of unusual interest to those who are family advisers. The ignorance of the laity on these subjects, which are considered a little too delicate to discuss, is quite astonishing. I have been the city physician in Chicago for two terms of four years. One of the duties of that office is to look after the police stations, the bridewell, and, in fact, any one for whom the city assumes even temporary responsibility. In cases of rape and alleged assault the city physician is naturally the first one called in by the prosecuting attorney to see if there is any medical evidence. It is astonishing what a large number of cases of alleged assault on little girls there are. These cases rarely come to trial. I have been surprised at the large number of cases of gonorrhea among such little girls. As city physician I learned of one source of gonorrheal infection, i. e., the practice of men "playing" with the genitals of little girls, though not committing rape. This happens even in children so young that they do not know what is being done to them. I have had many cases to show that little boys go through the motions of copulating with the assistance of an older female. I recall a string of little girls coming to my clinic suffering from gonorrhea. A search of the records indicated that they all came from a certain locality, although these children represented quite a variety of nationalities. A week later my assistant brought to me a boy of 10 years who had been infecting these ten or twelve little girls.

Dr. J. C. Cook, Chicago—I was very glad to hear the paper, and yet it seemed to me to be lacking in scientific knowledge; for the time has arrived when we should know whether it is possible to transmit the gonococcus from fabrics to human beings. It is trying to our credulity to find a 4-year-old daughter and a 35-year-old father having gonorrhea at the same time with no other source of infection to the daughter other than the father, and yet I have observed this in a family of educated and refined people. I am glad to hear restated that it is possible to contract the disease in a water-closet. The superstition about getting rid of gonorrhea is a very prevalent one among the colored people of the South. I believe with Dr. Scott that there are many vicious men, and some vicious women, but, according to my observations, men are greater distributers of gonorrhea than women; because in dispensary work by far the largest number of cases of gonorrhea occur among females. It must be admitted that in many instances the male is the aggressor.

PREVENTION OF TUBERCULOSIS IN BABES BORN OF TUBERCULOUS PARENTS.*

CLIFTON SCOTT, M.D.
DES MOINES, IOWA.

In the presentation of this subject, I desire to present two cases and from them draw my conclusions and upon them base my arguments.

Case 1.—Mrs. A. H., a young woman, married at 19 years of age, had suffered with chronic pulmonary tuberculosis for five years previous, the existence of which, she and her mother denied. During the first two years of her married life she had frequent mild attacks of hemoptysis. She continually consulted her old, family physician, a homeopath, for these troubles, until Oct. 15, 1896, when she had a severe hemorrhage and I was called in haste. By putting her in bed and applying ice to the chest, the hemorrhage was controlled. I was then invited to take charge of the case.

I found a pulse of 96, temperature of 101, some moist rales in the lungs, quite marked emaciation; cough was not serious, except a paroxysm in the morning; there were no night sweats, and an examination of the first two specimens of sputum revealed no bacilli; in a third specimen, however, about fifteen or twenty to the field were found. I put her on hypophosphites with iron, quinin and strychnia; gave her liquid peptonoids with creosote, and recommended a liberal diet with a glass of cream to drink at each meal, with outdoor exercise and by arranging the changes in this treatment, she improved, gaining some ten pounds in weight. The cough diminished and the bacilli disappeared; no more hemorrhage occurred. She remained under my care for six months, when she ceased visiting me and I concluded that she thought she had discovered the method of treatment I was using and that she could carry it out herself.

About six months later her husband called upon me and wanted a prescription for indigestion, saying that she was nauseated and vomiting, and that she thought the medicine had disturbed her stomach. I inquired as to the possible existence of pregnancy, which he denied. I gave her a gastric sedative and heard nothing more for four months, when he announced that she was five or six months pregnant and that she was greatly alarmed, lest she might not be able to live through the ordeal. I advised him how to reassure her and saw nothing of her for two months, at which time she applied to me for a sore throat. She was now eight months pregnant and had developed laryngeal tuberculosis. There was marked hoarseness, almost complete aphonia. I applied an antiseptic spray and an alleviating treatment, and at term she was delivered of a girl baby, weighing five pounds. The child had an imperforate anus, which I corrected.

I had the child taken to an aunt and fed on modified cow's milk, and prevented communication between it and the mother. The mother was able to sit up and walk slowly about the house after a period of about 2 months. The laryngeal trouble had increased, the general emaciation of the body progressed from this time on and she died when the baby was about five months old. The child is now three years old and is a picture of health and vigor. It is well developed, having exhibited no symptoms of infection or hereditary effect.

Case 2.—A young woman, married at 20 years of age, claimed to have enjoyed previous good health. Father died of tuberculosis several years before. Marriage occurred in the second week of May, 1899. She claimed to have enjoyed good health during pregnancy. She had worked hard washing woodwork and cleaning a house into which they moved about February 10, and about March 1, I was engaged to attend her in confinement. I found a pulse of about 80, with no albumin in the urine. She claimed to feel perfectly well. I afterwards learned that she misrepresented her general condition of health. Her lungs were not examined.

She was confined March 14; mother and babe did well the first week after confinement and I did not see them again for three weeks. Twenty-five days after confinement, the mother rode three miles into the city in a street car and did some shopping. Two days after this she walked five blocks and read a paper at a literary club. The child had been nursed during this time, and twenty-eight days after confinement I was called to see her. I found her walking about the house, with a pulse of 120 and temperature, 103. I ordered her to bed and notified her mother, who came to attend her. An examination of the lungs exhibited some rales in the left lung. The range of the temperature, and character of the sputum did not indicate pneumonia. The progress of the condition for the next three days excluded bronchitis.

Dr. Eli Grimes was called in consultation; I had collected some sputum, which was stained and examined by Dr. Grimes and myself. The fields exhibited an immense number of tubercle bacilli. A diagnosis of acute tuberculosis was made. Dr. J. T. Priestly was called in consultation. The babe was immediately put upon modified cow's milk. The mother's condition progressed rapidly to an end, she dying just sixteen weeks after her confinement, and the child having nursed during the first five weeks after birth. Immediately after weaning, it began to exhibit loss of weight, palor and cough, also rales could be detected in the lungs. It passed through a well marked history of acute tuberculosis, dying one week after the mother.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee of the Section: Drs. H. E. Tuley, Edwin Rosenthal and Samuel W. Kelley.

In discussing these two cases, what evidence have we that the second one suffered from hereditary tuberculosis any more than should have been expected in the first? To be sure, in one case, tuberculosis was chronic in the mother, in the other, acute. But in the first case, the child was not allowed to nurse and in the second, because tuberculosis had not been diagnosed, it was allowed to nurse and it seems possible that the infection in the second case came from the mother's milk or possibly from kisses, caresses and other contact. I do not think that infection of the child in fetal life, through membranes of the placenta, can be positively denied, but that its occurrence is very infrequent is clearly proven.

The principal point, for which I wish to plead, is, that the old stereotype methods of visiting the mother a few weeks before confinement, securing a specimen of her urine and testing it for albumin is not a sufficient precaution for the safety of the child. These preliminary examinations, made at safe intervals during the last two months of pregnancy, should include a general physical examination and careful search for tubercle bacilli; many cases will thus be found, and our knowledge of the existence of tuberculosis, in otherwise unsuspected cases, will not only enable us to guard better the mother's condition, but will save many babes from infection, through guarding against the use of the mother's milk and infection by contact. If this method be carried out rigidly and the people educated to appreciate its importance and value, many children of tubercular parents can be saved from infection.

DISCUSSION.

DR. EDWIN ROSENTHAL, Philadelphia—I have at the present time under my care an exactly similar case. A woman with tuberculosis gave birth to a child one year ago. The usual bacteriological tests had been made to insure the correctness of the diagnosis. From the moment that this little girl was born it was not allowed to take any of the mother's breast milk. The child was fed on a home modification of cow's milk, and has not shown any evidence of tuberculosis. This is only one of many cases, yet I believe these are the exceptional ones. I believe we should use our influence to advise against marriage of a woman known to be tuberculous. I am convinced that this would greatly diminish the number of cases of tuberculosis.

DR. COLLINS H. JOHNSTON, Grand Rapids, Mich.—This paper brings up several subjects of interest. I think we can learn something from the experience of the veterinarians. The Wisconsin Agricultural Experiment Station has adopted the Stockholm plan of treating tuberculous cows. When an animal reacts to the tuberculin test it is not slaughtered, if in the early days of tuberculosis; nor is the milk of such animals used for any purpose. But experience has shown that these cows can be used for breeding purposes, and that if their calves are removed from the infected atmosphere, placed under good hygienic surroundings and fed on milk free from tubercle bacilli, they will not show any taint of disease. I think most of us must have observed the same thing in the human. Osler, as I have said, insists that there are only twenty cases of congenital tuberculosis in the literature. Dr. Scott's two cases were evidently the result of infection of the mother by her sputum or tuberculous milk. It has been proven, both experimentally and otherwise, in this country and in England, that tubercle bacilli exist in milk of tuberculous cows, and also in the cream and in the butter of milk from tuberculous animals. There can be no question, therefore, that tuberculous mothers can infect their offspring by nursing them. Another cause of tuberculosis in infants is the poor aliment frequently given children in the first year of their lives, whereby they are rendered less resistant to the germs of disease. The great mass of the profession pay very little attention to the question of infant feeding. It is one of the most important problems before the profession to-day.

DR. F. X. WALLS, Chicago—I should like to call attention to a specimen in the pathological exhibit here by Dr. Fütterer. The case is that of a child of a year old who died from localized miliary tuberculosis. In that case there was a primary tuberculosis of the intestine, with an extension of the tuberculosis to the mesenteric and the mediastinal lymph glands. The specimen has been so treated as to preserve the fresh appearance, and it shows the rupture of a caseous lymph node into a branch of the pulmonary vein, and from that a dissemination of miliary tubercles to the remainder of the lung This emphasizes very well the care which we should take in the management of the babies of mothers who have tuberculosis in evolution. The mother of this infant had been ill with tuberculosis, and becoming insane had been sent to an asylum. It is very probable that tuberculosis is rarely acquired through the milk of a nursing mother, because tubercle bacilli are not eliminated through the normal mammary gland, but only through a tubercular gland. The point made in the paper about keeping these little ones as far as possible from all sources of infection is very well taken, and should be borne in mind.

DR. J. NOER, Stoughton, Wis.—A wrong inference may be drawn from the investigations of the Experimental Station in Wisconsin. I live near that station and am familiar with the work. It is now six or seven years since the first investigation was made. It was found on testing 27 or 30 cows at the station with tuberculin that 86 per cent. of them were infected with tuberculosis. These were all, as I recollect, slaughtered, partly because of the danger of contagion and partly to demonstrate postmortem the diagnostic reliability of the Koch tuberculin test, then new, in incipient cases presenting no clinical evidences of disease. It is true that isolation and quarantine rather than the slaughter of tuberculous cattle has since been the practice in Wisconsin. It has been shown at the Wisconsin Agricultural Station that healthy calves could be raised from tuberculous cows, that is, provided that the calf was at once isolated from the mother and carefully protected from tubercular infection, through milk, drinking water, feeding trough or the stable. Now, as regards the danger of spreading tuberculosis in man through the use of milk and butter from cows having incipient or early tuberculosis, we have, I think, very much exaggerated the danger of transmission. I do not wish to be understood as advocating the use of milk from tuberculous cows. I would like to have all milk cows tested with tuberculin and those showing reaction excluded from the herd supplying milk for human use. This would be a reasonable precaution pending further investigation. There is, however, as yet no evidence to show that bovine tuberculosis is transmissible to man. Is there a person here who can report a case of such transmission? When it was shown that nearly all the cows at the Wisconsin Agricultural Station were tuberculous, a great deal of anxiety was felt by the families at the station, who had been using the milk from these cows for their children. No case of transmission has, however, been traced.

The early studies of the Russian student Rabinowitsch indicate that tubercle bacilli are very exceptionally present in market butter. Adami, of Montreal, has shown that only a fraction of 1 per cent. of Canadian cattle are tuberculous, yet human tuberculosis is fully as prevalent in Canada as it is in the Eastern States, where bovine tuberculosis exists in from 20 to 40 per cent. of the cattle tested. It is evident that we need more light on this subject before we formulate any conclusions that are worthy of serious consideration.

Dr. C. H. Johnston—I do not say that the milk of every tuberculous cow shows tubercle bacilli, because this is not the case, but it has been proven repeatedly that the milk of tuberculous cows may contain tubercle bacilli, even though there is no demonstrable tubercular lesion of the udder. The detection of a tuberculous udder in its incipiency is difficult even for an expert; hence, it may often happen that milk contains tubercle bacilli though no tubercular lesion can be demonstrated in the udder.

Dr. I. A. Abt, Chicago—I wish to enter a protest against the idea that there are only a limited number of cases of tuberculosis which are congenital in origin. There is no doubt in my own mind that the number of cases of congenital tuberculosis which occurs in young infants must far exceed the origin in any other way. When we think that children, three months, six months or a year old often die of tuberculosis, although they have been under the best possible hygiene, it seems to me reasonable to suppose that these cases are of congenital origin. The only proof of the hereditary origin of the disease would be the demonstration of tubercle bacilli in the placenta or in the endometrium.

Dr. Edwin Rosenthal—Dr. W. P. Northrup presented a paper on "Tuberculosis in Children" before the Philadelphia Pediatric Society, and showed that the very inception of tuberculosis in children is through the lymph nodes primarily.

Dr. Noer—I should like to know if any one present can produce a single case in which tuberculosis has been transmitted from the cow to a child. I am not aware that it has been demonstrated that bovine and human tuberculosis are the same.

Dr. J. C. Cook, Chicago—I have under observation a lady sick with tuberculosis. It began as a cervical tuberculosis. A most minute inquiry as to the source of infection leaves very little doubt about its having arisen from a pet monkey. This animal had been sent away two years previously because it had tuberculosis.

Dr. C. F. Wahrer, Fort Madison, Iowa—It would take a person with much fortitude to feed his children on the milk from a tuberculous cow. I wish to call attention to the specimens exhibited here by the Army Medical Museum. In this collection are several very beautiful ones of tubercular lesions of the udders. I advised a tuberculous mother not to nurse her infant, but to feed it on cow's milk. The cow presented every appearance of being healthy. The child died a few months later, and was found to be tuberculous, showing the importance of examining the animal before accepting the milk. Even if transmission of bovine tubercle to children can not be proved to take place directly, it were surely a good precaution not to feed a child milk from a tuberculous cow.

Dr. E. F. Brush, Mount Vernon, N. Y.—Some years ago I had a cow suffering from acute miliary tuberculosis. I took the animal to another part of the farm and killed her. I shut up 24 laying hens and a rooster and fed them with tubercular masses from the lungs and intestine of this cow. I selected for this experiment hens because their body temperature is high, about 108 F. Some of them developed tuberculosis within eight days after beginning the feeding experiment. All of them died within five or six weeks from the time I began the experiment. I took the last 24 eggs laid by these hens and set them under healthy hens. All of these eggs developed a chick, but every one of them was dead. I took four of the dead chicks down to the Carnegie Laboratory, but through some mistake or carelessness, they were not examined nor reported upon. I purpose to repeat the experiment.

In regard to the transmission of tuberculosis from cattle to children, I would say that at one time I found a cow with acute miliary tuberculosis and killed her. There was a large tubercular encysted mass in the cow's mediastinal space, which she had probably had for years. The gentleman who owned this cow had brought up seven children on her milk, and although these children must have been fed on tuberculous milk, they remained healthy and did not develop tuberculosis. There must be something else besides the mere presence of tubercle bacilli to start the tubercular disease. The additional element, I think, is an elevation of temperature. I think tuberculin is doing an immense amount of harm, and that its use is entirely unnecessary as a means of diagnosis. I know of a herd that is kept tuberculous by testing the animals with tuberculin. It is a very easy matter to make a diagnosis of tuberculosis in a cow when the disease has advanced far enough to do any harm.

Dr. Clifton Scott, in reply—I wish to thank the members for this interesting discussion. I was much pleased to hear Dr. Abt point out what must be the conditions to have congenital tuberculosis. I do not believe that congenital tuberculosis is so frequent as Dr. Abt seemed to indicate, but the fact that a cow may be tuberculous and not give tuberculous milk unless there is a lesion of the udder points strongly to the fact that the mother may have tuberculosis and yet if the endometrium is not tuberculous during pregnancy there is not much probability of infecting her child. I have always felt a little guilty about not having discovered that the mother in my case was tuberculous before her confinement, for I might possibly have been able to save that child. I did not know that the mother was tuberculous, yet I think if I had been given the opportunity to give the case sufficient attention before confinement I should have discovered this fact.

THE ETIOLOGY OF PARETIC DEMENTIA.*

FRANK P. NORBURY, M.D.
JACKSONVILLE, ILL.

The lesion of paretic dementia is that of a diffuse parenchymatous atrophy of the nerve cells and part, at least, of the neuroglia. This process is essentially chronic and involves more or less the whole of the cortex, even extending to the basal ganglia and the cord. The well-known vascular changes start in the minute arterioles and in a slow but progressive manner involve the nutrition of the cells thereby causing degeneration of the neurons and neuroglia. The cortical substance undergoes atrophic changes and the lymph spaces dilate or widen; the lymph currents are interfered with —they are laden with debris—and ultimately the combined processes produce profound degenerative changes.

The question of the cause of this now well-recognized degeneration is seemingly in dispute, but I dare say that we all feel that there should be but little controversy over this question, when in the light of the accumulated knowledge of to-day we find syphilis paramount as an etiological factor. In fact, it is the one factor—the primary factor—and with Dana we can say "if there were no syphilis there would be no paretic dementia. Other authorities endorse this view, notably Mongeri,[1] who says "syphilis is necessary for the disease to develop; it is the factor which prepares the soil, while alcohol and heredity merely aid in its development." "Without syphilis, congenital or acquired, it is impossible to have general paralysis." These statements do not seem to lack verification when we consider the inoculation experiments, detailed by Krafft-Ebing, where in a series of cases, typical examples of paresis, in which by strict inquiry and examination the previous existence of syphilis could not be ascertained and in the face of this negative history, the patients were inoculated with virulent specific virus and yet after the allotted time for infection no evidences of syphilitic infection occurred. Not a sign or a symptom appeared, thus confirming at least by negative evidence that previous infection had occurred and serves to impress us in the belief of the existence of latent syphilis in all cases of paretic dementia.

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

[1] Am. Year-Book, 1901.

Paretic dementia certainly, then, has for a background syphilis. It is not in truth a syphilitic disease *per se*, but a para-syphilitic disease, due to the effects of the syphilitic poison. That is not a syphlitic disease, we know, by the therapeutic test. It is not amenable to anti-syphilitic treatment, in fact such treatment is utterly useless, although many practitioners persist in giving it a trial. The luetic poison of syphilis acts as do intoxicants—it is a toxin—there is auto-intoxication interference with nutrition and after its very early and prodromal stage causes a degenerative change of the nerve elements. There are no syphilitic lesions and in my experience the evidences of syphilis are, as a rule, seldom marked. In the beginning, the vascular stage of paresis, the lesions are those due to a toxin. There are none of the common lesions of syphilis such as noted in cerebral syphilis, viz., gummata and endarteritis. The toxin acts upon neural tissues to produce the morbid alterations, which, while at first they may be purely functional, ultimately become well-defined organic changes.

In the etiological study of about two hundred cases of paretic dementia, I found the history of syphilis in fully 60 per cent., which, in view of the fact that the history of many of these cases is meager, is yet conclusive as to syphilis in the general run of such cases. Inasmuch as it is impossible to confirm by inoculation tests the cases in dispute, we are disposed to believe that possibly many more of these cases are syphilitic and lack but the opportunity to establish the proof. I have sometimes thought that while we regard syphilis as the primary etiological factor, there may be other contributing factors, inasmuch as in my experience I have had several cases that, seemingly at least, have been pronounced or developed after some one of the infectious fevers. Thus suggesting the thought that these fevers assisted in some way in the development of the disease.

The following case, recently under my care, is an illustration:

A ranchman, with syphilitic history, who after successful years in business was induced to go to the Transvaal. Here he contracted pernicious malarial fever, from which he suffered greatly while in Pretoria. He was sent home and while en route it was noticed that he was acting queerly, developed mental peculiarities which in view of subsequent history were indicative of general paralysis. I say in view of subsequent history, simply to enforce what I said in a paper before the Illinois State Medical Society in 1892, that the early symptoms, the functional stage. of paretic dementia is not recognized from other forms of insanity by the attending physician and in consequence the prodromal stage is passed before the alienist meets the case. The stage when if any help is to be had for this disease it is to be given at this time. This patient developed into a typical case of paretic dementia and died after two years from the first appearance of the disease.

Another case first showed recognizable mental peculiarities during convalescence from typhoid fever, the mental symptoms being attributed to a post-febrile psychosis. This case was of the fulminating type, rapid in its course and terminated by death in three years. Another case with negative syphilitic history, during convalescence from an acute articular rheumatism, was noticed by his family to have certain marked changes in his disposition. They thought nothing of it after the family physician assured them "it would pass away." But no, the case progressed, and rapidly too, resulting in death in about two years and a half after the attack of rheumatism.

I am sure that one swallow does not make a summer, but here are three cases coming under my observation, wherein after acute infectious fevers there has followed paretic dementia. Syphilis appears in the history of two—arthritic diathesis and rheumatism in one, all of whom had severe illness, just prior to appearance, at least of recognizable symptoms of paresis, and from such coincidences I am inclined to believe these diseases were contributing etiological factors.

The hereditary history of most of my cases shows that the neuropathic diathesis is the soil upon which this disease grows. Berkley says: "Heredity and syphilis are the most potent etiological factors." In his pathological findings he notes "microscopical evidences of irregular construction and anomalies in the cortical cells." From these facts we infer that there is a certain instability of the nervous elements which contributes to the susceptibility of an individual to the luetic poison of syphilis; that there is in fact selective action of this toxin upon neural tissue under certain conditions. This opens up that great question of immunity and susceptibility which is not to be discussed here. However, experience among the insane, including the cases of paretic dementia, leads all clinicians to form an opinion as to the family peculiarities, the hereditary considerations necessary in studying his cases, when he comes in contact with other members of the family than the patient himself. From this observation, however cursory, he draws the practical conclusion that heredity is certainly a factor and a potent one in paretic dementia.

Alcoholism is a contributing factor, but not of the importance ascribed to it by some. The brain lesions of the alcoholic are not those of paretic dementia and they simply are contributing degenerative conditions, which directly interfere with brain nutrition. I am told that in Colorado, alcoholism is usually a part of the history of such cases, but whether they are mere coincidences or not remains to be seen. I am inclined to believe alcoholism is coincidental in most all cases. I very much question cold, exposure and traumatism as being etiological factors; they can not cause such grave pathological changes. I conclude that:

1. Syphilis is the factor in chief which causes paretic dementia.
2. Infectious fevers with their toxic influences are contributing etiological factors.
3. Heredity is a potent factor.

DISCUSSION.

Dr. Harold N. Moyer, Chicago—I do not know that I have any exception to take to some things stated by the essayist, but I certainly do not agree to all of the three deductions with which he closes his paper. I think we are not prepared to make the claim that paretic dementia is a para-syphilitic disease, nor do I think the author makes that claim. I know that in from 60 to 80 per cent. of cases of paretic dementia we get a syphilitic history, but does that justify us in saying that all the cases are syphilitic? If so, we must assume that because in a considerable proportion of cases syphilis is the etiological factor, the rest must have had latent syphilis which we were not able to recognize. I believe that such a doctrine is fraught with considerable error, because it is not justified by facts.

The hereditary influence in paretic dementia is very limited and is usually confined to cases of impure paretic dementia, those where we have it with a background of paranoia.

There is one question in relation to paretic dementia which is of considerable importance, namely, the racial distribution of the disease. Among the natives of Hawaii, syphilis is a household disease; there is scarcely a native who has not been syphilized. Still, not a single case of paretic dementia has been recognized. There are other races among whom syphilis is very common, while paretic dementia is rare. The converse is also true. Recent statistics have shown that while syphilis is rare among the Hebrews in London, as compared with other Caucasians, paretic dementia is relatively quite common.

Dr. E. G. Carpenter, Columbus, Ohio—While my own experience is in accord with the general consensus of opinion that syphilis plays an important part as an etiological factor in paresis, still cases have come under my observation in which it was impossible to obtain any history or evidence of syphilitic lesions, and it is my belief that it is possible for paresis to be caused by factors other than syphilis. I believe that in the causation of many cases of paretic dementia, stress is an important factor. This, together with exhaustion from sexual excesses and the abuse of alcoholic stimulants, is sufficient to produce paresis in one having a neuropathic constitution. I think that in all cases we should be very cautious in asserting that a certain condition is due to syphilis, as there are circumstances where such a statement might do some people much harm; for example, in cases where the question of a pension and insurance is involved.

Dr. Richard Dewey, Wauwatosa, Wis.—I have seen at least six or eight cases of paretic dementia in which—as far as you can exclude anything—syphilis could be excluded, unless hereditary syphilis would be assumed. That assumption, however, can not be accepted without the existence of certain data upon which to base it. The statement made by Dr. Moyer, with reference to the racial distribution of syphilis and paretic dementia, leads me to refer to a confirmatory article bearing upon this subject which recently came under my observation. In this article the statement was made that while syphilis was very common in Mohammedan countries, paretic dementia was much rarer there than in non-Mohammedan countries, especially in Christian countries.

Dr. Sydney Kuh, Chicago—It seems to me that the question as to the etiology of paretic dementia, so far as anything definite can be said about it to-day, may be summed up as follows: That there is much evidence to show that syphilis is by far the most important etiological factor, both in paralytic dementia and in that other disease which is so closely allied to it, tabes. Whether or not syphilis is the only etiological factor it is impossible to say. The argument that in countries where syphilis is common, paretic dementia and tabes are very rare would prove nothing either in favor of or against the theory that there is some connection between the two conditions. The character of syphilis has changed completely within the last four centuries. When syphilis was first described, it had the character of an acute infectious disease which in a relatively short period terminated fatally. It is very possible that in certain countries the character of syphilis has assumed a different form from that which it has assumed with us. It seems that certain types of syphilis are particularly prone to produce grave degenerative changes in the nervous system of certain individuals. Instances have been recorded where two or three men were infected with syphilis by the same woman at practically the same time, and all developed the symptoms of tabes.

Dr. Edward E. Mayer, Pittsburg—While it is a well-known fact that most cases of paretic dementia give a syphilitic history, it seems to me that we must place the relationship between these two diseases upon a more scientific basis. Because syphilis has occurred in a case of paretic dementia, it does not indicate to me that syphilis is the etiological factor. We should try to ascertain if the syphilis is responsible for the lesions. As the essayist has pointed out, the lesions found in paretic dementia are not those of syphilis. The time that has elapsed between the syphilitic infection and the onset of the paretic dementia should also be borne in mind. We should not at once jump to the conclusion that syphilis is the cause of the paretic dementia. That syphilitic toxins—whatever they are—may evoke nutritional disease of the brain-cells can not be doubted, sufficient, indeed, to produce pronounced disease, but we must satisfy ourselves as to what conditions are produced by it, how it impairs nutrition and what action its toxins have. There may be other factors—the various toxemias, or exhaustion, or even traumatism may be the factor in the disease. I am willing to admit that syphilis is a most important factor in the causation of paretic dementia, but it should not be necessarily regarded as the only cause.

Dr. H. A. Tomlinson (chairman)—In considering the possible etiological relationship between syphilis and paretic dementia we should not lose sight of the fact that syphilis is a widely prevalent disease and almost as old as history, while general paresis, or paretic dementia, as the writer calls it, is comparatively infrequent, and, so far as we know, limited to the centers of modern civilization. Furthermore, when paretic dementia occurs in a syphilitic, the manifestations of the latter disease are not conspicuous and do not resemble other syphilitic affections of the nervous system, either in symptoms of somatic involvement or in its histology. Besides, syphilis frequently attacks the brain and produces degenerative disease, accompanied by dementia; that is not general paresis. It may also be claimed that the victims of syphilis and general paresis come from the same general class, and would therefore be equally liable to other possible causes of general paresis.

Dr. Frank P. Norbury, in reply—I do not know that I can add anything further to the discussion. The fact is the Chairman covered the points that I had in mind. One of the speakers referring to stress as a factor in the production of paretic dementia, said that it was a prominent cause. In my experience this is not such a factor as is supposed, for comparatively few of my cases have come from the large cities—the busy centers of civilization—most of them come from the rural districts, and I am quite sure that they were not subjected to any special stress, either in connection with their occupation or social conditions. I believe the neurasthenic class alone succumb to stress. I have never seen a neurasthenic develop paretic dementia. In most of my cases the paretic dementia developed from fourteen to eighteen years after syphilitic infection, while several of them gave no history of infection at all. Yet from my knowledge of them as individuals I knew that they had often been exposed to such infection. In conclusion, I wish to emphasize the importance of the early recognition of paretic dementia. At the beginning of this disease there is a functional stage, as pointed out by Folsom some time ago, and if the symptoms are recognized during this stage we may be able to do something to arrest its progress. If allowed to go on, organic changes occur, with resulting dementia and death.

Clinical Report.

CASE OF SIMPLE FRACTURE OF THE VAULT, WITH MENINGITIS ON THE THIRD DAY. AUTOPSY.

EDWARD T. ALFORD, M.D.
INTERNE IN THE CHICAGO BAPTIST HOSPITAL.
CHICAGO.

The patient, Mr. W., while riding on a bicycle, Tuesday morning, June 1, was struck by a street car and severely injured. He was immediately taken to the Baptist Hospital, entering the service of Dr. Bayard Holmes, at 10:15 a. m. At this time he was conscious; there was no deviation of the eyes, no ptosis and the pupils were neither contracted nor dilated, and they both reacted to light. His hearing was apparently normal and there was no hemorrhage from the ears. There was no aphasia, as speech was normal, and no paralysis in any part of the body was evident. There was a good deal of hemorrhage from the nose and mouth, the upper lip being cut from the left nostril through the lower border of the nasal septum and through the lip a little to the left of the median line. This involved all the structures of the lip. A second wound on the inner surface of the mouth was found extending backward from the right angle of the mouth for the distance of an inch or more. Some of the teeth on the right side of the lower jaw were broken off, and the mucous membrane lacerated; the right lower jaw was fractured with over-riding displacement, the posterior fragment over-riding the anterior. This fracture was shown by crepitus and deformity of the lower dental arch. A small contused incised wound was found over the occipital region and another long contusion at the outer right border of the frontal bone.

The patient was then anesthetized, the occiput shaved, and the wounds about the nose and mouth were carefully sutured and dressed. An attempt was made to reduce the fracture of the lower jaw by the use of a four-tailed bandage, but reduction could not be maintained. Patient was then put to bed.

Tuesday afternoon the patient vomited considerable blood, and that night was delirious for a short time. His temperature at this time was 99.5, pulse 88. On Wednesday morning I examined the patient with Drs. Holmes and Teschan. There was at this time no extravasation of blood under the lids or over the mastoid regions. The pupils were equally contracted, which contraction might have been the result of median line and muscular tonus was normal. There was no deviation of the eyes or ptosis. The tongue protruded in the median line and muscular tonus was normal There was no evidence of blood in the ears and hearing was apparently perfect. His temperature was 99.4 and his pulse 76. In his conversation he seemed rational, but he did not realize his serious condition. On Thursday morning, June 13, an examination showed improvement. There were no evidences of fracture of the base of the skull or compression of the brain. His temperature still remained about 99.4 and his pulse 88. The examinations of the urine were negative. The right lower jaw had become very much swollen and infiltrated.

An examination Friday morning, with Drs. Holmes, Teschan and McCaw, showed no paralysis or spasms of the face, arms or legs. There was no aphasia. There was no deviation of the eyes. The pupils were equally dilated and reacted to light. An extravasation of blood was noticed over both mastoid regions. This extravasation was more marked on the right side, and we thought that there was a slight extravasation under the right eye. Hearing was apparently normal. At noon of the same day he complained of a severe headache; his temperature was 98.6, and his pulse 78. At 3 o'clock in the afternoon he became delirious, got out of bed and walked about the halls. He rapidly grew worse, and about 4 o'clock was put in restraint. At 8 o'clock that night I examined the patient with Drs. Holmes, Boice, Teschan, Biggar, and McCaw; during the examination Dr. Sippy came in. At this time the temperature, per rectum, was 104.4, the pulse 78, and the respiration 25. The restraint which had been applied was removed. Some hemorrhage was noticed from the nose. The pupils were equally dilated. There was no ptosis or deviation of the eyes. Sensation on both sides of the face seemed to be normal. He was easily tickled in either nostril, and when struck lightly on either side of the face he seemed to respond. Two or three times a slight spasm was noticed going up the left side of the face and involving the lids. Extravasation of blood was seen under the right eye and over both mastoid regions. This was peculiar in that it extended above and in front of the ear. The right lower jaw and floor of the mouth were infiltrated and swollen. Kernig's sign was not present. The patient was excited, had illusions and was constantly picking and pulling, with a good deal of force, at objects seen about him.

At this time we assumed from the findings: 1, that there was no compression of the brain, either from depressed bone or hemorrhage; 2, that there was a fracture of the base of the skull in spite of the fact that there was no deviation of the eyes, no ptosis, no hemorrhages from the ears, no apparent loss of hearing, or no paralysis, but from the fact that there was hemorrhage from the nose and extravasation of blood over the mastoid regions and under the right eyelid; and, 3, that the patient was suffering from acute general meningitis, the infection having probably occurred through a fracture in the ethmoid or a fracture through the petrosa into an infected antrum.

The prognosis made at this time was that the disease was absolutely fatal, and that no treatment was indicated. The patient was then put in the care of a strong male nurse, without restraint, and directions were given to watch the patient for two hours or more without treatment in order not to obscure the diagnosis of the case, and after two hours a sedative might be given in sufficient quantities to keep the patient quiet. An ice bag was applied to the head, but no medicine was given until 2 o'clock, when 60 grains of sodium bromid was given per mouth. The patient rapidly grew worse during the night, and had involuntary urinations. His temperature at 5:20 a. m. was 107, his pulse 144, and respirations 58. There was a tendency for his tongue to fall back into the throat and to impede his respiration. He died June 15, at 4 o'clock a. m., while in a general convulsion.

POSTMORTEM.

Permission was given to enter the cranium by the coroner. It was held in the presence of Drs. Holmes and Boice.

The contused wound over the occiput and over the right border of the frontal bone were healthy and showed no redness, swelling or edema. The lower jaw on the right side corresponding to the fracture was very much swollen and densely infiltrated, the base of the tongue was also infiltrated and swollen. Extravasation of blood was seen over both mastoid regions, this extended above and in front of the ears. After dissecting the scalp forward an extravasation of blood was found starting from a crucial fracture of the vertex and extending downwards on both sides of the head in front and back of the ears, thus accounting for the extravasation seen in previous examinations.

The fracture followed the sutures, commencing about the posterior third of the interparietal suture, running forward and extending into the frontal bone for about an inch, turning a little to the right as it entered the frontal bone. It also extended from the interparietal suture along the frontoparietal sutures on either side for the distance of an inch and a half. The fracture opened into the superior longitudinal sinus, and a small thrombus was found along its course extensive enough to cause obliteration of the sinus.

The meninges were injected and somewhat edematous. The ventricles were distended and the cerebrospinal fluid increased in quantity. The brain tissue seemed somewhat softer than normal. The dura mater about the base of the skull was carefully and thoroughly removed and a careful search made for the fracture of the base of the skull, but none could be discovered.

The middle ears were opened and inspected. The drum and ossicles on both sides were normal and there was no evidence of any present or previous inflammation. There was peculiar circular depression about one-half inch in diameter in the middle fossa of the skull on the right side just at the base of the petrous portion of the temporal, looking as though it might have been the result of a previous ulcerative process, but no present pathologic significance was attached to this. Cultures were taken from the spinal cord by subarachnoid puncture and from the ventricles, but showed no growth.

This case is of peculiar interest in three respects: 1. The scalp was apparently uninjured over the seat of the fracture of the vault. 2. The extravasation of blood behind the ears, so common and almost pathognomonic in fractures of the base, came from an unrecognized fracture of the vault. 3. The infection of the meninges must have come through some small and undiscovered fracture into the ethmoid cells, or the offending microbes gained access into the blood from the focus afforded by the swollen and infiltrated jaw and localized in the meninges, causing an acute serious leptomeningitis; or the meningitis may have occurred as a part of a progressive sepsis.

Petrifaction of Kidneys.—More than 400 calculi were found in the left kidney and 60 larger ones in the right, at the autopsy of a young soldier who had died suddenly with heart symptoms. Death was due to enormous dilatation of the heart, as there had been no retention of urine. It is described in *Méd. Moderne*, 1901, 29, as actual petrifaction with consecutive interstitial nephritis and fibrous degeneration.

SATURDAY, SEPTEMBER 28, 1901.

A PREMATURE CRITICISM.

An editorial on the surgical aspect of President McKinley's case in a leading medical weekly calls for some comment. The preceding issue was generally optimistic, as were all at the time from the apparently favorable aspect of the case during the first few days. The editorial under consideration is distinctly critical, and indeed decidedly unfriendly, in its comments on the conduct of the case and the shortcomings of the autopsy. The medical profession as yet has had no full report of the findings, none that in our opinion authorizes us in indulging in unfriendly criticism or in extensive premature generalizations, but this is evidently not the view held in the editorial in question. It admits that while the operation on the President was faultless in its technique and brilliant as far as it went, it was necessarily an incomplete one, but it goes on to say that the surgical judgment of the surgeons was in error, implying that they should have disregarded the necessary limitations of the operation, the patient's condition and the value of the precious time. Attention is given to the autopsy, and while admitting that not one of the principal lesions gave any evidence of its existence during life, the writer talks about "a most startling error in diagnosis," and wants to know why, if it was impossible to follow the course of the ball at the time of the operation, the gentlemen in the case were so satisfied with the "real nature of a wound that they obviously knew nothing about?" The absence of an x-ray examination during life is harshly commented on as if there could be no possible reasons against it, and the insinuation—certainly not a justifiable one as is proven by the evidence submitted at the trial just closed—is made that it was not thought worth while at the autopsy to thoroughly search for and find the bullet. It even goes further than this and speaks of a condition of which we have no evidence whatever, such as a leaking kidney. There is, it seems to us, an evident "I told you so" spirit in the editorial that is unfortunate, to say the least.

We see no reason to change the opinion we have already expressed, namely, that all that medical science and conscientious care could do for the President was done. Whether "under like circumstances in future the gentlemen concerned would act somewhat differently" may be a question, even with the knowledge gained by this experience; the conditions might make it impossible to do more. We do not know that such conditions did not exist in the case of the President, and lacking that assurance we believe such a comment unnecessary and unbecoming. The operation was one to try to the utmost the courage and judgment of those in charge, and we do not feel assured that any others in their place could have done better. To err is human, as our contemporary judiciously quotes, but we do not think it has been clearly demonstrated beyond question that there were any avoidable errors in the management of this historic case.

While we believe that honest criticism is always to be encouraged, on such an occasion as this it would be well to be sure of the absolute truth of the statements on which criticism is based before it is made. A journal claiming to represent the medical profession ought certainly to guard the rights of those it claims to represent so long as truth and facts allow it to do so. There will be time to criticise the management of the case of President McKinley when all the facts shall be revealed in the full report of the case and in the official report of the autopsy. It is well in all cases where there are not the strongest reasons to the contrary that, as a lay journal says, "we should give good men credit for good motives, good judgment and good actions. . . . Some time a valuable life may be lost because the would-be life saver is not at his best and bravest through fear of hostile criticism or carping misapprehension."

RELATIONAL ANATOMY.

Professor Jackson has done a real service in introducing what must be regarded as a new and important *method for preparing and studying gross sections* of the human body, which he described in his paper printed in these columns last week.[1] The great value of the frozen sections made by Braune and others has been generally recognized, but the difficulty of making these sections has hindered many anatomists from using them to the extent which the importance of the study for the acquisition of a knowledge of topography renders desirable.

The formalin injection used by Dr. Jackson fixes each organ perfectly in its natural position. Freezing is entirely unnecessary for the making of sections; they can be satisfactorily prepared with the aid of only a butcher's knife and saw. The principal advantage of the method, aside from its simplicity, lies in the ease with which the preparations may be preserved, handled and studied without danger of injury.

The procedure promises to be of value not only for surgical anatomy but also for the study of human anatomy as a pure science. The student who learns his gross anatomy by dissection alone can not possibly gain a normal conception of the natural relations of the various parts to one another. Dissection consists essentially of the removal of the coarser connective tissues and fat from the body. This has to be done gradually, and while the method permits of the gaining of knowledge concerning the form of the individual gross structures, the student unavoidably loses sight of the real relations of structure to structure as they exist before the tissue has undergone that mechanical analysis which dissection necessitates. If three series of sections—corresponding to the three dimensions of space—through the whole body made by Dr. Jackson's method be carefully studied and drawn the student should be able to make a mental reconstruction of the entire organism of greater practical value to him than that obtainable by any other method. We do not mean by this that dissection is likely to be superseded by a study of such series of sections; on the contrary, thorough and clean dissections are now more important than ever; but it may fairly be prophesied that dissecting-room anatomy will from now on be supplemented in much greater degree than heretofore by some such topographical method as Dr. Jackson suggests. The two methods, that of a study of serial sections and that of dissection, will be reciprocally beneficial to one another.

---

[1] See The Journal of September 21, p. 731.

It is gratifying to note that the topographical method employed has been introduced by a professor of anatomy in a medical college of the Middle West. Now, that medical schools of the better sort in this part of the country have come to recognize the necessity of having the chairs in the scientific branches of medicine filled by men who give their whole time to teaching and investigation, we may hope not only that anatomy, physiology and pathology will be better taught to medical students than they have been in the past, but also that these sciences will from time to time be enriched through the activities of their representatives in the fields of original research.

THE RESORPTIVE POWERS OF THE PLEURA.

This important question has been investigated experimentally by Grober[1] in Stintzing's clinic in Jena. Of the various factors that have been emphasized as promoting absorption from the pleural cavities, Grober does not attach any importance to the aspiration on part of the thoracic duct nor to the *vis a tergo* of the blood pressure and of the tissue fluids. The purely physical forces of osmosis and capillary attraction are of some importance undoubtedly. Whenever accumulations of fluid in the pleural cavities are of less concentration than the blood serum and the lymph, the walls of the vessels in the pleuræ will act as semipermeable membranes and permit currents of fluid to pass into their contents, according to the general laws of osmotic pressure.

Thus Castaigne[2] finds that during the first week of exudative pleuritis the pleural fluid is more concentrated than the serum of the blood. Aspiration would be useless at this time because fluid would rapidly accumulate in the pleural cavities.

But the most important factors are found in the movements of the respiratory organs. During respiration the intrapleural pressure varies as the lungs are pressed more or less firmly towards and against the chest walls; in case the pleural layers come in contact at certain points the fluids in the cavity are pressed into the openings in the wall; and finally as the ribs are separated and approximated the lymph vessels in the costal wall which communicate by openings with the pleural cavity are alternately compressed at some points and extended at others, thus constituting a suction pump. When respiration is shallow and superficial, absorption from the pleura is less marked than when the respiration is normal. And naturally absorption is also dependent largely upon the actual conditions of the tissue in the pleural membranes, whether normal or pathological. It is not at all surprising that absorption is greatly delayed when the pleuræ are the seat of various forms of inflammation. Grober also adduces a certain amount of evidence that the healthy pleura absorbs living micro-organisms and toxins which are thereby rendered harmless. In the inflamed pleura this power is also diminished. To the surgeon and the physician who alike are interested in the removal of pleural exudates Grober's experiments present much of value and interest.

COMPLEXION AND ABILITY.

Mr. Havelock Ellis' recent papers on certain questions of British ability have developed some interesting statistics. He finds from an analysis as regards complexion, of the portraits in the National Gallery, that fair complexion is more frequent among political agitators, soldiers, sailors, scientific men, poets, etc., while statesmen, clergymen, literary men, etc., are predominantly dark. Political agitators and reformers are at the one end of the list, being very largely blonds; the opposite extreme is occupied by actors and actresses, who are almost always dark. So far as Ellis can learn, "no really fair person has ever risen to the highest dramatic eminence in England," and, so far as he has been able to observe, the case is the same throughout Europe. He concludes that excess of fairness prevails among those of restless enterprising spirit, and the reverse is true in the aggregate of dark people, which includes the men of thought rather than of action, the teachers of religion, the humble classes, in short those whose tendency is to practice and preach resignation.

The explanation he gives is that the relation between pigmentation and mental aptitude is chiefly indirect and due to race. The fair man is energetic and restless, it is suggested, because he belongs to an original fair stock of people that possessed these qualities, while the dark man tends to be resigned, religious and imitative, yet highly intelligent, because he belongs to a stock with those characteristics. There are some criticisms that are naturally suggested by these conclusions. In the first place, the figures are too small; the writer generalizes in regard to people of low birth, who are probably not very fully represented in the British National Gallery of portraits, from a dozen individuals. Considering the composite origin of the British race and the frequency of ultra family variations it appears incorrect to speak of anyone belonging to any particular stock, whether fair or brunette. It might be a little better to say, "throws back" to such a stock; but this also is a conjecture. There is no one of the average Britons who has not had a very mixed ancestry in this particular respect; the one pure race, one of the most enterprising and active ones, at least in a business way, is very generally brunette in Great Britain—the Jews. On the whole it would seem better to explain the facts, so far as they exist, by the old temperament doctrine, which has at least a little basis of truth, at the same time recognizing the imperfection of the data and the weakness of any extensive generalization upon them.

MEDICAL EDUCATIONAL STATISTICS.

The task of working up the data and tables which appeared in the educational number of The Journal was one of great magnitude and was rendered all the more difficult by some of the minor schools neglecting requests for information. It is possible that there may have been an error in the matter of some of the figures, but we believe that those given are *practically correct* and that we have presented statistics that have never before been attempted in this country. It will be appreciated if the authorities of the different colleges will verify our work, or notify us in the event of any misstatement that it may be corrected. It is intended that the work shall be carried on in an educational number each year, thus giving reliable information and figures in the matter of medical education. One mistake was made in a note crediting the figures of the population to the United States census of 1890; they were taken from that of 1900.

The table which gave the number of students from the different states in the several colleges was necessarily incomplete owing to the fact that the catalogues of some of the schools do not indicate the state from which the student comes. However, many lessons may be learned from it. It is, for instance, interesting to note especially in regard to the small schools, how the patronage is entirely local.

Considering all physicians in this country, as given by Polk's *Medical Register*, 1900, except army and navy surgeons, we find that there is one physician to each 637 inhabitants. Of the total number, there are about 104,094 belonging to the regular school, 10,944 to the homeopathic, and 4,752 to the eclectic and nondescript schools—in all 119,788. To this number must be added those receiving degrees the past two years, and of course death subtracted. The probability is that in round numbers there are 125,000 licensed physicians in the United States.

After much correspondence the Pacific Coast Regular College of Medicine has been reported as having had 14 matriculants and 7 graduates the past year. This gives a total of 5,451 graduates and 26,431 students registered for the school year 1900-1, and it is thus shown that one of every 2,888 inhabitants was a medical student.

There are in the United States 155 colleges that confer the degree of M.D.—122 of the regular school, 20 homeopathic, and 13 eclectic and nondescript. In our table of medical colleges 159 were shown, but two of these, the School of Medicine of the University of Kansas and the Medical Department of the University of North Carolina, do not grant degrees, the two homeopathic colleges in Kansas City, Mo., consolidated, and the Curtis Physio-Medical Institute, Indianapolis, was believed to be in existence, but nothing authentic has been learned. This gives the almost startling ratio of one medical school to approximately every 500,000 population in this country. Comparing this to the figures shown in some of the other countries: Great Britain has one to every 2,350,000; Germany, one to 2,500,000, and Austria, one to 5,000,000.

TESTIMONIAL BANQUET TO DR. N. S. DAVIS.

The banquet to be given in honor of Dr. N. S. Davis, at Chicago, on October 5, ought to be a notable event. We, in this country, are beginning to adopt the praiseworthy custom of showing our great men that we appreciate them while they are yet with us, and there has been no better opportunity afforded to give honor where it is due than this one. It is sixty-five years since Dr. Davis entered on the practice of medicine and these have all been years of active usefulness and prominence in the profession. His connection with the founding of the American Medical Association would of itself insure him an immortality in our records and memories, but it is only one incident of his leadership in all good works and causes. His active advocacy of higher medical education, which he was one of the first to promote, of higher ethical standards, of temperance, etc., can never be forgotten so long as there is a history of American medicine, and while in his long life of usefulness there may have been many who have differed with him on some details, no one has ever questioned the sincerity and honesty of his opinions or his honorable methods. There is no one living at the present time that the American medical profession ought more to delight to honor, and we are sure that its members will not allow the occasion to pass without showing their appreciation of the opportunity.

LOW BIRTH-RATE NO CAUSE FOR ALARM.

An English clergyman, the Dean of Ripon—in that usual outlet of British feeling, a letter to the *Times*—laments the decrease of the birth-rate in England, which has fallen from 34 per 1000 of the population in 1875 to 29 per 1000 in 1900. At this rate he concludes the birth-rate will in time be entirely suppressed and the climax of England's decadence be complete—*with its final baby*. Such forebodings remind one of Mark Twain's calculations on the length of the Mississippi.

which was continually being shortened by cutting off bends. He calculated the time when Cairo would be a suburb of New Orleans and offered the result as an example of the beauties of statistics which give the largest results of theory for the smallest investment of facts. The birth-rate of England, like that of every modern civilized country with a higher standard of living and diminishing proletariat, tends to decrease, and if this decrease does not progress too far it is a sign of prosperity and well-being of the population. An excessive birth-rate, like that of parts of Russia, means usually an excessive infantile death-rate; children come too often to be properly cared for, and are too common to be duly valued. If the birth-rate falls below the death-rate, of course the result is national extinction; but this has not happened anywhere lately, to our knowledge, except among a few degenerate Indian tribes, etc. Even a low enough ratio to indicate immediately threatening decadence is rare where vital statistics are reliably collected. Those of Great Britain must be beyond any question, but the fall of 5 per 1000 in twenty-five years need not as yet be very alarming.

"SHADOWING."

The Sacramento *Bee,* the paper which was so indefatigable in its opposition to the ostrich policy of the California authorities as regards the plague last spring, publishes a curious detective's bill recently paid by the California State Board of Health. The bill is for "shadowing" Drs. R., F., and W., which the *Bee* interprets to mean Dr Ryfkogel, the ex-bacteriologist of the State Board of Health, who left the board apparently on account of his diagnosis of the plague in the earlier San Francisco cases; Dr. J. M. Flint, bacteriologist of the Marine-Hospital Service, and Dr. J. H. White, United States quarantine officer and successor of Dr. Kinyoun at San Francisco. If these identifications are correct and the paper furnish some evidences supporting them, at least in part, besides its positive editorial affirmation, the question naturally arises why was this bill incurred, and what good has come of such expenditure. "Shadowing" is practiced for two purposes: legitimately to obtain evidence of crime, illegitimately to manufacture evidence of crime. Of what crime have Dr. Ryfkogel and these United States officials been guilty, or what good reason was there of suspecting them of contemplating one? If these questions can not be satisfactorily answered there was no ground for the legitimate use of spies upon their movements. We do not say that the California authorities can not give a good reason, but what it is, is beyond the scope of our imagination. If they have none, the performance is a disgrace to them and an insult to respectable physicians as well as to a department of the public service of the United States.

UMBILICAL INFECTION WITH BACILLUS PYOCYANEUS IN THE NEWBORN.

In an epidemic of so-called umbilical sepsis in Berlin, involving eleven fatal cases, Wassermann[1] found in all umbilical arteritis, one or both arteries being filled with softened thrombi and pus up to their union with the hypogastric artery. In seven cases there was a metastatic focal pneumonia with hemorrhagic and cellular as well as fibrinous exudation, necrosis and abscess formation. In two cases there was an acute fibrinous pericarditis. In the last four cases the bacillus pyocyaneus was obtained in pure culture from the umbilical thrombo-arteritis and the pulmonary foci. This bacillus produced an inflammation around the umbilical arteries and a general infection after application in pure culture to the umbilicus of newly born guinea-pigs. It seems that a continuous grouping of umbilical sepsis like this described by Wassermann is practically a new observation. The constant involvement of the umbilical arteries, while the vein remained free, illustrates the previously noted predilection for infection of the arteries. Runge found the arteries involved 54 times in 55 cases of umbilical sepsis. The explanation given of this marked predominance of arterial infection is as follows: The infection begins in the perivascular tissue, whence it extends to the vascular wall; the connective tissue around the arteries at the umbilicus is double as thick as that around the veins, hence the much greater chance for infection of the arteries. Wassermann reviews the literature of pyocyaneus infections in man and shows that it is especially in infancy that the bacillus of green pus acquires special importance. The occurrence of eleven cases of umbilical sepsis within a period of about six weeks in one obstetrical clinic is in itself somewhat remarkable, and the more so as the cause seems to have been bacillus pyocyaneus. But Wassermann offers no explanation as to the probable mode of infection nor as to the source of the infectious agent.

THE YELLOW FEVER EXPERIMENTS IN CUBA.

The Caldas serum experiments in Havana appear to have come to an end in a way that is decidedly unsatisfactory to the discoverer of this alleged cure. According to the telegrams from Cuba the commission appointed to examine its merits has recommended a discontinuance of all experiments on the ground that Dr. Caldas keeps his discovery a secret, it is said, to favor a company which has been organized for its exploitation, that his claims that, the yellow fever agent is found only in the intestinal tract is not supported by other evidence of mosquito inoculation and direct blood inoculations, and lastly, that his attempt to immunize individuals against yellow fever by his serum has failed. As regards this point there is a question raised by Dr. Caldas; he denies the correctness of the diagnosis of yellow fever in the serum-treated patient by the American physicians. Against this alleged failure he claims a long record of successful experiments by himself and Dr. Bellingzaghi in Brazil and Mexico; hence, he considers the Cuban test inconclusive as regards the merits of the cure. It is hardly possible that there are any material differences between yellow fever in Brazil and Cuba, and that the experts in the latter country are less skilful diagnosticians than Dr. Caldas. His assertion also that the cases in Havana were all instances of blood poisoning from mosquito bites does not carry with it any inherent evidence of probability—accidents of that character do not happen so frequently. It does not appear that any prejudices on the part of the commission on account of his unethical secretiveness to the nature of his remedy stood in the way of their giving it the trial in which it has failed, and any complaint by him on that account is scarcely justified except indeed that he may claim that it was not complete enough. From the telegraphic dispatches it would appear that his methods were not such as to convince the commission of his genuine scientific spirit as an investigator, and the medical profession generally will pardon the members for not desiring to be utilized in furthering any commercial exploitation of a secret formula. If Dr. Caldas goes back discredited he will apparently have himself to thank for his ill fortune.

---

[1] Virchow's Archiv, 1901, clxv, 342-364.

Medical News.

CALIFORNIA.

Santa Fe Hospital.—The Santa Fe system has decided to erect a hospital building in Los Angeles for the use of its employees.

Dr. Harkness' Estate.—The appraisement of the estate of the late Dr. Harvey Wilson Harkness, San Francisco, places its value at $29,343.

Tuberculosis Reports.—The Oakland Board of Health has adopted a resolution recommending an ordinance which will compel all physicians promptly to report cases of tuberculosis to the board.

Dr. Thomas W. Huntington, San Francisco, associate professor of clinical surgery in the Medical Department of the University of California, has been recently appointed professor of clinical and operative surgery.

To Isolate Consumptives.—Dr. John M. Williamson, president of the San Francisco Board of Health, in his annual report, recommends that a separate ward be constructed at the City and County Hospital especially for consumptives.

The new Emergency Hospital, Golden Gate Park, San Francisco, the foundation for which has just been laid, will be ready to receive patients, January 1, 1902. It will have a capacity of 60 patients and is expected to cost more than $8000.

San Francisco Deaths.—The report of the vital statistics for the year ended June 30, 1901, shows that 7008 deaths were registered. Of these 1107, or 15.8 per cent., were from tuberculosis; 713 from heart disease; 691 from pneumonia; and 573 from violence. Only 4877 births were registered during the year.

Personal.—Dr. Theodore F. Johnson, National City, has gone to San Francisco for two months of post-graduate work. ——Dr. Walter M. Boyd, Los Angeles, is dangerously ill with blood poisoning.——Dr. Harry Wilson, who served in Cuba and the Philippine Islands, has left the army and settled at Fresno for practice.——Dr. Herbert A. Johnston, Anaheim, has purchased a residence which he will maintain as a sanatorium. ——Dr. L. Franklin Dozier has been appointed resident physician at the State Hospital for the Insane, Napa, to succeed Dr. Alden M. Gardner.

COLORADO.

Typhoid at Denver.—The Arapahoe County Hospital is now full of typhoid fever patients. They are mostly from ranches or the mountains and not from Denver itself.

New Medical Licensees.—The Colorado State Board of Examiners passed upon and granted licenses to 268 applicants during the year ending June 30, 1901. Of these 232 were regulars, 28 homeopaths and 8 eclectics.

The Sanitary Bulletin of August 31 states that during the month of August, 71 cases of diphtheria, 104 of scarlet fever and 52 of smallpox were reported to the State Board of Health. This shows an increase over July of 5 cases of diphtheria and a decrease in scarlet fever of 142 cases and in smallpox of 11 cases.

CONNECTICUT.

Dr. William H. Barton, New Britain, has been elected pathologist and bacteriologist at the New Jersey State Hospital, Morristown. He will assume the duties of his new position, October 1.

Personal.—Dr. Myron P. Robinson, Terryville, has moved to Windsor Locks.——Dr. James Stretch, Meriden, has located in New Haven.——Dr. Louis E. Cooper, has been appointed medical examiner of Ansonia, vice Dr. William H. Cooper.

Mortality of Connecticut.—The Bulletin of the State Board of Health shows that by mortality reports received there were 1310 deaths during the month of August. This was 13 more than in July, and 332 less than in August of last year, and 151 less than the average number of deaths in August for the five years preceding. The annual death rate was 18.5 per 1000 for the large towns, for the small towns 13.8, and for the whole state 17.3. The deaths reported from infectious diseases were 423, being 32.2 per cent. of the total mortality.

ILLINOIS.

Diphtheria at Maroa has caused the closing of the public schools and churches.

Smallpox has been reported at Jimtown, near Berlin, Sangamon County; Delavan and Springfield.

Dr. Amos F. Moore, Dixon, has been commissioned assistant surgeon, with the rank of captain, and assigned to the Sixth Infantry, I. N. G.

Personal.—Dr. William T. Sloan, health officer of Peoria, has resigned, and Dr. William R. Allison has been appointed temporarily to the position.——Dr. Charles G. Rayburn, Roseville, has located in Kewanee.

Psychurgery.—The Elgin College of Psychurgery has been incorporated by three individuals said to be "doctors," but whose names have for some unexplained reason been omitted from the list of registered physicians of the state. The object of this "college" is to teach drugless healing.

Chicago.

Dr. P. J. H. Farrell has been commissioned major and surgeon and assigned to the Sixth Infantry, I. N. G.

Hold-Ups and Burglary.—Two physicians have been held up and robbed within the last week, and Dr. D. Lee Shaw lost property valued at $500 by a burglary, September 16.

Seven women physicians have been arraigned by the State Board of Health for practicing medicine without licenses and for advertising as physicians. Of these only one name appears on the physicians' register.

Banquet to Dr. N. S. Davis.—The following invitation has been sent out: "You are cordially invited to a banquet and memorial presentation in honor of Nathan Smith Davis, M.D., LL.D., in honor of his long and distinguished services in medicine in its every form of usefulness, to be given by the medical profession of America, in the banquet hall of the Auditorium Hotel, Chicago, Saturday, October 5, 1901, six o'clock p. m. The committee consists of Drs. Christian Fenger, J. H. Stowell, F. X. Walls, W. S. Haines, Edward F. Wells, and Arthur R. Edwards.

Personal.—Dr. Henry S. Zimmerman has bought the property of Dr. John A. Schreck, Cameron, and will locate there. ——Dr. Elmore S. Pettyjohn has returned from Europe and opened an office in suite 902, Stewart Building.——Dr. F. Gregory Connell is taking a month's trip to the Pacific Coast. ——Dr. Joseph M. Patton and family have returned from a two months' vacation in the Alleghenies.——Dr. and Mrs. Lewis L. McArthur have returned from their summer home at Mackinac Island.——Dr. and Mrs. Ralph E. Starkweather and Dr. John R. Neely registered recently at Buffalo.——Dr. and Mrs. Frank Allport have returned from a European tour of six weeks.——Dr. Frank Billings has returned from Mackinac.

IOWA.

The new Mercy Hospital, Fort Madison, was opened this week.

Dr. J. B. Wilson, Ottumwa, is suffering from a severe attack of appendicitis and is at the Ottumwa Hospital.

An emergency hospital is to be provided for Marshall County in Marshalltown. The supervisors have agreed to fit up and equip rooms and an operating room, and the city council of Marshalltown will co-operate.

Personal.—Dr. R. H. Graham has located in Davenport.—— Dr. R. V. Henry, Hedrick, expects to engage in practice in Kellogg.——Dr. N. A. Sloan has opened an office in Pella.—Dr. Francis A. Ely, Clarinda, has moved to Des Moines.——Dr. Joel E. Morrill, Hamburg, has located in Chapman, Neb.—— Dr. Fred J. Graber, Stockport, has moved to Fairfield.

KENTUCKY.

Dr. William Kenney, Paris, is suffering from appendicitis and has been taken to St. Joseph's Hospital, Lexington.

The Louisville Pathological Society resumed its monthly meetings on September 16, after a recess during the summer months.

Communicable Disease.—Smallpox has appeared at Oakdale, and typhoid fever is said to be epidemic near Pellytown, Adair County.

Dr. Matthew K. Gwyn, U. S. M.-H. Service, stationed at Louisville, has been ordered to Manila, where he will be placed in charge of one of the new quarantine stations.

The Conclave Emergency Hospital.—The field hospital at the Triennial Conclave of Knights Templar at Louisville, received and cared for about 40 cases on the day of the procession.

Dr. Ewing Marshall, Louisville, has been selected as medical director of the Interstate Fair. He will organize a medical corps which will attend to all emergency cases during the fair.

Sale of Cocain Prohibited.—The use of cocain and similar drugs has grown to such an extent as to render some action absolutely necessary, and the city council has passed an ordinance prohibiting the sale of such drugs, except on a physician's prescription.

Unlicensed Practitioner.—An individual who has been practicing medicine for two years at Holbrook, Grant County, and who is said to be a member of the North Kentucky Medical Society, has been found to possess neither a license to practice nor a diploma, and has been fined $50 and costs.

Organizing County Health Boards.—Dr. J. N. McCormack, Bowling Green, president of the State Board of Health, and Dr. William Bailey, Louisville, have made a tour of the state organizing county health boards. They visited forty counties and intend to organize a health board in every county in the state.

Personal.—Dr. J. Crittenden Jordan, Rocky Hill, has moved to Coral Hill.——Dr. W. V. Tucker is about to move from Greensburg to Huntsville, Kas.——Dr. Harry B. Kurtz has located in Garfield.——Dr. George B. Young, surgeon in charge of the U. S. Marine-Hospital, Louisville, has returned from his vacation in the East.——Drs. H. Horace Grant, P. R. Taylor and James Vance have just returned from a hunting trip in the wilds of Wyoming.——Dr. Thomas Hunt Stucky, the newly elected treasurer of the Mississippi Valley Medical Association, and Dr. Henry Enos Tuley, the re-elected secretary, have returned to the city from Put-in-Bay.

MARYLAND.

Mortality of Baltimore.—For the week ended September 21 there were 181 deaths, being an annual rate of 18.17 per 1000. The rate for whites was 15.16 and for the colored, 34.88. Births reported, 170.

Vaccination.—The Health Commissioner of Baltimore reports a perfect rush to be vaccinated and that the health wardens are overwhelmed with work. Over 1000 vaccine points were issued in one day last week.

A severe storm on September 15 did great damage to Monteone Hospital for the Insane at Frederick. A portion of the roof was carried away and 1500 window lights were broken. Some of the hailstones drove into the buildings, breaking mirrors and glassware. The stable was wrenched from its foundation, and the corn crop was ruined.

Personal.—Dr. R. Percy Smith, of Baltimore County, has accepted a position in Baltimore Medical College, and will hereafter make Baltimore his home.——Drs. Wm. Osler, Caspar T. Gilchrist and A. Aronsohn, Baltimore, have returned from Europe.——Dr. Louis Stick, resident, and Drs. Louis Rosenthal and Albert Conroy, assistant resident physicians at the City Hospital, have resigned.

Sewer System for Baltimore.—The mayor, in a message last week to the new city council, calls its attention to the act of the Legislature of 1901 empowering the mayor and city council to provide a general sewer system for Baltimore. In the interest of the health of the community he urges that the power thus conferred be at once exercised. The act requires that the question be submitted to the people of Baltimore by a city ordinance.

Appropriations for Charities.—The total amount asked for by the Department of Charities and Corrections, Baltimore, for next year is $340,220. Of this $119,400 is for the care of the insane, $62,000 for city patients in hospitals, $34,770 for destitute and neglected children, and $106,700 for the City Almshouse. At the latter institution there is room for only 360 insane, while 405 are being cared for, including 151 colored. An increase of $15,000 over last year for the insane and of $2500 for the case of the sick is asked for. The hospitals of the city now carry more charity patients at their own expense than ever before. The board proposes to investigate the financial condition of all patients, as many of them should properly be taken care of by their relatives.

MASSACHUSETTS.

Dr. Arthur R. Perry, city physician of Somerville, has resigned.

The City Emergency Hospital, Boston, will be ready to receive patients, October 1. It is a three-story building thoroughly equipped and with a roof garden, which is rather a novelty in a hospital.

Consumptive Hospital.—Boston has now $150,000 available for the erection of a hospital for consumptives. The mayor has sent to the city council a draft of an ordinance creating a new department to deal with chronic diseases, including consumption.

Personal.—Dr. Percy H. Brigham, Dorchester, has opened an office in Brockton.——Dr. Leslie H. Hendee, Palmer, has sold his practice to Dr. J. Homer Miller, Boston.——Dr. Joseph C. Boulay, Three Rivers, has moved to Ware.——Dr. Henry C. B. Snow, Ashland, Buzzard's Bay, has located in West Somerville.

Hospital Bequests.—By the will of the late Charles H. Hayden, Boston, $100,000 is given to the Massachusetts General Hospital and $50,000 each to the Children's Hospital and the Massachusetts Eye and Ear Infirmary. Clinton Hospital receives $2000 by the will of the late John W. McNamara, of Clinton.

MINNESOTA.

Hamline University, Medical Department, Minneapolis, held its opening exercises, September 18. Professor Charles F. Dight delivered the address.

Swedish Hospital.—The contract for the new Swedish hospital, Minneapolis, has been let for $24,000, not including the plumbing or the heating plant.

Dr. Robert I. Hubert, St. Cloud, has been bound over to the grand jury on the charge of having failed to report cases of contagious disease to the local board of health.

Smallpox is under control in the northern part of the state, but in the southern portion the disease is more prevalent. Dexter, in Mower County, and Okaberia, in Jackson County, have been placed under quarantine.

Personal.—Dr. Edmund B. Johnston, Fairmont, intends to locate in Benson.——Dr. Albert W. Shaw, Everleth, has gone to Buhl, where he has been appointed physician of the Drake and Stratton works, and also for several mines in the vicinity.

Seek Sanatorium Site.—Drs. H. Longstreet Taylor, St. Paul, George S. Wattam, Warren, and James L. Camp, Brainerd, the commission appointed by the governor to look for a suitable site for a state sanatorium for consumptives in the northern woods, is visiting Grand Rapids, Cass Lake and Bernidji.

MISSOURI.

Ensworth Medical College, St. Joseph, opened September 16, with an enrolment of 58 students.

Personal.—Dr. Irwin Phillips, Lead Mine, is seriously ill with blood-poisoning contracted during an operation in June last.——Dr. Charles E. Houser has moved from Gentry to Burlington.

Changes at State Asylum.—The board of managers of the State Hospital for the Insane, No. 3, Nevada, met September 3, and elected Dr. James W. Smith, Pleasant Hill, to succeed P. B. Stratton. Drs. L. M. Thompson, Atlanta, and J. M. Angle, Smithton, were elected assistant physicians.

MONTANA.

St. Peter's Hospital, Helena.—The work on the new $60,000 building for the hospital will begin soon.

New County Hospital.—The commissioners of Silver Bow County have decided to erect a new county hospital at Butte, to cost $20,000.

Personal.—Dr. Ellis P. Townsend, Billings, formerly local surgeon of the Burlington railway, has been appointed physician to the Crow Agency.

The Detention Hospital recently erected for Lewis and Clarke County, at Helena, at a cost of $4000, has been accepted by the county commissioners.

Railroad Hospital Enlarged.—The Northern Pacific Railway hospital, Missoula, has had an addition constructed which nearly doubles the capacity of the institution, and which will be ready for occupancy, October 1.

Vaccination Not Compulsory.—The attorney-general of the state has decided that the State Board of Health has no power to enforce vaccination of school children. If any authority exists it is under the general police powers of the state exercised for the purpose of preventing the outbreak of contagious diseases.

NEBRASKA.

Dr. B. B. Hauser, formerly located near Admah, has purchased the office and residence of Dr. William O. Wisner, Hooper, and will locate there.

Fatal Fire at Norfolk Asylum.—Eight of the eleven buildings of the State Insane Asylum were destroyed by fire, September 23. The building contained 300 insane people, seven of them women, who were rescued with the utmost difficulty. Two patients were fatally burned and a third was seriously burned and slightly injured. The fire was discovered about 3 o'clock in the morning in a subcellar, and burned slowly until about 10 o'clock. The entire building is gutted, but the walls are standing and apparently in good condition. The loss to the state is $150,000, with no insurance. The institution is situated two and a half miles from Norfolk and depends for fire protection upon its own water system. The supply of water gave out very soon after the pump was started, and from that time on the hospital force, together with the fire department and hundreds of willing spectators who had responded, were compelled to stand idle. The worthlessness of the fire protection at the institution has been repeatedly made the subject of reports by former superintendents, but legislatures have failed to act.

NEW HAMPSHIRE.

Dr. James T. Greeley, Nashua, secretary of the State Board of Medical Examiners, has sailed for Europe, where he will spend several months in study.

Personal.—Dr. Orlando B. Douglas, New York, who has spent his summers in Suncook for ten years, has opened an office in Concord.——Dr. E. L. Sawyer, Exeter, has sold his residence to Dr. Alice G. Chesley, and will retire from practice.

NEW JERSEY.

Typhoid fever is said to be epidemic in Dunellen.

Isolation Hospital for Newark.—The Common Council has voted $20,000 for the construction of a new isolation hospital for Newark.

Middletown's Pustulous Disease.—A contagious pustular epidemic disease has broken out in Middletown, which is declared not to be chicken-pox or smallpox. The disease is called new and mysterious.

Diploma Vendor Surrenders.—"Dr." J. W. Norton Smith, whose Central University of Medicine and Science in Jersey City, of which he was president, came into disrepute because it granted degrees of various grades at $5 apiece, or two for $7.50, and who has been wanted for almost a month by the police officials, surrendered himself, September 13. He was promptly arraigned in the First Criminal Court and released under $200 bail. It is expected that he will immediately call a meeting of the stockholders of his university and dissolve the institution. By this practical forfeiture of his charter, the university having been legally incorporated, the prospect of further harm in the matters of undeserved degrees will be wiped out and the case will be dropped.

NEW YORK.

French Hospital.—The French Benevolent Society is to build a hospital in New York City to cost $500,000. It will be a stone and brick structure, seven stories in height, absolutely fireproof, and will accommodate 150 patients.

Prof. Simon Harry Gage, Cornell University, gave some demonstrations, with a projecting microscope, before the Pathological Section of the Buffalo Academy of Medicine, of embryological specimens, including some abnormalities.

The Austro-Hungarian Hospital, with thirty beds and a dispensary, was opened for the reception of patients, September 16. The medical staff is composed of Drs. John Guthman, Ignatz M. Rottenberg, Max Landesmann, Bartholomew Lefkowics and others.

Personal.—Dr. Eugene E. Heriman, resident physician at the Albany County Hospital, has resigned.——Dr. Thomas Cunningham, interne at the Albany Hospital, has resigned on account of ill health, and Dr. Clayton K. Haskell, Saratoga, has been appointed his successor.——Dr. David R. Bowen, Wellsburg, will soon locate in Marcellus.

New Medical Directory.—The Medical Directory of New York, New Jersey and Connecticut for 1901, published by the New York State Medical Association, has just been issued. It comprises more than nine hundred pages, containing the names and addresses of physicians legally registered in New York, New Jersey and Connecticut, and much additional information valuable to the profession. The total number of names contained in the lists of physicians is 12,644, of which 10,112 are in New York, 1472 in New Jersey, and 1060 in Connecticut.

NORTH CAROLINA.

Smallpox is said to be raging in Granville County and quarantine has been established.

Transfer of Hospital.—The James Walker Memorial Hospital, Wilmington, has been formally transferred to the city and New Hanover County. Dr. Thomas Meares Green has been elected superintendent and physician in charge.

Personal.—Dr. R. T. S. Steele, Roberdel, has been appointed assistant surgeon of the Atlantic Coast Line with headquarters at Wilmington.——Dr. A. C. Woodruff, Sparta, has located in Independence, Va.

New School of Medicine.—The executive committee of the Wake Forest College board of trustees, which met at Raleigh recently to consider the question of the establishment of a school of medicine in connection with the college, has decided to postpone action in regard to the matter until next June.

NORTH DAKOTA.

Smallpox.—It is reported that eight cases of smallpox have developed among the laborers on the Northern Pacific Railway, west of Bowdon.——Carrington has one case of smallpox securely quarantined.

To Build Isolation Hospital.—Fargo and Cass County will, jointly, build an isolation hospital. It will be modern in every respect, with sewer and water connections.

Vaccination.—The Board of Education of Valley City has decided that pupils of the public schools must be vaccinated before being permitted to enter, unless satisfactory evidence is given that they have been properly inoculated heretofore.

OHIO.

Scarlet fever is reported to be epidemic in La Rue, and the schools of that village have been closed.

Medical Staff for Fall Festival.—The Medical Relief and Emergency Hospital of the Fall Festival, Cincinnati, will be under the charge of Dr. John L. Davis, medical director, assisted by eighteen physicians who have volunteered their services without pay.

More Room Needed.—The Protestant Hospital, Columbus, is so overcrowded that the trustees contemplate enlarging the hospital, and for the time being will obtain a house for the nurses, which will permit the fifteen rooms now used by them to be given to patients.

Personal.—Dr. J. Phil. Schilling has moved from Louisville to Canton, where he will be associated in practice with his son, Dr. Charles E. Schilling.——Dr. S. D. Good, Newton Falls, has sold his practice to Dr. H. McA. Mealy, of Palmyra, and will take six months' post-graduate work in New York.——Dr. Thomas A. Mitchell, Owensville, has moved to Cincinnati.

OKLAHOMA.

Smallpox has again appeared at Guthrie.

Certificates Granted.—As a result of recent examinations, the Superintendent of Health of the territory has granted certificates to practice to 27 practitioners.

Appointments.—Dr. Richard Foster, Hobart, has been appointed superintendent of the Board of Health of Kiowa County.——Dr. Richard W. Brown, Kingfisher, has been appointed superintendent of the Board of Health of Kingfisher County.

County Boards of Health.—The superintendent of the Territorial Board of Health has appointed practically all the members of the various county boards of health, and urges the necessity of a joint session to confer on measures against contagious disease.

SOUTH CAROLINA.

Rhett Memorial.—The friends of the late Dr. R. Barnwell Rhett, Jr., Charleston, propose to endow a room in the St. Francis Xavier Infirmary in memory of him, which shall be known as the Robert Barnwell Rhett room.

Personal.—Dr. James H. Downey has removed from Pacolet to Gainesville, Ga.——Dr. J. Mercier Green, Charleston, has been elected health officer, vice Dr. H. B. Horlbeck, deceased. ——Dr. William Mazyck has been elected dispensary physician of Charleston, vice Dr. Henry Horlbeck, resigned.

Decision on Medical Law.—In reply to a question regarding the eligibility to practice of a three-year graduate, the attorney-general has decided that the amendment to the medical law "does not refer to a graduate who has taken a four years' course, but refers to and is descriptive of a 'college which has a four years' course of instruction.' The limitation applies directly to the institution. When the college conforms to these qualifications and issues a diploma to a graduate, whether he has attended three years or five or six years, the mere granting of the diploma and the evidence of his standing having been made to the State Board of Examiners the graduate is exempt from the provisions of section 970, volume I. of the revised statutes of 1893, and the criminal statutes above cited do not apply to such a graduate."

SOUTH DAKOTA.

St. Luke's Hospital, Aberdeen, is practically completed and will be ready to receive patients in a few days.

Smallpox has broken out afresh on the Sisseton reservation and has been carried from there to Poplar Creek.

Dr. Tillison J. Wood, Huron, has been commissioned assistant surgeon in the South Dakota National Guard with the rank of first lieutenant.

Compulsory Vaccination.—The Board of Health of Mitchell has passed a resolution providing that all persons residing in the city of Mitchell, and all persons attending school in said city who have their homes elsewhere, shall be vaccinated as a preventive of smallpox before Oct. 1, 1901. Provided that all persons who furnish a physician's certificate of having had smallpox, or of successful vaccination, during the three years last past shall not be required to comply with this order.

TENNESSEE.

City Hospital to be Finished.—The Knoxville City Council has passed over the mayor's veto, an appropriation of $2000 to complete the new City Hospital, which will be ready to receive patients about October 15.

Oil vs. Mosquitoes.—The health officer of Knoxville has commenced a crude oil crusade against mosquitoes in and around Knoxville. He proposes to cover all pools with crude oil once a month until cold weather comes.

Gift for Meharry Medical College.—The Meharry heirs have pledged a gift of $10,000 for Meharry Medical College, Nashville, and have also promised to endow a ward in the new hospital to be built in connection with the college.

Communicable Diseases.—Scarlet fever has appeared in several localities in South Weakley County, in Side View, Sumner County and in Charleston. In the latter place the schools have been closed and a rigid quarantine instituted.—— Diphtheria is raging near Indian Mound, Stewart County. ——Whiteville has had three cases of smallpox of mild type.

Personal.—Dr. Frank A. Jones, Memphis, is convalescing at Tate Spring, East Tennessee.——Dr. Gideon H. Morgan, Rogersville, has moved to Fountain City.——Dr. Walter S. Nash has resigned from the chair of bacteriology in Tennessee Medical College, Knoxville, and has been succeeded by Dr. W. R. Lockett.——Dr. Howard Gunn, Gadsden, has located in Guntersville.——Dr. Marshall M. McRee, Trenton, has opened an office in Grapevine, Texas.

UTAH.

Dr. George W. Middleton, Paragoonah, starts for Europe this month to take post-graduate studies in Germany.

Salt Lake City Hospitals.—The St. Mark's and the Hospital of the Holy Cross are recipients of $10,000 each, given without conditions, by General Palmer and George F. Peabody. Four emergency hospitals are to be erected in the mining districts—one each at the Sunnyside, Castlegate, Winter Quarters and Clear Creek mines. For this purpose $20,000 has been donated by the former president and vice-president of the Rio Grande Western Railway, General William J. Palmer and George Foster Peabody.

VIRGINIA.

Smallpox.—Another case of smallpox has developed in Lynchburg, the first in several months.

A Pasteur department has been opened at the University College of Medicine, Richmond. It is in charge of Dr. Adolph G. Hoen, formerly of Johns Hopkins University, Baltimore.

Personal.—Dr. Thomas R. Marshall has returned to Bedford City after two years of service as surgeon of the Forty-first Volunteer Infantry in the Philippine Islands.——Dr. Samuel I. Conduff, Hollins, has moved to Salem.

New Physicians.—At the examination recently held at Staunton by the State Board of Medical Examiners, 102 applicants passed. Of these 28 were graduates of the University College of Medicine, Richmond; 18, of the University of Virginia, Charlottesville, and 22 of the Medical College of Virginia, Richmond.

WASHINGTON.

Unlicensed Practitioners.—Dr. W. H. Fahnestock, Walla Walla, and Dr. Edmund Bunton, Spokane, have been arraigned for practicing medicine without a license.

Personal.—Dr. Charles E. Case, Tacoma, has gone to New York to take a post-graduate course in medicine.——Dr. Ella J. Fifield, district supreme medical examiner of the L. O. T. M., has returned to Tacoma from Port Huron, Mich.

New Hospitals.—A permit has been issued for a three-story addition to Sacred Heart Hospital, Spokane, to cost $9000.——The directors of St. Luke's Hospital, Spokane, expect to begin work on the new $100,000 building this fall.—— Endowment of free beds at the Seattle General Hospital was secured at a mass meeting held recently at the Opera House, at which a handsome sum for this purpose was subscribed.

GENERAL.

Professor Czerny, of Heidelberg, is making a prolonged visit in the United States. He is at present in New York State.

Capt. H. Eugene Stalford, assistant-surgeon U. S. army, Manila, has been appointed attending physician to the civil employes of the Philippine Islands.

Isolation of Leprosy in Hawaii.—A stockade has been built around the buildings containing the lepers at Molokai Island. The Board of Health adopted this method to prevent relatives and friends from coming into personal contact with members of the colony.

Dr. Dedrick Left in the Arctic Regions.—Dr. T. S. Dedrick, of the Peary Arctic expedition, resigned, owing to a dispute with Lieutenant Peary, and went ashore at Etah, the headquarters of the North Greenland tribe of Eskimos and the farthest northern settlement. He refused to return to the arctic steamer *Erik*, and was supplied with arms and ammunition.

Beck's Letters from America.—The *Munich Med. Wochenschrift* is publishing a series of letters from Carl Beck, of New York, describing the St. Paul meeting of the American Medical Association and the medical trip to Yellowstone Park. They are bright and entertaining, and give a very good idea of the proceedings at the meeting and the views presented by men whose names are almost as familiar across the water as at home. He makes merry over the incident of the "Frauenrechtlerinnen and the canteen," which has particular zest for his German readers, as the "woman's rights movement" in any form meets but little sympathy from the profession there.

Dr. Rixey Surgeon-General of the Navy.—It has been reported that Dr. Presley M. Rixey, who during the last few months has become prominent as the physician of President and Mrs. McKinley, will be appointed surgeon-general of the Navy at the expiration of Surgeon-General Van Reypen's term of service. This will not be until Nov. 14, 1902, but his commission as surgeon-general expires December 28 next, and it is possible that Dr. Rixey's appointment may be expected then. Dr. Rixey has been the physician of President and Mrs. McKinley since 1898, succeeding Dr. Leonard Wood when the latter organized the rough riders. He was born at Culpepper, Va., in July, 1852, was graduated from the Medical Department of the University of Virginia in 1873, and entered the Navy as assistant-surgeon in January, 1874. For the first three years he was on various vessels belonging to European, South American and home squadrons, but since 1887 he has been on special duty in Washington nearly all the time.

The President's Case.

Trial of Czolgosz.—The trial of Czolgosz, the assassin of President McKinley, is now ended and the prisoner has been found guilty of murder in the first degree and sentenced to death. At the request of the Erie County Bar Association, Dr. Carlos MacDonald, New York, examined the prisoner and pronounced him sane. His sanity has been also proclaimed by Drs. Joseph Fowler, Floyd S. Creyo, and James W. Putnam, who examined him at the request of the prosecuting attorney. Dr. Harvey R. Gaylord was the first medical witness. He testified that he performed the autopsy and stated that back of the stomach was a track filled with dark fluid matter into which he could insert the tip of his finger. The pancreas was involved; the cause of death was the gunshot wound and the search for the bullet was not continued after the cause of death had been determined. He asserted that the stomach had been affected by the gangrene and that the kidney showed changes which could have been caused only by wounds during life. The wounds in the stomach were not necessarily the cause of death, but the fundamental cause was the absorption of the broken-down matter in the pancreas. Dr. Herman Mynter described the operation, which he, together with Dr. Matthew D. Mann, performed upon the President. After the wound in the stomach had been closed, as the President's temperature was rising, it was agreed by the physicians that the further course of the bullet should not be followed, and on their advice the President was removed to the residence of Mr. Milburn. Dr. Mynter stated the cause of death primarily as gunshot wound, but that it was directly due to blood poisoning from the absorption of poisonous matter caused by gangrene. He stated that the pancreatic fluid escaped, not by reason of direct injury to the pancreas, but by deterioration of the tissues surrounding it. He stated in addition that the physicians who performed the autopsy tried for four hours to locate the bullet and that the President's representative refused to allow the autopsy to proceed further or to permit more mutilation of the body, which would have been required. Dr. Matthew D. Mann, who operated on the President, testified that it would have been necessary to remove the bowels from the abdominal cavity in order to find the track of the bullet back of the stomach, and that this procedure would probably have resulted fatally, as the President had already begun to grow weaker as the result of the operation. He stated as the cause of death, gunshot wound in the stomach resulting from the bullet that passed through both the walls of that organ and lodged in the muscles of the back.

Bullet Not Poisoned.—The theory that the bullet causing the wound which killed President McKinley was poisoned or was steeped in a virulent culture of pyogenic bacteria, is disproven. City Chemist Hill, who holds the professorship of chemistry at the Medical Department of the University of Buffalo, reported to the prosecuting attorney that the bullets examined by him chemically and bacteriologically revealed nothing.

Examination of Cultures in Progress.—The examination by Drs. H. R. Gaylord and Herman G. Matzinger of the cultures taken at the autopsy on the President, as also of sections, is still in progress. As soon as completed the findings will be embodied in the official report of the case.

CANADA.

An examination for barbers is favored by the Trades Congress which has been in session at Brantford, Ontario, during the past week. The Federal Government will be petitioned to enact a law making it necessary for all barbers to procure a certificate of three years' apprenticeship and pass an examination before a board appointed by the government, and that the government establish a proper system of sanitary inspection for barbers' shops.

Prof. Goldwin Smith has donated $10,000 for the library of the University of Toronto. The gift is a timely one in view of the straightened circumstances of the university. The gift will manifest the esteem of Dr. Smith in the university and will also pay tribute to the memory of the restorer of English learning, the present time being the millenary of King Alfred, who is the patron hero and legendary founder of Professor Smith's old college at Oxford.

The Death of the President.—As evidencing the high esteem and affection felt for the sorrowing nation to the south of us, all Canada took on a mournful aspect on the day the body of the late Chief Magistrate of the United States was consigned to its final resting-place. Lord Minto, the Governor-General, by official proclamation, declared that the day should be solemnly observed throughout the Dominion and that His Majesty's subjects should abstain from all forms and sorts of amusement.

"Christian science" Suffers in the Toronto Police Court.—What is described as the hottest attack ever made on "christian science" in the city of Toronto took place on the morning of the 19th inst., during the preliminary investigation in a charge against a father that he had killed his little 6-year-old son by omitting to send for a physician when he was suffering from diphtheria. Police Magistrate Denison did his best to get a description of the "silent" treatment, but was unsuccessful. The crown attorney who was prosecuting the enquiry characterized the fake as follows: "I have no hesitation in saying that this 'christian science,' as set out in Mrs. Eddy's book, is the most damnable blasphemy I ever heard or read." The crown attorney then proceeded to read extracts from the book, when he was interrupted by the magistrate enquiring: "Is that woman still at large?" "Yes, she got this message from God copyrighted." "Oh," said the magistrate, "that shows she's sane enough in one respect." The magistrate and the crown attorney having strongly expressed themselves that this sort of treatment on young children must be stopped, the father was committed for trial at the coming sessions.

Royalty at McGill.—His Royal Highness, the Duke of Cornwall and York, opened the new medical buildings of McGill on the 19th inst. The formal proceedings were opened with an address from the Dean, Dr. Craik, who offered on behalf of the Medical Faculty, teachers, students and workers, a most respectful welcome to their Royal Highnesses. In this address Dr. Craik gave the history of McGill since 1824, when the total number of students was only 25. At the time of its incorporation with the University, the year 1829, the number had only reached 30. Last year the number of students enrolled was 490. In 1824, four professors comprised the teaching staff; now there are 70. The present new buildings are given to the staff by two members of Lord Strathcona's family, Lady Strathcona and the Honorable Mrs. Howard. At the close of the address, a little casket of the labradorite—a native Canadian metal from [illegible] a key of solid gold was presented to His R[illegible] Duke made suitable acknowledgment for the Duchess and himself, after which he declared the buildings opened for the work set apart for them. A visit to the Royal Victoria Hospital followed this function.

FOREIGN.

Contagious Diseases in London.—Smallpox appears to be increasing in London; there are about 200 cases isolated in hospital ships. Typhoid fever is quite prevalent, due, mainly, it is said, to infected suits of khaki brought from South Africa, either for sale or as family heirlooms.

Changes at the University of Leyden.—Professor Korteweg, of Amsterdam, has accepted the chair of surgery, vacant since the death of Van Iterson. Van Walsem, the prosector at the largest insane asylum in Holland, has been appointed successor to the late Siegenbeek van Heukelom, whose works on medical ethics and medical jurisprudence have won him a reputation. The first post-graduate course in Holland has recently been inaugurated at Groningen, and Leyden will soon have one.

Death of Dr. Thudichum.—Dr. J. L. W. Thudichum died in London, September 7, from cerebral hemorrhage. He was born in Germany, near Giessen, in 1829, and studied in that city and Heidelberg, graduating at the former university in 1851. He settled in London in 1853, and devoted his attention thereafter to chemistry. In 1865 he was appointed lecturer on pathological chemistry at St. Thomas's Hospital and director of its chemical and pathological laboratory. His publications are numerous.

Steffan's Title.—Dr. Steffan, by repudiating the title of Sanitätsrath offered him, has conferred a benefit on the entire profession in Germany. He repudiated the title on account of the assessed fee of 300 marks, and the official decree withdrawing the title states that the medical profession is called upon so often in matters of public health and has had such responsibilities and obligations placed upon it in the matter of contagious diseases and the public health in general, that its members are quasi-public officials to a certain extent, and consequently, henceforth, no assessment will be made when a title is conferred upon a physician, as when it is conferred upon a private individual.

Silver Jubilee of Prof. B. S. Schultze.—The pioneer of gynecology in Germany is celebrating this year his silver professional jubilee. The list of his works and articles on subjects connected with obstetrics and gynecology includes 139 titles. His large work on the "Treatment of Alterations in the Position of the Uterus" has been translated into several languages, and investigation by combined bimanual examination which Schultze and Hegar inaugurated, opened a new era in gynecology. He also called attention to the benefits of laminaria, and of exploratory tamponing for the detection of chronic endometritis with slight secretion. His "Manual of Midwifery" is in current use as a text-book in Russia, Spain, Italy and Roumania, as well as in Germany, where the twelfth edition has recently appeared. Schultze's name is best known, however, by his method of resuscitating apparently still-born infants, which is generally recognized as the most effective and most harmless method yet devised, as E. Fraenkel states in a review of his professional career, published in the last *Deutsche Med. Wochenschrift.* His father and older brother were both professors of anatomy.

LONDON LETTER.

Outbreak of Smallpox in London.

After enjoying practical immunity from smallpox for several years a severe outbreak has occurred. A week ago there were 15 cases on the hospital ships; now there are between 60 and 70. The outbreak has practically developed within the last seven days and so far has been confined to the northwestern district. Thirty cases have been notified in three days. The medical officers of health are taking every precaution to hunt up the cases and by careful disinfection to prevent the spread of the disease. In connection with this, as with a previous outbreak, the fact has become apparent that comparatively few medical men are competent to diagnose smallpox in its earliest stage, because the disease has become so rare that most of them have never seen a case. There has been only one death, and the outbreak is judged to be very mild. London is not regarded as a place of origin of smallpox and it is believed that this outbreak will be traced to some external source.

Koch Criticised.

A good deal of adverse criticism has been showered on Professor Koch since the Tubercu' hum. I the bride At the autumn conference of the Sanitary Inspectors' Association, which has just been held, Sir James Crichton Browne read a paper on "Tuberculosis." He said that the sound of Dr. Koch's voice had hardly died away in St. James' Hall when Lord Lister uttered words of protest. Since then there had been a steadily rising tide of opposition and a growing accumulation of evidence against Koch's doctrine. This great Nestor was premature in his announcement and unfortunate in the choice of an opportunity. The question would, he had no doubt, be settled by a government inquiry. Meanwhile, it would be wise for sanitary inspectors to act as if Koch had never spoken.

Prevention of Lead Poisoning in Pottery Glazing.

According to a report made to the government by Professor Thorpe, the use of raw lead compounds in glazing pottery is no longer necessary, and this source of lead poisoning can be eliminated. Fritted lead, which is produced by fusing silica or other material with raw lead so as to form a definite compound—silicate or boro-silicate of lead—answers all purposes. "Fritts" may be soluble or insoluble in acids. The former are little less poisonous or soluble than raw lead itself; the latter are almost innocuous. The proportion of lead in fritts may vary widely—from 15 to 55 per cent.—without any increase in the solubility of the lead. Thus, manufacturers of pottery have a considerable margin of choice in innocuous compounds. In 1899 special rules were proposed by the Home Office: 1, that lead shall be fritted; and 2, that the fritt shall be practically insoluble in acids. A maximum solubility of 2 per cent. was suggested. The manufacturers objected and complained that they were asked to accept conditions "never before employed by any potters in the world." But Professor Thorpe points out that this standard is reached without difficulty in large works abroad. Here as in other matters the unreasonable conservatism of the British manufacturer is the obstacle. But without doubt the result of this report will be that Parliament will compel him to use only fritted lead in glazing.

Paralysis after Dislocation of the Shoulder.

At the polyclinic, Mr. Hutchinson showed the following remarkable case: The patient was a boy, aged 16, who six months previously was caught in machinery and sustained a subcoracoid dislocation of the shoulder, which was reduced about two hours later without difficulty. Loss of power in the arm followed, from which he was slowly recovering. Three months after the accident there were anesthesia of the ulnar side of the hand involving the little and ring fingers, hyperesthesia in the median area, over-extension of the metacarpophalangeal joints and flexion of the phalangeal joints, paralysis of the ulnar interossei, inability to flex the fingers or bring them together, wasting of the thenar and hypothenar eminences, and inability to oppose the thumb to the finger-tips. Passive movement and massage were used. When the patient presented himself at the clinic there were almost complete paralysis and loss of sensibility in all the structure supplied by the ulnar nerve. The fingers were flexed on the palm but could be extended. The wrist was in a condition of partial drop but could be extended at will, though only feebly. Movements of elbow were free but flexion was accomplished almost entirely by the supinator longus, which was large and vigorous, the rest of the forearm being wasted. The triceps was also vigorous, but the biceps and trachialis anticus were very weak and atrophied. Sensibility was present in all parts except in the area of the ulnar nerve, but probably it was below normal everywhere. The muscles of the upper arm were weak, except the triceps and shoulder muscles.

Mr. Hutchinson pointed out that nothing in direct connection with the dislocation would explain the paralysis. Rupture of the circumflex nerve and paralysis of the deltoid sometimes occurred, but so long as the clavicle remained intact it was extremely improbable that the brachial plexus as a whole could be injured. He inquired minutely as to the nature of the injury. The lad said that a revolving wheel seized his coat and dragged on his arm and struck it with considerable force in the upper third on the inner side, where a large bruise followed. Mr. Hutchinson concluded that the nerve trunks in the upper arm were severely bruised, the ulnar nerve being almost disorganized, and the musculo spiral nerve being struck after it gave off its branch to the supinator longus. The incompleteness of the paralysis and the steady progress towards recovery fitted well with this suggestion. He referred to more or less similar cases of paralysis of the nerves of the arm after dislocation of the shoulder which had been recorded by Duchenne. But this writer gave no details of the nature of the injury which caused the dislocation, and though he was aware of the difficulty of explaining the paralysis and quoted Malgaine as to the impossibility of injuring the brachial plexus by a dislocation of the shoulder, he suggested no alternative hypothesis.

Eradication of Rabies from England.

According to the government report recently issued, "During 1900 no case of rabies was confirmed in England or Scotland, and it may be stated with some confidence that the disease which has been present for so many centuries has been eradicated." During the last four years rabies has been confined to the Welsh counties of Brecon, Caermarthen, and Glamorgan, in which six cases in dogs, four in cattle and one in a horse occurred. Credit for this splendid achievement is due to Mr. Walter Long, minister for agriculture, who has enforced an order for muzzling dogs in the face of much opposition. The gratitude due to him and the veterinary department is more apparent when it is remembered that in France 2000 to 3000 cases are annually reported, and that in Italy nearly five times as many cases were declared in 1900 as in 1899; that in Belgium the disease is on the increase; that in India and America it is still present.

Plague.

At the Cape, for the week ending August 17, only 3 fresh cases were recorded, 2 in colored persons and one in a native. The total cases up to August 17 were as follows: Cape Peninsula 357, Port Elizabeth 18, and all other places 2.

Correspondence.

The Septic Tank.

VANCOUVER, B. C., Sept. 14, 1901

To the Editor:—In your issue of August 24, you refer to the sewage disposal at Stratford, Ont., which I understand is by means of the septic-tank system. Your remark that this is the only system of its kind in Ontario, and probably in Canada, is not quite correct, for I am sure that the city of Vancouver, B. C., was the first to introduce it into the Dominion. The septic-tank system has been in operation in Vancouver for six months and is giving the very best satisfaction. The neighboring city of Victoria is also installing it, and Seattle, Wash., is observing its operations closely with the view of adopting it in the near future, if in further time its success is fully demonstrative, which I thing is certain. So many inquiries have been made at the City Hall here about the workings of it that our city engineer, Col. T. H. Tracy, has not time to answer them all, and has published the following pamphlet on the subject:

THE SEPTIC TANK.

The economical disposal of sewage is a problem which has engaged the attention of engineers and scientists for a great many years with varying results.

Sand filtration, sewage farming, chemical precipitation, bacterial filtration are the most notable processes tried and found wanting. The objection to each of these processes are briefly as follows:

Sand Filtration, continuous or intermittent.—The area of suitable sand ground required is usually difficult to obtain in the neighborhood of a city, and if obtainable the elevation or position is such as to necessitate pumping and consequent continuous expense.

Sewage Farming is growing into disuse for principally the same reasons.

Chemical Precipitation is expensive, both on account of the cost of the chemicals and handling and also the dealing with the "sludge" which is produced in excessive quantity. The effluent is also liable to become offensive.

Bacterial Filtration.—Considerable success has attended this method of treating sewage, but taken alone there are objections to it. In treating raw sewage the filters become clogged and require to be of considerable size and consequently expensive construction.

Septic Tanks.—The most effective method of treatment of sewage so far known is the Septic Tank, either used alone where the discharge is into salt water or where a high degree of purification is not necessary or in conjunction with bacterial filters where the effluent must be comparatively pure. The tanks are usually constructed of concrete, arched over and of a capacity equal to 18 to 24 hours' flow of sewage with a depth of about 5 feet, the inlet and outlet pipes being turned down to a depth of about 18 feet below the surface, so as to leave the scum, which forms on the surface, and in which the bacterial action is carried on, undisturbed. After the tank has been in use about a week a brown scum forms on the surface, which gradually increases, until the full action is attained. In this scum the action of what are known as anaerobic bacteria goes on, the greater part of the sewage being liquefied and a very small deposit resembling black ashes being deposited; that about 90 per cent. of the organic matter in suspension and about 30 per cent. of that in solution are removed and that the deposit does not require to be removed for several years. The practical result undoubtedly is that the offensive matter of the sewage is destroyed and the effluent is sufficiently clear for discharging into salt water or where a high degree of purification is not necessary.

Where discharged into a running stream or where greater purification is desirable a small bacterial filter or set of filters may be added. In such a case much smaller area of filter is necessary than if filters alone are used, as the effluent from the septic tank will go through at least four times as fast as the raw sewage, and the filter beds are not liable to be clogged.

The Vancouver Septic Tanks are three in number, designed for populations of 5000, 3000 and 2000, respectively, and were constructed in 1900 from plans furnished by the Septic Tank Syndicate, the first being put in operation about Jan. 1, 1901, and the others a month or two later. The results so far (August) are quite satisfactory, though the quantity of sewage passing through is not such as to make the conditions most favorable for the development of bacterial action. In one of the tanks near the Crematory the scavengers have been dumping night soil to the extent of five or six loads a night, and, though the last tank to be put in operation, the effluent is the clearest.

There have been no analyses yet made, either of the sewage or the effluent, but the practical effect of the bacterial action is very apparent. There is no smell from the tanks or the effluent. The earth has been filled over the tanks, leveled and seeded, so that the appearance of the surface is not unsightly or offensive in any way.

Some slight changes have been made in the plans furnished by the Syndicate; in order to avoid the use of wood covering for the inlet and effluent channels the concrete walls having been continued up and arched over, leaving only the necessary manholes appearing on the surface.

The above is a report I obtained to-day from our city engineer. Yours respectfully, W. J. McGuigan, M.D.

Value of Rest in Pulmonary Tuberculosis.

Colorado Springs, Colo., Sept. 13, 1901.

To the Editor:—A very interesting letter from Dr. Chas. Denison appears in the columns of The Journal, of August 31.

It seems to me, however, that he, as well as many others who speak of the treatment of pulmonary tuberculosis, voices a deeply-rooted error when he says in the concluding paragraph of his letter "they are all coming around to the same belief . . . *namely, pure air and an active* (italics mine) outdoor life in that climate where it can be had the easiest and most comfortably."

Having myself been the victim of pulmonary tuberculosis for more than seven years past and becoming thereby deeply interested in all that pertains to the therapeutics of this disease and watchful of all procedures for its amelioration in others as well, I feel that the subject of exercise in this condition ought to be settled without much difficulty. In no other form of tuberculosis is an active functionating of the part affected permissible. In tuberculosis of hip, knee, spine or any other joint, rest is of prime importance. In glandular tuberculosis anything like massage is contra-indicated, and who would be daring enough to advocate systematic thinking as a therapeutic measure in tubercular meningitis?

If once a clear conception of the difference necessary in outlining treatment for those predisposed to tuberculosis and those who already have it actively present is grasped, I believe the present haziness on the subject of exercise will disappear.

As a prophylactic measure in those who by reason of inheritance, environment or poor anatomic development are predisposed to pulmonary tuberculosis, exercise of the chest and lungs is of undoubted advantage. When, however, an active process is present in the lungs the quieter such organs can be kept the better.

Soft, weak muscles are made firmer and stronger by systematic exercise. If such muscles become the seat of an inflammatory action no sane physician would prescribe exercise in any form for them.

I fail to see why the analogy is not fairly applicable to the lungs. If the lungs are sluggish, the pulmonary breath sounds are feeble, especially if the chest is contracted and the family *history for pulmonary troubles is bad, by all means prescribe* graded and systematic pulmonary gymnastics; but, on the other hand, when tuberculosis has already started in the lungs let us follow the rational methods used for treating tuberculosis elsewhere, *by putting the lungs as nearly at rest as possible.* I am well aware that not infrequently but one lung is affected, and when this is the case pulmonary gymnastics, while benefiting and strengthening the healthy lung, damages the one that is diseased, and occasionally the benefit is greater than the detriment. I am, however, strongly of the opinion that generally in such cases *the evil exceeds the good.*

Full diet, fresh air, day and night, careful attention to the hygiene of skin and bowels, and rest, including a large amount of sleep (ten hours or more), with occasional counter-irritation to chest and otherwise symptomatic treatment when called for, sums up, it seems to me, what may be termed a safe basis for the treatment of pulmonary tuberculosis.

I may add that these are not merely theoretical considerations but are the results of observations on many afflicted, myself included. Truly yours, W. F. Martin, M.D.

A Use for Criminals.

Palmerston, Ontario, Sept. 20, 1901.

To the Editor:—President McKinley has been laid to rest and his assassin remains to be dealt with by the law as a nuisance to society. Before he is executed might he not be used for some useful purpose? Recent investigations in tuberculosis and cancer, two of the world's greatest scourges, have shown the necessity of the use of a human subject for further research. Already a physician has offered himself as a subject to test whether bovine tuberculosis is transmissible to man. The necessary experiments would not entail any great suffering on the criminal, and public opinion generally would be thoroughly in accord. I can see no objection to this use of desperate criminals. This practice was in vogue when Jenner introduced vaccination to the world, but in the nineteenth century seems to have fallen entirely into disuse. W. R.

Nerve Nostrums and Their Dangers.

Sonyea, N. Y., Sept. 21, 1901.

To the Editor:—The undersigned is preparing a paper on "Nerve Nostrums and Their Dangers," by request of Dr.

George F. Butler, Chairman of the Section on Materia Medica, Pharmacy and Therapeutics, of the American Medical Association, for the June, 1902, meeting, and would be glad to have physicians and others send him samples or literature of such nostrums coming under their notice, or tell him of them and where they may be procured.

Wm. P. Spratling, M.D.,
Craig Colony for Epileptics, Sonyea, N. Y.

Married.

George Mason Cheevy, M.D., to Miss Lucy Morris Ellsworth, both of New York, September 12, at New Hartford.

Emil Grasser, M.D., to Miss Bessie Clay, both of Louisville, last April.

Franklin Jerome Hall, M.D., Dallas, Tex., to Miss Rowen Mary Russell, Winchester, Mass., August 28.

John T. Hubel, M.D., to Miss Mary Engle, both of Detroit, Mich., September 2.

Lee Weber, M.D., Davenport, to Miss Annie Louisa Corner, Des Moines, Ia., September 12, at Des Moines.

William B. S. Richardson, M.D., to Miss Birdice Blye, both of Chicago, September 18.

Howard A. Ijams, M.D., to Miss Mae Armstrong, both of Knoxville, Tenn., September 12.

W. H. Jones, M.D., to Miss L. E. Griffitts, both of Unitia, Tenn., September 7.

Leroy W. King, M.D., to Miss Marion Allen, both of Lowville, N. Y., September 13.

George L. Marion, M.D., Elgin, Ill., to Miss Berg, Chicago, September 3, at the home of the bride.

Joseph A. Morris, M.D., Wilton, N. C., to Miss Lizzie Reid Martin, at Roanoke, Va., September 3.

Ernest S. Reedy, M.D., to Miss Josepha Mae Ator, both of Bloomington, Ill., September 5.

Jay G. Roberts, M.D., to Miss Louise Carnahan, both ot Hastings, Neb., September 4.

F. Conger Smith, M.D., New York, to Miss Kate Comstock, Topeka, Kan., September 3, at the home of the bride.

James E. Taylor, M.D., to Miss Martha J. Neal, both of Richmond, Ind., September 12.

E. Otis Smith, M.D., to Miss Eugenia Bradley, both of Cincinnati, September 4.

William Sidney Thayer, M.D., to Miss Susan C. Read, both of Baltimore, September 3.

George Halleck White, M.D., to Miss Harriett King Ricker, both of Rochester, N. Y., September 5.

Leopold Schiller, M.D., to Miss Charlotte Miller, both of Milwaukee, September 24, at the home of the bride.

Deaths and Obituaries.

William F. Holt, M.D., Jefferson Medical College, Philadelphia, 1857, who had gone to New York for medical treatment, died suddenly at that place, September 10, aged 65. He was born in Georgia, educated at the State University and had been in active practice at Macon for the last forty-four years, with the exception of the time he served as a surgeon in the Civil war. He was several times chosen president of the Georgia State Medical Association, having first been elected in 1882, and in 1890 was a delegate to the International Medical Association, which met at Paris that year. He was for ten years a member of the Board of Education, served for twenty-three years as physician for the Academy for the Blind, and was physician for the Methodist Orphans' Home for twenty-five years. He had served as chairman of the medical board of the City Hospital since its organization, and he was a member of the American Medical Association. The Macon Medical Society met and voted to attend the funeral in a body and to devote the next regular meeting to a memorial meeting in his honor.

Josias A. Ireland, M.D., Kentucky School of Medicine, 1851, died at his home in Louisville, September 20, from arteriosclerosis, aged 77. For the past fifty years, up to his retirement from active practice, he had been a prominent member of the medical profession in Louisville, having been president of the Mississippi Valley Medical Association in 1879, and one of the founders of the Louisville Medical College, of which he was dean and professor of gynecology for a number of years. He was also a member of the American Medical Association, American Public Health Association, and the Kentucky State and Medico-Chirurgical societies.

Benjamin M. Failor, M.D., Jefferson Medical College, Philadelphia, 1855, while returning from a night call, September 12, at Newton, Ia., where he had practiced for the past thirty-five years, was assaulted by robbers and died a few hours later as the result of his injuries. He was a native of Bucyrus, Ohio, and was a surgeon in an Ohio regiment during the Civil war. He was 76 years of age, and for a number of years had been Grand Surgeon of the Iowa department of the G. A. R.

R. Berrien Burroughs, M.D., Jefferson Medical College, Philadelphia, 1856, died, after a long illness, at Norfolk, Va., September 11, aged 68. He was born at Savannah, Ga., and educated at the University of Georgia. During the Civil war he served as surgeon in the 63d Georgia Infantry and the 4th Georgia Cavalry; at the time of his death he was chief surgeon of the Florida Division of the United Florida Veterans. At one time he was president and again vice-president of the Florida State Medical Association.

John K. Boude, M.D., University of Pennsylvania, Philadelphia, 1857, who for the past twenty years had been a member of the Board of Pension Appeals, died at Ocean Grove, N. J., September 8, aged 69. He was born and educated in Ohio, graduating from Miami University. He was an assistant surgeon of the 118th Illinois Infantry, having taken up practice at Carthage, Ill., and served through the Civil war with that regiment.

R. Bruce Wallace, M.D., Jefferson Medical College, Philadelphia, 1868, died suddenly at his home in Union, Neb., September 16. He was born in Missouri and moved to Union in 1887, after practicing for a time in Wyoming. He was a member of the Otoe County Medical Society, of which organization he was a number of times president.

Thomas A. Graham, M.D., Medical College of Ohio, Cincinnati, 1871, University of Louisville, 1872, died from Bright's disease at his home in Jeffersonville, Ind., September 14. He was a member of the Jeffersonville Board of Health, and at one time was a member of the Indiana legislature.

James W. Adams, M.D., University of Michigan, Ann Arbor, 1868, died at his home in Des Moines, Ia., September 13. He was born near Danville, Ind., and served with the 7th Indiana Infantry during the Civil war, enlisting as a private and being promoted to lieutenant.

Samuel C. Edmonds, M.D., University of Pennsylvania, Philadelphia, 1851, died at his home in Linwood, N. J., September 16, aged 72. He had practiced medicine along the coast in his county for the last fifty years.

W. T. Eignus, M.D., Rush Medical College, Chicago, 1901, who was a member of the staff of the State Insane Hospital, was drowned, September 19, by the capsizing of his skiff while hunting near Kankakee, Ill.

George W. Delap, M.D., Long Island College Hospital, New York, 1885, a deputy coroner of Brooklyn, N. Y., died at his home in that city, September 13.

Jacob Sell, M.D., Western Pennsylvania Medical College, Pittsburg, 1889, died from typhoid fever, September 10, at his home in Greensburg, Pa., aged 39.

Solomon G. Carpenter, M.D., University of the City of New York, 1845, died at his home in Chester, N. Y., September 13, aged 76.

Samuel W. McMahan, M.D., Medical College of Indiana, Indianapolis, 1879, died, after an illness of three months, at his home in Indianapolis, September 11, aged 55.

Nathaniel S. Cheeseman, M.D., Albany Medical College, 1860, died at his home in Scotia, N. Y., where he had practiced for the past thirty years, September 12, aged 67.

D. E. Newcomb, M.D., Detroit Medical College, 1885, died at his home in Carleton, Mich., September 16, as the result of a stroke of paralysis.

Charles E. Hollenback, M.D., Bellevue Hospital Medical College, New York, 1874, died at his home in Halsey Valley, N. Y., September 13, after a brief illness, aged 51.

Samuel M. Forrest, M.D., Medical Department of Washington University, St. Louis, 1877, died at his home in Renick, Mo., September 3, aged 57.

Henry A. Lamb, M.D., Vanderbilt University, Nashville, 1901, died at his home in Portland, Me., September 16, aged 24.

Book Notices.

The Medical Directory of New York, New Jersey and Connecticut. Volume III. Cloth. Pp. 914. Price, $2.50. Published by the New York State Medical-Association. 1901.

The third volume of this excellent Directory is not only fully equal to the two preceding issues, but seems to be even better. While the verification of the exactness of such a book is practically impossible, except by long use, the tests we have been able to make of it have shown that it is perfectly reliable. In this issue is incorporated the names of all legally registered physicians, without regard to school of practice, which, as we understand it, has not been the case with the former volumes. This is certainly commendable. One of the functions of the New York State Medical Association is the prosecution of illegal practitioners; hence, it is important to know who have the right to practice. According to the Directory, New York State has 10,112 physicians, New Jersey 1472, and Connecticut 1060. The arrangement of the book is different from that of former issues in that all the information pertaining to each state is grouped by itself and a distinctive colored paper is used for each, so that ready reference is easy. Brooklyn is made distinctive from New York City by yellow paper being used instead of white. This, as well as in everything that the Committee has done, seems to have been with the view of making the Directory not only reliable but practical in every way. A large amount of information is given in regard to societies, hospitals, medical colleges, etc. The medical laws of New York, New Jersey and Connecticut are given in full, as well as the names of the boards of examiners, Board of Regents, etc., and other information of value to all who are now members of the profession of the three states covered. Besides the list of physicians arranged alphabetically there is also a street list, a valuable but a laborious part to arrange, the summer residences of physicians who have them, etc. The book has been well gotten up and is a credit to the Committee of the New York State Medical Association, that must have worked indefatigably to accomplish the task it assumed when it undertook to get up a directory of the Empire State, as well as of the two adjoining smaller states. The Committee should be encouraged in its work in every way possible. Every physician in the states of New York, New Jersey and Connecticut certainly will be interested enough in the Directory to obtain a copy.

Epilepsy and Other Chronic Convulsive Diseases; Their Causes, Symptoms and Treatment. By Sir William R. Gowers, M.D., F.R.C.P., F.R.S., Consulting Physician to University College Hospital. Second Edition. Cloth. Pp. 320. Price, $3.00. Philadelphia: P. Blakiston's Son & Co. 1901.

The early edition of Gowers' work on epilepsy was a standard work and the present one will take its place, in all respects. The statistical basis for the more general facts of the disease have been greatly enlarged and a large amount of work has been done in revision and addition to the text. The author's well-known standing as a neurologist gives weight to whatever he may say. Nevertheless, one or two minor points may be mentioned; he repeats the time-honored statement that unconsciousness is an invariable attendant on major attacks, though there is considerable evidence extant that it may not be invariable, and he is guilty of a little inconsistency when he says later that little is known of the sensations that attend severe convulsions since the patient is almost always unconscious. Dr. Gowers considers that the spontaneous cure or cessation of attacks does sometimes occur and is probably of greater frequency than writers on the condition have usually admitted, but it is not sufficiently common to be recognized as a particular element in the prognosis. In this he apparently fails to consider a large number of cases where epilepsy is a merely accidental or temporary episode in the patient's life. There are many people who under certain stress have one or more epileptic attacks, which are never repeated and the number of such is, we think, rather greater than he seems to admit. Sometimes this cessation may be due to treatment, but sometimes it is spontaneous. He also seems to underrate the danger to life from epileptic fits, though he may possibly be correct in estimating the number of such accidents as small when taken in comparison with all cases of epilepsy. If the records of insane hospitals were studied it will be found that epilepsy is a very serious matter as regards the possibility of sudden death, and in all cases it seriously complicates conditions that might not be fatal without it. In the main, however, the work is one that can be safely followed and is perhaps one of the best monographs on this disease or symptom that exists.

Les Sourds-Muets en Norvege. La Surdi-Mutité, sa Distribution, ses Causes ses Symptoms. Son Rapport avec les Unions Consanguines, Conditions Sociales des Sourds-Muets; avec Remarques sur la Diagnose, la Prophylaxie et le Traitement de la Surdi-Mutite. Par V. Uchermann, Professeur à l'Université de Christiana. Publie par les soins de L'Etat. *Première partie (texte); et 2ième partie (annexe);* 116 Tableux, 2 Cartes, 1 Annexe (Cartes). Traduit du Norvegien Par Joahim Nicolaysen et Theophile Chauvin. Cloth. Pp. 550. Christiana: Alb. Cammermeyer, Editeur. 1901.

This is a most exhaustive study of deaf mutism in Norway covering the subject in all its possible relations, and discussing the theme with reference to nearly all the European literature of note on the subject. Norway would appear to afford a specially favorable field for such a study, not particularly on account of the frequency of this defect, but because of the peculiar distribution of a comparatively limited population in isolated communities often remote from routes of transportation and yet with reliable registration. The study is of especial interest therefore as giving a discussion of some questions of the etiology of deaf mutism, idiocy, etc., from data particularly adapted to throw light upon them. Among these are the questions of the effects of consanguinity of parents, which must be frequent in the isolated communities of Norway, and the effects of heredity generally in the production of these degeneracies. All these matters are very thoroughly discussed and the work will be an important one for reference on such facts. Every other etiologic factor seems also to have been taken up and judiciously handled, both as regards the analysis of the special statistics and their comparison with other data gathered elsewhere. Heredity and consanguinity, social conditions, syphilis, leprosy, age of parents, geology and climate, water supply, etc., are all considered and treated of at length. The work contains elaborate charts showing the distribution of deaf mutism, etc., in Norway, and in a supplementary volume what appears to be a complete list of the cases with a number of very interesting family trees showing the effects of heredity and intermarriage, etc. The work in its way is a monumental one that takes an important place in the literature of its subject, and in this French translation will widely extend its usefulness.

Hygiene and Public Health. By Louis Parkes, M.D., D.P.H., Lond. Univ., and Henry Kenwood, M.B., D.P.H., F.C.S., Fellows of the Sanitary Institute and Members of the Board of Examiners. With Illustrations. Cloth. Pp. 732. Price, $3.00 London: H. K. Lewis. Philadelphia: P. Blakiston's Son & Co. 1901.

This work appearing externally under the same title as the well known Parkes Hygiene so long before the profession, is really a new work under joint authorship in which the older one has been taken for a basis. The book is condensed in style and while specially adapted to English readers is nevertheless one that will be of value to students of hygiene in any part of the world. It has been written especially for English practitioners who are studying for the various public health diplomas, but its convenience as a reference book to others is not lessened thereby. The views of the authors on certain subjects, as for example, the use of alcohol, etc., are those that have been held in the past and not in all respects what modern reformers would advocate, that is to say they do not go to extremes. On the whole, the work will be found to be a very safe guide and a very handy reference book for the physician.

A Guide to the Clinical Examination of the Blood for Diagnostic Purposes. By Richard C. Cabot, M.D., with Colored Plates and Engravings. Fourth Revised Edition. Cloth. Pp. 494. Price, $3.25. New York: Wm. Wood & Co. 1901.

This fourth edition of Cabot's work has been almost entirely rewritten. The section on serum diagnosis has been abridged and the table of contents abbreviated so that the book is not greatly increased in size. It has apparently been brought up to date, though some of the very latest researches in regard to blood diagnosis do not appear to be mentioned. Like the former editions, it is handsomely presented to the profession and will undoubtedly retain the favor with which it has heretofore been received.

Societies.

COMING MEETINGS.

Utah State Medical Society, Provo City, Oct. 1-2, 1901.
Idaho State Medical Society, Pocatello, Oct. 3-4, 1901.
Tri-State Medical Society of Alabama, Georgia and Tennessee, Nashville, Tenn., Oct. 8-10, 1901.
Wyoming State Medical Society, Evanston, Oct. 8-9, 1901.
Vermont State Medical Society, Montpelier, Oct. 10-11, 1901.
New York State Medical Association, New York City, Oct. 21-24, 1901.
Medical Society of Virginia, Lynchburg, Nov. 5-7, 1901.
Oklahoma Territory Medical Association, Oklahoma City, Nov. 13, 1901.
Southern Surgical and Gynecological Association, Richmond, Va., Nov. 19, 1901.

Huntington County (Ind.) Medical Society.—This Society held its annual meeting at Huntington, September 17. Dr. Charles L. Wright was elected president, and Dr. Erwin Wright, secretary and treasurer, both of Huntington.

Louisville Society of Medicine.—At the annual meeting of this Society, held September 12, Dr. Walker B. Gosset was elected president; Dr. Thomas A. Hays, vice-president; Dr. Waller O. Green, secretary, and Dr. A. Henry Falconer, treasurer.

Knox County (Tenn.) Medical Society.—At the annual meeting of this Society, held at Knoxville, September 5, the following officers were elected: Dr. C. P. McNabb, president; Dr. J. M. Kennedy, vice-president; Dr. A. D. Scruggs, secretary; and Dr. E. R. Zemp, treasurer.

Syracuse (N. Y.) Hospital Association.—At a meeting of this Association, held at Syracuse, September 5, a permanent organization was effected and the following officers elected: President, Dr. Nathan Jacobson; vice-president, Dr. Frederick R. Hazard, and secretary-treasurer, Dr. George M. Price, all of Syracuse.

Douglas County (Minn.) Medical Society.—The annual meeting of this Society was held, August 4, and the following officers elected: Dr. Herbert J. Orchard, West Superior, president; Dr. A. W. James, Solon Springs, vice-president; Dr. Louis Moody, secretary, and Dr. P. G. McGill, treasurer, both of West Superior.

Montour County (Pa.) Medical Society.—At the annual meeting of this Society, held at Danville, September 4, the following officers were elected: President, Dr. T. B. Wintersteen; vice-presidents, Drs. G. A. Stock and E. A. Smith; corresponding secretary, Dr. Ida Ashenhurst; recording secretary, Dr. J. R. Kimerer, and treasurer, Dr. P. C. Newbaker.

International Congress of Nurses.—The week ending September 21 marked a very successful meeting of this Congress at the Pan-American Exposition. Saturday was set apart by the management as Nurses' Day, and the close was the occasion of a reception given at Castle Inn by the local nurses' societies. The attendance was good throughout the meeting and much interest was shown in the papers.

National Association of Hospital Superintendents.—At the meeting of this Association, held in New York City, September 12, the following were elected for the ensuing year: Dr. J. T. Duryea, Kings County Hospital, president; Dr. Charles O'Reilly, Toronto General Hospital, vice-president; A. D. Shaw, Harper Hospital, Detroit (re-elected), treasurer, and Dr. D. T. Test, Pennsylvania Hospital, Philadelphia, secretary.

American Academy of Railway Surgeons.—At the annual business meeting of the Academy, held in Chicago, September 13, the following officers were elected: Dr. August F. Jonas, Omaha, president; Drs. Luther Sexton, New Orleans, and William H. German, Morgan Park, Ill., vice-presidents; Dr. Thomas B. Lacey, Council Bluffs, secretary and treasurer, and Dr. R. Harvey Reed, Rock Springs, Wyo., editor. The Academy meets in 1902, at Kansas City, Mo.

Rockland County (N. Y.) Medical Association.—On September 6, at Hotel St. George, Nyack, N. Y., the members of the Fifth District Branch met and organized this Association, by the adoption of by-laws and the election of the following officers: President, Dr. George Blauvet, Nyack; vice-president, Dr. D. V. Van Wagenen, Suffren; secretary-treasurer, Dr. N. B. Bailey, Haverstraw; fellow, Dr. S. W. Toms, Nyack, and alternate, Dr. Charles D. Kline, New York. Addresses were made by Dr. John A. Wyeth, president of the New York State and the American Medical Associations; Dr. Edmond L. Cocks, secretary of the Fifth District Branch of the New York State Medical Association; Dr. C. E. Dennison, treasurer New York County Medical Association; Dr. J. W. S Gouley, New York City; Dr. Milton C. Conner, Middletown, and Dr. C. S. Payne, Liberty, president of the Sullivan County Medical Association. The enthusiasm of the members of the regular profession in the work of the New York State Medical Association in the county, is shown by the fact that of the twenty-four practicing physicians in the locality, eleven have already become members of the Association and eight of the others have signified their intentions of doing so at an early date.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Twenty-seventh Annual Meeting, held at Put-in-Bay Island, Ohio, September 12, 13 and 14, 1901.

President Dr. A. H. Cordier, Kansas City, Mo., in the Chair.

President's Address.

Dr. A. H. Cordier selected for his subject "Some Phases of Nephrolithiasis." He drew the following deductions: 1. Hemorrhage from parenchymatous organs is, in most instances, easily controlled. 2. Nephrolithiasis is more prevalent than is generally supposed. 3. A stone having formed in the pelvis of the kidney, if too large to pass through the ureter, will sooner or later produce symptoms demanding its removal. 4. Suppuration in stone cases is, as a rule, a late process and should be prevented by early surgery. 5. A wound in a healthy kidney heals rapidly. 6. Obscure, persistent pains in the region of the kidneys, in a patient who has had a renal colic years ago, should lead to an exploration of the kidney. 7. The operation of nephrolithotomy has a very low mortality. 8. The kidney should not be removed unless practically destroyed by the disease. 9. There exists a special cause for the development of stones in the right kidney. 10. With a carefully obtained clinical history, the diagnosis of stone in the kidney is usually easy. 11. At the time of operating the ureter should be explored, that its patency can be assured. 12. Post-operative patience and faithful effort on the part of the surgeon will result in the saving of many organs; otherwise removal will be necessary.

Fractures.

Dr. E. B. Smith, Detroit, read a paper on this subject. He gave a résumé of the old and new methods in diagnosing fractures. He said that fractures in each stage presented certain definite pathological surgical conditions. The diagnosis, treatment, prognosis, complications with their medico-legal status were dwelt upon at length, and lesions examined, treated, and met by surgical experience.

Dr. A. M. Hayden, Evansville, said a joint that has a fracture into it should be kept quiet or immobilized for at least four or five weeks, so that the fragments may become thoroughly united and healed before resorting to passive motion. Passive motion was used too early.

Dr. W. T. Stewart, Chicago, spoke of suturing the fragments in fractures, saying he had been disappointed in using the various methods recommended in text-books and journal literature, and expressed the hope that some member would speak of immobilization of parts in delayed union of fractures, and in fractures of recent occurrence.

Dr. S. S. Thorn, Toledo, said one cause of delayed union in fractures was malnutrition, the result of enforced anemia, and this anemia was the result of applying bandages too tightly and the use of short splints, thereby causing constriction, which resulted in anemia, starvation, and hence delayed union.

Dr. A. J. Ochsner, Chicago, mentioned the interposition of muscle or fascia between the fragments as another cause of non-union of bone, and cited cases in point.

Dr. A. M. Phelps, New York, spoke of a third reason why union did not take place after a fracture of the thigh—the nutrient artery became ruptured, and thus nutrition was cut off. Treating fracture with coaptation splints was wrong. He favored extension (Buck) and fixation in fractures of the femur. A patient with a fractured femur is put to bed with Buck's extension applied for a week or ten days, until laceration of the soft parts has subsided, after which a brace is applied, the patient gets out of bed, is driven about in a carriage, and fed well.

Floating Liver, with Report of a Case.

Dr. J. Henry Carstens, Detroit, said that very few such cases had been reported. The condition was often associated with general ptosis of the abdominal viscera. The patient was a woman, aged 40, quite stout. A gradually developing tumor had been noticed, starting on the right side and growing downwards. It was firm and non-fluctuating. On account of the distressing nervous symptoms, an exploratory celiotomy was done, and the right lobe of the liver found enlarged and hanging down to the pelvis. It could be replaced in the normal position, and was stitched there. Recovery took place, with disappearance of all the distressing symptoms.

Dr. Willis G. MacDonald, Albany, had seen a considerable group of such cases. Some years ago he showed the lobe of a floating liver with a gall-bladder and some gallstones. He had seen two cases in which there was general ptosis of the liver, one in which, by change of position of the patient, it was quite possible to have had the liver float down beyond the border-line of the umbilicus, and, changing the position of the patient back again, have it disappear beyond the border of the ribs.

Report on Sterilization of Rubber Gloves by Formaldehyde, and on the Use of Mild Antiseptics Inside the Gloves.

Dr. A. Goldspohn, Chicago, has carried on a series of bacteriologic tests to determine the minimum requirements for sterilizing rubber gloves by formalin gas. He used small pieces of surgeon's silk as germ-carriers, because the gas would evaporate from them. With his experiments he determined that, 1, a small connection with a chimney flue to afford a circulation of the gas in the sterilizer appears to be necessary when the gas is generated by a lamp; 2, that three hours was the minimum time needed for certain sterilization in his apparatus of that construction. A cross test was made by pouring culture material into the gloves afterwards, and heating it. Sterilized boric acid powder is used as dusting powder inside the gloves to make them slip on dry and very easily. About one-half ounce of 55 per cent. alcohol is then poured into each glove. The fluid in the gloves after operating one or more hours was tested by culture in many experiments and found sterile with one exception.

Infection from the Bacillus Aerogenes Capsulatus.

Dr. Julius H. Jacobson, Toledo, after detailing some experiments and narrating observations, deduced the following conclusions: 1. That infection from the bacillus aerogenes capsulatus occurs much more frequently than is recognized. 2. It dominates the whole field of pneumo-pathology (Welch). 3. Such terms as emphysematous gangrene, air embolism, emphysematous cellulitis, are misleading and vague, and should become obselete. 4. Infection from this germ produces a rapid toxemia; the formation of gas in infected areas resulting in gangrene and death. 5. Its principal habitat is the soil and intestinal tract. 6. Owing to its wide distribution in the soil, the danger of infection in all traumatic cases should not be forgotten. 7. A probable diagnosis can often be made by the history, clinical course, and objective signs of the case. 8. A positive diagnosis can only be made by bacteriologic examinations, cultural and animal inoculations. Simple stained specimens taken from the site of infection will often make the diagnosis.

Features Determining Permanency of Cure in Radical Operations for Hernia.

Dr. A. J. Ochsner, Chicago, said that the permanent success following herniotomy depended upon a comparatively small number of practical points which must be observed in order to secure satisfactory results regularly: 1. The wound must heal primarily because suppuration resulted in an abundance of cicatricial tissue and this was most unstable. 2. The stitches must not be drawn tightly, in order to avoid pressure necrosis. 3. The edges of the wound to be united must be free from fat and other unstable tissues. 4. The wound should be supported by broad rubber adhesive plaster strips until healed. 5. The patient should be kept in bed two or three weeks. 6. After the operation abnormal intra-abdominal pressure should be eliminated by avoiding constipation, etc.

1. In inguinal hernia the entire sac should be removed. *It was especially important to remove all the loose tissue between the transversalis and internal oblique muscles on one side and Poupart's ligament on the other.* The upper portion of this canal should be closed with especial care. In case of a long omentum this should be resected.

2. In femoral hernia the canal through which the sac protruded was a perfect ring and consequently if the entire sac was removed this ring would invariably close, and there could be no recurrence. All meddlesome operations contemplating the closure of this ring caused a certain percentage of recurrences.

3. In ventral hernia, following laparatomy, the original layers should be laid bare, and then the corresponding layers should be carefully united. The author preferred deep silkworm gut sutures to be tied after each layer had been united separately with chromicized catgut sutures.

4. In umbilical hernia the ingenious operation first described by Dr. W. J. Mayo, consisting of an overlapping of the edges of the hernial ring from above downward or from side to side for a distance of one and one-half inches, had given complete satisfaction.

Severing of the Vas Deferens and Its Relation to the Neuro-psychopathic Constitution.

Dr. H. C. Sharp, Jeffersonville, Ind., discussed the subject under three heads: 1. The law of heredity, influencing the formation of the character of intellect and will, and the controlling of the appetites and passions, and all the moral impulses, and the pathological conditions to which the mental and physical life are subject. The chief manifestations of this diathesis are chorea, hysteria, hypochondriasis, inebriety, imbecility, criminality, and insanity; and it includes in its subjects sometimes the most gifted, as Burns, Coleridge, Dr. Quincey, and others. 2. The rapid proportional increase of this diathesis, in the face of the efforts of noted sociologists and penologists. 3. The severing of the vas deferens as the means of stamping out this diathesis. The author outlined the field of the operation, the preparation for and method of operating.

Dr. A. J. Ochsner had removed the vas deferens in a number of tubercular cases since his first operative work on defectives and criminals, and in no case has there been any disturbance of the ability of the patient to enjoy sexual intercourse.

Morbid Conditions of the Upper Respiratory Tract Resulting from Infectious Diseases.

Dr. Carolus M. Cobb, Boston, gave a résumé of the autopsies reported by Wolff, Pearce and Zuckerkandl. These autopsies showed that the involvement of the nasal accessory sinuses during the course of the fatal cases of diphtheria, scarlet fever, measles, and influenza, was the rule rather than the exception. He then showed from an analysis of 102 cases of nasal or post-nasal catarrh without nasal obstruction, that 69 per cent. of these cases could be traced directly to one or more attacks of the infectious diseases. He called attention to the danger of treatment to the ears during the height of the primary disease, by means of douches, and drew the following conclusions:

Acute Intestinal Auto-Infection.

Dr. John M. Batten, Dowingstown, Pa., was called to see professionally W. F. B., 56 years, on Feb. 21, 1898. He had been suffering with exhaustion for several days, although neither his pulse nor his temperature was disturbed. He ordered him to bed, thinking that rest in bed might be beneficial to him. Within forty-eight hours, on his own account, patient took a dose of calomel, which still further prostrated him, so he had to be assisted to bed from the chamber. He noticed that patient had had a gray, leaden complexion for several weeks preceding his first call. That gray or cachetic complexion which was present is usually pathognomonic of intestinal auto-infection, although it may indicate malignant disease of the liver. In fact, it was his opinion it was malignant disease of the liver for several days after his first visit, before he could make a differential diagnosis of intestinal auto-infection from malignant disease of the liver, as there was a congestion or a thickening of the lower end of the stomach and upper end of the duodenum. The patient was corpulent, weighing 220 pounds, and lost 40 pounds during the two months he was confined to bed. Previous to his ailment, patient had been careless in securing a regularity in the movement of his bowels for some months. The usual symptoms presented themselves, constipation, flatulency, borborygmus, urates and the constituents of the bile in the urine, fever, headache, unpleasant dreams, and melancholia.

The treatment consisted of large daily doses of calomel till the bile flowed freely, then antiseptics internally, together with small doses of mercury, till an amelioration of the disease was effected, then the natural mineral waters, followed by vegetable tonics in connection with hot baths. For weak heart, with which he suffered, strychnia was prescribed. Nitrate of silver and small doses of mercury for the congestion of the lower end of the stomach, and upper end of the duodenum, which was thought to exist. The diet was beef essence, but he did not exhibit a disposition to eat. His legs swelled in convalescence, and he suffered acute pain alternately in the knees. Patient in due time fully recovered his health, after a protracted stay at Mount Clemens, Mich., whence he had gone as soon as he had convalesced sufficiently to enable him to do so.

Asthma.

Dr. John North, Toledo, Ohio, said that a great many theories have been advanced as to the etiology and pathology of asthma; among them may be mentioned reflex neurosis, contraction of bronchial tubes, nervous spasm, blood disease, irritation of air-tubes, irritating humors, extension of bronchitis, vasomotor bronchitis, diathetic neurosis, neuroses of the pulmonary plexus, uric acid diathesis, oxalic acid dyscrasia, excessive venous blood in the medulla, as a symptom of emphysema and bronchitis, etc. Most of these theories contain a small grain of truth, but no one of them can account for the asthmatic paroxysm. Three factors are required for the production of asthma. These are called the "asthmatic tripod," as follows: 1. A vulnerable area of mucous membrane. 2. An abnormally sensitive nerve center. 3. An external irritant or exciting cause. If all these three factors are present at any one time, we will have an attack of asthma. No two of them can produce an attack; all three are required. Remove one of them, and the attack of asthma will not return. The first factor for the production of asthma may be situated in the nose, naso-pharynx, pharynx, larynx, or bronchial tubes. The various names given to the different varieties of asthma are derived from the locality of the vulnerable area of mucous membrane. The second factor may be either inherited or acquired. The neurotic element in asthma has been observed by all writers. Uric acid, oxalic acid, and the oxalates may produce abnormal nerve centers. The third factor is difficult to determine in some cases, as we may have a number of irritants and exciting causes.

In the treatment of asthma, attention must be given to the three factors necessary to produce asthma. The treatment is divided into that of relieving the paroxysm of dyspnea, and treatment during the interval to prevent their recurrence. The relief of the paroxysm may be accomplished by remedies that relieve either of the three factors mentioned.

(To be continued.)

OMAHA MEDICAL SOCIETY.

Regular Meeting, held Sept. 11, 1901.

First Aid to the Injured.

Dr. August F. Jonas delivered an address on this subject. Dr. Jonas is the surgeon of the Union Pacific Railway and has been most fortunate in being permitted to carry out his ideas with reference to his department unhampered. He said that the proposition to establish classes for instruction in first aid work and to introduce the work over the whole system, was a business one, of advantage both to the company and the men. He was given carte blanche, and has been at liberty to do as he thought best.

It was Dr. Jonas' idea that the men must be instructed systematically, simply, and practically, and that interest in matters in first aid must be kept alive. To this end, classes were formed and models, charts and living subjects were used to teach the rudiments of anatomy. Very simple, plain English terms only were used. The pupils proved to be surprisingly apt. In a later lesson, shock, wounds, hemorrhage, burns and exposure to cold were considered. Still later, fractures, sprains, dislocations, suffocation and drowning were taken up. The next lesson covered fainting, apoplexy, intoxication, heat-stroke, epilepsy, concussion and poisons. Lastly, bandaging and transportation of the injured were taken up. The men were impressed with the idea that this instruction did not make them doctors and that the function of the first-aid man was to render intelligent assistance prior to the coming of the physician and that the uninstructed, though well meaning, who tried to assist the injured, often did things which were both useless and positively harmful. They were taught as strongly what not to do as they were what to do. Esmarch's triangular bandage was shown and used with surprisingly good results. The classes were shown how to use very simple splint material to prevent simple fractures from becoming compound. The use of simple, domestic remedies was taught. Each pupil was required to dress imaginary wounds and burns, to apply splints, bandages and the tourniquet, and to perform artificial respiration. Transportation of the injured, with and without stretchers, was practically taught. The interest manifested by the pupils was most flattering. They very quickly recognized any mistakes made in applying dressings. The pupils were all furnished with a copy of the "Manual of First Aid to the Injured," by Bowditch Morton, M.D. To maintain the interest, a "first-aid fraternity," composed of members who have passed an examination for the emergency corps, will be organized. The fraternity will have a ritual and will be officered by the men themselves. Dr. Jonas said that he was most gratified to know that the mass of the men had already learned not to put their fingers into a wound.

After a great deal of experimentation, he had placed in the various shops and upon all railway trains a tin box of first-aid supplies. These boxes are about 10 by 12 and 4 inches deep. They have four partitions of binder's board which can be used for small splints. The box contains antiseptic tablets, antiseptic pads, cotton, picric acid gauze, adhesive plaster, court four or five weeks, so that the fragments may become thoroughly united and healed before resorting to passive motion. Passive motion was used too early.

Dr. W. T. Stewart, Chicago, spoke of suturing the fragments in fractures, saying he had been disappointed in using the various methods recommended in text-books and journal literature, and expressed the hope that some member would speak of immobilization of parts in delayed union of fractures, and in fractures of recent occurrence.

Dr. S. S. Thorn, Toledo, said one cause of delayed union in fractures was malnutrition, the result of enforced anemia, and this anemia was the result of applying bandages too tightly and the use of short splints, thereby causing constriction, which resulted in anemia, starvation, and hence delayed union.

Dr. A. J. Ochsner, Chicago, mentioned the interposition of muscle or fascia between the fragments as another cause of non-union of bone, and cited cases in point.

Dr. A. M. Phelps, New York, spoke of a third reason why union did not take place after a fracture of the thigh—the nutrient artery became ruptured, and thus nutrition was cut off. Treating fracture with coaptation splints was wrong. He favored extension (Buck) and fixation in fractures of the femur. A patient with a fractured femur is put to bed with Buck's extension applied for a week or ten days, until laceration of the soft parts has subsided, after which a brace is applied, the patient gets out of bed, is driven about in a carriage, and fed well.

Floating Liver, with Report of a Case.

Dr. J. Henry Carstens, Detroit, said that very few such cases had been reported. The condition was often associated with general ptosis of the abdominal viscera. The patient was a woman, aged 40, quite stout. A gradually developing tumor had been noticed, starting on the right side and growing downwards. It was firm and non-fluctuating. On account of the distressing nervous symptoms, an exploratory celiotomy was done, and the right lobe of the liver found enlarged and hanging down to the pelvis. It could be replaced in the normal position, and was stitched there. Recovery took place, with disappearance of all the distressing symptoms.

Dr. Willis G. MacDonald, Albany, had seen a considerable group of such cases. Some years ago he showed the lobe of a floating liver with a gall-bladder and some gallstones. He had seen two cases in which there was general ptosis of the liver, one in which, by change of position of the patient, it was quite possible to have had the liver float down beyond the border-line of the umbilicus, and, changing the position of the patient back again, have it disappear beyond the border of the ribs.

Report on Sterilization of Rubber Gloves by Formaldehyde, and on the Use of Mild Antiseptics Inside the Gloves.

Dr. A. Goldspohn, Chicago, has carried on a series of bacteriologic tests to determine the minimum requirements for sterilizing rubber gloves by formalin gas. He used small pieces of surgeon's silk as germ-carriers, because the gas would evaporate from them. With his experiments he determined that, 1, a small connection with a chimney flue to afford a circulation of the gas in the sterilizer appears to be necessary when the gas is generated by a lamp; 2, that three hours was the minimum time needed for certain sterilization in his apparatus of that construction. A cross test was made by pouring culture material into the gloves afterwards, and heating it. Sterilized boric acid powder is used as dusting powder inside the gloves to make them slip on dry and very easily. About one-half ounce of 55 per cent. alcohol is then poured into each glove. The fluid in the gloves after operating one or more hours was tested by culture in many experiments and found sterile with one exception.

Infection from the Bacillus Aerogenes Capsulatus.

Dr. Julius H. Jacobson, Toledo, after detailing some experiments and narrating observations, deduced the following conclusions: 1. That infection from the bacillus aerogenes capsulatus occurs much more frequently than is recognized. 2. It dominates the whole field of pneumo-pathology (Welch). 3. Such terms as emphysematous gangrene, air embolism, emphysematous cellulitis, are misleading and vague, and should become obselete. 4. Infection from this germ produces a rapid toxemia; the formation of gas in infected areas resulting in gangrene and death. 5. Its principal habitat is the soil and intestinal tract. 6. Owing to its wide distribution in the soil, the danger of infection in all traumatic cases should not be forgotten. 7. A probable diagnosis can often be made by the history, clinical course, and objective signs of the case. 8. A positive diagnosis can only be made by bacteriologic examinations, cultural and animal inoculations. Simple stained specimens taken from the site of infection will often make the diagnosis.

Features Determining Permanency of Cure in Radical Operations for Hernia.

Dr. A. J. Ochsner, Chicago, said that the permanent success following herniotomy depended upon a comparatively small number of practical points which must be observed in order to secure satisfactory results regularly: 1. The wound must heal primarily because suppuration resulted in an abundance of cicatricial tissue and this was most unstable. 2. The stitches must not be drawn tightly, in order to avoid pressure necrosis. 3. The edges of the wound to be united must be free from fat and other unstable tissues. 4. The wound should be supported by broad rubber adhesive plaster strips until healed. 5. The patient should be kept in bed two or three weeks. 6. *After the operation abnormal intra-abdominal pressure should be eliminated by avoiding constipation, etc.*

1. In inguinal hernia the entire sac should be removed. It was especially important to remove all the loose tissue between the transversalis and internal oblique muscles on one side and Poupart's ligament on the other. The upper portion of this canal should be closed with especial care. In case of a *long omentum this should be resected.*

2. In femoral hernia the canal through which the sac protruded was a perfect ring and consequently if the entire sac was removed this ring would invariably close, and there could be no recurrence. All meddlesome operations contemplating the closure of this ring caused a certain percentage of recurrences.

3. In ventral hernia, following laparatomy, the original layers should be laid bare, and then the corresponding layers should be carefully united. The author preferred deep silkworm gut sutures to be tied after each layer had been united separately with chromicized catgut sutures.

4. In umbilical hernia the ingenious operation first described by Dr. W. J. Mayo, consisting of an overlapping of the edges of the hernial ring from above downward or from side to side for a distance of one and one-half inches, had given complete satisfaction.

Severing of the Vas Deferens and Its Relation to the Neuro-psychopathic Constitution.

Dr. H. C. Sharp, Jeffersonville, Ind., discussed the subject under three heads: 1. The law of heredity, influencing the formation of the character of intellect and will, and the controlling of the appetites and passions, and all the moral impulses, and the pathological conditions to which the mental and physical life are subject. The chief manifestations of this diathesis are chorea, hysteria, hypochondriasis, inebriety, imbecility, criminality, and insanity; and it includes in its subjects sometimes the most gifted, as Burns, Coleridge, Dr. Quincey, and others. 2. The rapid proportional increase of this diathesis, in the face of the efforts of noted sociologists and penologists. 3. The severing of the vas deferens as the means of stamping out this diathesis. The author outlined the field of the operation, the preparation for and method of operating.

Dr. A. J. Ochsner had removed the vas deferens in a number of tubercular cases since his first operative work on defectives and criminals, and in no case has there been any disturbance of the ability of the patient to enjoy sexual intercourse.

Morbid Conditions of the Upper Respiratory Tract Resulting from Infectious Diseases.

Dr. Carolus M. Cobb, Boston, gave a résumé of the autopsies reported by Woffl, Pearce and Zuckerkandl. These autopsies showed that the involvement of the nasal accessory sinuses during the course of the fatal cases of diphtheria, scarlet fever, measles, and influenza, was the rule rather than the exception. He then showed from an analysis of 102 cases of nasal or post-nasal catarrh without nasal obstruction, that 69 per cent. of these cases could be traced directly to one or more attacks of the infectious diseases. He called attention to the danger of treatment to the ears during the height of the primary disease, by means of douches, and drew the following conclusions:

Acute Intestinal Auto-Infection.

Dr. John M. Batten, Dowingstown, Pa., was called to see professionally W. F. B., 56 years, on Feb. 21, 1898. He had been suffering with exhaustion for several days, although neither his pulse nor his temperature was disturbed. He ordered him to bed, thinking that rest in bed might be beneficial to him. Within forty-eight hours, on his own account, patient took a dose of calomel, which still further prostrated him, so he had to be assisted to bed from the chamber. He noticed that patient had had a gray, leaden complexion for several weeks preceding his first call. That gray or cachetic complexion which was present is usually pathognomonic of intestinal auto-infection, although it may indicate malignant disease of the liver. In fact, it was his opinion it was malignant disease of the liver for several days after his first visit, before he could make a differential diagnosis of intestinal auto-infection from malignant disease of the liver, as there was a congestion or a thickening of the lower end of the stomach and upper end of the duodenum. The patient was corpulent, weighing 220 pounds, and lost 40 pounds during the two months he was confined to bed. Previous to his ailment, patient had been careless in securing a regularity in the movement of his bowels for some months. The usual symptoms presented themselves, constipation, flatulency, borborygmus, urates and the constituents of the bile in the urine, fever, headache, unpleasant dreams, and melancholia.

The treatment consisted of large daily doses of calomel till the bile flowed freely, then antiseptics internally, together with small doses of mercury, till an amelioration of the disease was effected, then the natural mineral waters, followed by vegetable tonics in connection with hot baths. For weak heart, with which he suffered, strychnia was prescribed. Nitrate of silver and small doses of mercury for the congestion of the lower end of the stomach, and upper end of the duodenum, which was thought to exist. The diet was beef essence, but he did not exhibit a disposition to eat. His legs swelled in convalescence, and he suffered acute pain alternately in the knees. Patient in due time fully recovered his health, after a protracted stay at Mount Clemens, Mich., whence he had gone as soon as he had convalesced sufficiently to enable him to do so.

Asthma.

Dr. John North, Toledo, Ohio, said that a great many theories have been advanced as to the etiology and pathology of asthma; among them may be mentioned reflex neurosis, contraction of bronchial tubes, nervous spasm, blood disease, irritation of air-tubes, irritating humors, extension of bronchitis, vasomotor bronchitis, diathetic neurosis, neuroses of the pulmonary plexus, uric acid diathesis, oxalic acid dyscrasia, excessive venous blood in the medulla, as a symptom of emphysema and bronchitis, etc. Most of these theories contain a small grain of truth, but no one of them can account for the asthmatic paroxysm. Three factors are required for the production of asthma. These are called the "asthmatic tripod," as follows: 1. A vulnerable area of mucous membrane. 2. An abnormally sensitive nerve center. 3. An external irritant or exciting cause. If all these three factors are present at any one time, we will have an attack of asthma. No two of them can produce an attack; all three are required. Remove one of them, and the attack of asthma will not return. The first factor for the production of asthma may be situated in the nose, naso-pharynx, pharynx, larynx, or bronchial tubes. The various names given to the different varieties of asthma are derived from the locality of the vulnerable area of mucous membrane. The second factor may be either inherited or acquired. The neurotic element in asthma has been observed by all writers. Uric acid, oxalic acid, and the oxalates may produce abnormal nerve centers. The third factor is difficult to determine in some cases, as we may have a number of irritants and exciting causes.

In the treatment of asthma, attention must be given to the three factors necessary to produce asthma. The treatment is divided into that of relieving the paroxysm of dyspnea, and treatment during the interval to prevent their recurrence. The relief of the paroxysm may be accomplished by remedies that relieve either of the three factors mentioned.

(To be continued.)

OMAHA MEDICAL SOCIETY.

Regular Meeting, held Sept. 11, 1901.

First Aid to the Injured.

Dr. August F. Jonas delivered an address on this subject. Dr. Jonas is the surgeon of the Union Pacific Railway and has been most fortunate in being permitted to carry out his ideas with reference to his department unhampered. He said that the proposition to establish classes for instruction in first aid work and to introduce the work over the whole system, was a business one, of advantage both to the company and the men. He was given carte blanche, and has been at liberty to do as he thought best.

It was Dr. Jonas' idea that the men must be instructed systematically, simply, and practically, and that interest in matters in first aid must be kept alive. To this end, classes were formed and models, charts and living subjects were used to teach the rudiments of anatomy. Very simple, plain English terms only were used. The pupils proved to be surprisingly apt. In a later lesson, shock, wounds, hemorrhage, burns and exposure to cold were considered. Still later, fractures, sprains, dislocations, suffocation and drowning were taken up. The next lesson covered fainting, apoplexy, intoxication, heat-stroke, epilepsy, concussion and poisons. Lastly, bandaging and transportation of the injured were taken up. The men were impressed with the idea that this instruction did not make them doctors and that the function of the first-aid man was to render intelligent assistance prior to the coming of the physician and that the uninstructed, though well meaning, who tried to assist the injured, often did things which were both useless and positively harmful. They were taught as strongly what not to do as they were what to do. Esmarch's triangular bandage was shown and used with surprisingly good results. The classes were shown how to use very simple splint material to prevent simple fractures from becoming compound. The use of simple, domestic remedies was taught. Each pupil was required to dress imaginary wounds and burns, to apply splints, bandages and the tourniquet, and to perform artificial respiration. Transportation of the injured, with and without stretchers, was practically taught. The interest manifested by the pupils was most flattering. They very quickly recognized any mistakes made in applying dressings. The pupils were all furnished with a copy of the "Manual of First Aid to the Injured," by Bowditch Morton, M.D. To maintain the interest, a "first-aid fraternity," composed of members who have passed an examination for the emergency corps, will be organized. The fraternity will have a ritual and will be officered by the men themselves. Dr. Jonas said that he was most gratified to know that the mass of the men had already learned not to put their fingers into a wound.

After a great deal of experimentation, he had placed in the various shops and upon all railway trains a tin box of first-aid supplies. These boxes are about 10 by 12 and 4 inches deep. They have four partitions of binder's board which can be used for small splints. The box contains antiseptic tablets, antiseptic pads, cotton, picric acid gauze, adhesive plaster, court plaster, vaselin, dusting powder, pins, safety pins, assorted roller bandages, a roll of cotton cloth, one of absorbent lint, rubber bandage and a pair of scissors. Simple directions for the use of the material in the box and directions as to how to treat such emergencies as fainting are enclosed within.

ROCKY MOUNTAIN INTERSTATE MEDICAL ASSOCIATION.

Third Annual Meeting, held at Denver, Sept. 3 and 4, 1901.

Retinal Lesions of Chronic Interstitial Nephritis.

Dr. Edward Jackson, Denver, divided the lesions into the following, 1, alterations in contour, size, color of the retinal vessels; 2, hemorrhage; 3, retinal edema; 4, degenerative changes in the neural elements of the retina and alterations in the layer of pigment epithelium; 5, deposits of exudate. These retinal changes are closely associated with vascular changes, and are more constant than with albumin in urine, casts of any form or any other clinical evidence of renal disease. They appear when the balance of blood pressure and matter to be eliminated has been lost, and give most positive notice of a state of nutrition that can not very long continue.

Changes Necessary to Secure Interstate Medical Licenses.

Dr. John A. Donovan, Butte, Montana, after reviewing the laws of the ten Western States, arrives at the conclusion that each state should amend its laws so as to accept certificates of certain other states. He does not agree with those who insist on the state making the educational requirements necessary to enter college.

Carcinoma of the Breast.

Dr. D. A. Richardson, Denver, analyzing the cases of carcinoma of breasts which he encountered during his twelve years of practice, noticed the following: That etiologically it is always of traumatic origin. He removed a sarcoma from a child 8 years old. If a carcinoma be let alone it becomes localized, and in many cases sacculated.

Conservative Surgery of the Ovary and Tube.

Dr. W. W. Grant, Denver, related a case and concluded that the ordinary benign cysts of the ovary should be treated by resection, and not by complete extirpation of the organ. The small healthy remnant of an ovary with an intact tube will carry on the functions of ovulation and menstruation normally.

Report of a Case of Acute Gangrenous Pancreatitis.

Dr. Leonard Freeman, Denver, said that the patient, Italian, 30 years, in good health until very recently, was seized suddenly with severe griping pain in abdomen, vomiting and diarrhea supervened. There were no chills, no headache; the abdomen was greatly distended, mind clear. Liver dulness was diminished, splenic dulness enlarged. There was some jaundice; pulse 100, temperature 101. In the left iliac region a dull resisting, somewhat prominent mass could be felt. An incision in the left iliac region revealed the presence of nearly a pint of bloody, foul-smelling, non-purulent fluid. The condition of the patient precluded further exploration. The autopsy showed a friable, disintegrated, greatly enlarged and gangrenous pancreas.

Report of Seventy Cases of Lobar Pneumonia.

Dr. J. N. Hall, Denver, gave the conclusion derived from a study of cases seen between September 1, 1900, and April, 1901. Deaths were 24, or 34.8 per cent. Eight cases died within twenty-four hours after admission to hospital. Of the 3 in the 1st decade of life all recovered; of the 16 in the 2d decade, 5 died; of the 13 in the 4th decade 6 died. Total number of lobes involved were 116. Other diseases associated were tuberculosis, 7; typhoid, 3; erysipelas, 1; general sepsis, 1; acute rheumatism, 1; cerebral thrombosi, 1; traumatic pneumothorax, 1; Bright's disease, 2; advanced empyema, 1; organic mitral regurgitation, 2. Highest temperature was 106. Venesection should be oftener employed. Sinapisms and turpentine stupes were used, as also ice. No medicinal antipyretics were used. Alcohol was freely used. He believes in the usefulness of strychnin.

Chemical Treatment of Traumatism.

Dr. R. Harvey Reed, Rock Springs, Wyo., said that peroxid of hydrogen was valuable in this condition: 1, as a hemostatic in oozing wounds; 2, to wash out pus and pathogenic microbes; 3, to diagnosticate and locate the extent of sinuses. He gives preference to moist dressings for the following reasons: Cell proliferation does not take place when the parts are dry. Dusting bodies collect in chunks and become foreign bodies.

Mountain Fever.

Dr. W. W. Woodring, Mt. Pleasant, Utah, takes the stand that there is such a thing as mountain fever. It is mostly confined to the young. He has never seen a case in a man over 50 years of age. It is ushered in with chill and followed by a temperature of from one to four degrees in the first twenty-four hours.

Report of Two Unusual Cases of Multiple Neuritis in Children.

Dr. E. Delehanty, Denver, reported a case in a boy who developed chorea after an attack of typhoid fever. Sometime after he recovered from the chorea he complained of pains in feet and hands, tingling sensation with feelings of pins and needles, wrist drop, foot drop, anesthesia of fingers and toes, wasting of extensors. Breathing later became difficult and diaphragmatic. Patient died. The other case was a boy of 9 years. After an attack of diphtheria he commenced to complain of numbness and tingling, double vision, wasting, foot drop, paralysis of soft palate. Death occurred.

The Function of the Appendix.

Dr. E. P. Hershey, Denver, said that the appendix has a secretory function. Whether or not this function is of any importance remains to be ferreted out by further investigation. Impaction occurs in transverse colon, sigmoid and rectum. But as soon as the appendix becomes affected impaction occurs at the cecum. This cul-de-sac is the most inviting place for the accumulation of feces. The mass remains here and would become hardened were it not for the secretions that keep the mass thin and moist. It is fair to presume that inasmuch as the appendix in the vast majority of cases is found pointing upwards, backwards and slightly to the left that this is its normal position. These statements have become facts through observation of a number of cases that have had the appendix removed. Whenever constipation occurs in these cases a sense of heaviness and oppression occurs in the right iliac fossa, invariably relieved by free purgation.

Dr. Wright said that he hoped the doctor had weighed the matter thoroughly before presenting a paper of this kind to the Society.

Dr. Edson thought the author had produced in his argument no facts with which to prove his position. It is logical, and a very pretty piece of argument, but he has given us nothing upon which to base it. We have his conclusions but he has produced no facts with which to substantiate his position, and his argument does not take into account the known pathology of appendicitis, and he has advanced a new idea as to the position of the appendix.

Dr. Beggs: The Doctor states that the appendix has a legitimate function in the human being upon its anatomic structure—upon the claim that the appendix has a much larger glandular supply than any other portion of the intestines. Now, with reference to that, we are met in the beginning with a little confusion of ideas. Histologically, the mucous membrane of the appendix is almost the same as that of the large intestine. The structure of the tubular glands in the appendix is the same as that in the large intestine. They are so infinitesimally smaller in man when compared with the rest of the intestine that from a quantitive point of view they can be neglected. When we pass a little lower in the scale of animals we find that the appendix plays a much greater function in the lower animals than in man. The so-called valve of the appendix does not act as an obstruction to foreign bodies in their passage into the appendix, and we must not offer our ideas that a majority of our cases are due to foreign bodies.

Dr. Perkins' experience had been that quite a large percentage of appendicitis cases begin with diarrhea, and not with a constipation. Another point is that in opening the abdomen for other operations we find the appendix in a normal condition, and it appears to have practically nothing in it, and it is very small as a rule, sometimes appears to be almost obliterated in portions, and it seems if the secretory object of this kind was so great as the writer would lead us to believe that we would find it distended with fluid, and find much more evidence of this sort of thing.

Dr. Eskridge moved that Dr. Hershey be requested to give this Association at its next meeting the data on which he bases his conclusions after having pursued his investigations farther. The motion was carried.

Report of a Case of Rapid Respiration in Fatal Organic Diseases of the Brain.

Dr. J. T. Eskridge, Denver, reported at length a case of exceedingly rapid and very slow respiration, with pauses in respiration varying from twenty seconds to two minutes in duration, in a patient suffering from tubercular meningitis, syphilitic periarteritis of the pons and medulla, and from hysteria. The most rapid respiration was 140 to 142 per minute; the slowest 2 to 3 per minute, the latter extending over prolonged periods.

An Operation for Spina Bifida.

Dr. Leonard Freeman, Denver, reported a case of a baby 7 weeks old who had a spina bifida, a translucent tumor the size of a goose-egg. The sessile sac had steadily increased in size until the integument had become translucent and as thin as tissue paper. An elliptical incision was carried around the tumor near the base and the sac opened. The elongated conus was freed from its ventral attachments to the sac and replaced within the opening. The sac was cut away near its base, neck freed from its attachments to edge of cavity and stuffed into opening on to cord. The operation was whipped over with silver wire, and wound sealed with collodion. Satisfactory recovery took place.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Fourteenth Annual Meeting, held at Cleveland, Sept. 17, 18 and 19, 1901.

FIRST DAY—MORNING SESSION.

President Dr. W. E. B. Davis, of Birmingham, Alabama, in the chair.

An Address of Welcome was delivered by Dr. C. H. Hoover, of Cleveland, to which a fitting response was made by President Davis.

Tubo-Abdominal Pregnancy.

Dr. William H. Humiston, Cleveland, reported this case. The principal points of interest were: 1. Extreme loss of blood and shock; pulse, 180, barely perceptible over radials; temperature, 95. 2. The prompt result of submammary injections of normal sterile saline solution at the time of beginning anesthesia. These injections were recommended in desperate cases. 3. No attempt was made to remove the large amount of blood filling the abdomen close to the pelvic brim. The large amount of blood gave no trouble, and was taken care of and absorbed by the peritoneum rapidly.

Cornual Pregnancy; Rupture in the Fourth Month; Operation; Recovery.

Dr. Miles F. Porter, Fort Wayne, Ind., saw Mrs. H. sixteen hours after she had been taken sick with severe abdominal pain accompanied by the usual signs of severe hemorrhage. She had had one living child and one miscarriage, and was near the middle of her third pregnancy. Hasty examination revealed nothing abnormal in the vagina save a slight bloody discharge. Celiotomy was immediately done and a ruptured cornual pregnancy of about four and a half months with bicornute uterus found. The belly was filled with blood. The ruptured cornu was amputated and the stump sutured, leaving the ovary and the tube attached to the stump. There was profound depression, which was treated by saline rectal injections, and hypodermic administration of digitalin and strychnin. Recovery was uneventful. A large quantity of warm sterile water was left in the abdomen. The intact cornu was much enlarged and attached to the ruptured cornu with a rather long pedicle. The gestation sac was thick save at the point of rupture and composed of uterine tissue. There was no communication between either the sac and the vagina or the tube and the sac. These communications became occluded subsequent to the impregnation. A decidual membrane was present. The presence of this membrane marks the case as one of ruptured pregnancy in an illy-developed cornu of a bicornute uterus. In tubal and interstitial pregnancy there is no decidual membrane in the sac. An abnormally low implantation of the tube and round ligament accounts for the fact that in this case they were attached to the outer side of the stump left after removal of the sac, and not to the sac itself, as is the rule. As a rule, pregnancy in a bicornute uterus terminates normally. In three of the cases referred to in the author's paper, including the author's, normal pregnancies preceded the rupture four times. In the others, no reference as to the other pregnancies was made. He had been able to find reports of but 18 cases of ruptured cornual pregnancy which, with his own, makes 19 cases reported to date. The symptoms are those of ectopic pregnancy save that the rupture occurs later in cornual pregnancy, and the hemorrhage is usually more profuse. A previous history of sterility or of tubal infection points to tubal rather than cornual pregnancy. These two papers were discussed jointly.

Dr. Edward J. Ill, Newark, N. J., endorsed the treatment employed by Dr. Humiston in his case, and said the quicker an operation is done in such cases, and the sooner the abdominal cavity is walled off, the better the chances for recovery of the patient. He agreed with Dr. Humiston as to the quantity of normal salt solution that these patients will receive and absorb. Massage assisted materially in the absorption of the fluid.

Dr. Edwin Walker, Evansville, Ind., referred to the indications for the use of normal salt solution in the abdominal cavity. He could not see what benefit was derived from the use of normal salt solution in the case of Dr. Humiston, for the reason there were well-organized clots, and these could not have been affected by it. Such clots, when organized, became drier and were absorbed, and the salt solution only aided in the absorption of any septic material that might be present. He believed it was a mistake in all cases to wash out the abdominal cavity with salt solution. By wiping out the cavity with dry gauze it could be made clean, if it was not infected.

Dr. M. Rosenwasser, Cleveland, commended the use of subcutaneous saline solution in the case of Dr. Humiston, but expressed doubt as to the value of salt solution in the abdominal cavity. He had not seen any special beneficial change either in the pulse or condition of the patient by leaving saline solution in the abdominal cavity. In packing the extraperitoneal cavity that was left, he used sterile gauze instead of iodoform gauze.

Dr. Herman E. Hayd, Buffalo, disagreed with Dr. Rosenwasser that the saline fluid was not absorbed. He had filled the peritoneal cavity with normal salt solution, leaving two stitches open, and in an hour and a half the fluid was absorbed, as subsequently verified by postmortem examination.

Dr. Rosenwasser did not wish to be understood as saying that the fluid was not absorbed, but that it was not readily absorbed when the peritoneum was in a pathological state.

Dr. J. Henry Carstens, Detroit, stated that the use of normal saline solution in the abdominal cavity prevented, to a large extent, agglutination of the intestines and omentum. This cavity could be cleaned out just as effectively by sponges as by washing it out with salt solution. The drier the cavity was kept, the better the chances for agglutination. He preferred the use of sterile rather than iodoform gauze.

Dr. James F. Baldwin, Columbus, Ohio, said he had been disappointed in the use of normal salt solution, whether injected into the subcutaneous tissue or poured into the abdominal cavity and left there to be absorbed. He had used salt solution again and again, and it seemed to him absolutely inert. He had never seen it produce a particle of benefit.

Dr. Charles Greene Cumston, Boston, stated that given a condition a patient was in when an operation was undertaken for ruptured tubal pregnancy, he did not think the peritoneal cavity nor the subcutaneous cellular tissue had a sufficient degree of vitality to be able to absorb the salt solution in the majority of cases. Furthermore, in cases where the surgeon injected salt solution into a cavity whose walls were the result of a pathologic change, he did not believe that the walls of that cavity would absorb the liquid. The only value that he could see in the normal salt solution was after a prolonged intra-abdominal operation, where the intestines had been exposed, where the loss of heat had been great and the surgeon desired to introduce a certain amount of heat into the abdominal cavity. On the other hand, the use of gauze sponges in wiping out the debris should be extremely limited because gauze would remove the epithelial covering of the peritoneum of the intestine and of the parietal peritoneum, and he believed was a fertile cause for adhesions after operation.

Dr. Edwin Ricketts expressed great disappointment in the use of normal salt solution. He believed the results of its subcutaneous use had been overestimated. Wiping out the abdominal cavity vigorously with a sponge was disastrous to the patient. Gauze should be pressed in and out without any marked friction of the peritoneum. No remedy had as yet been found equal to the judicious use of strychnin to overcome shock.

Dr. Humiston, in reply, said the abdominal cavity in his case was almost completely filled up to the under border of the liver with blood, and if he had attempted to handle the intestines and delay operation for the length of time it would take to cleanse the abdominal cavity of blood, he believed he would have lost his patient. He did not believe in irritating the peritoneal surface with dry gauze, as it injured it, and would often prove disastrous to the patient. He used iodoform gauze wrung out of hot sterile saline solution, thus washing the excess of iodoform out of it.

Transverse Incisions in Abdominal Celiotomy.

Dr. Charles Greene Cumston, Boston, for the last eighteen months had been opening the abdomen in many of his gynecological cases by a transverse incision, with a view to securing a more solid cicatrix than he believed could be obtained by a through-and-through incision. The first incision, which he had now made 45 times, is made at the upper limit of the pubic hair transversely, following a line parallel to the upper limits of the pubic hair, making it about a centimeter below the base of the hairy triangle. The skin and cellular tissue are cut through until the fascia is reached; the upper border of the wound is then rapidly dissected off the fascia by a few snips of the scissors and is then held up by a retractor. The lower border of the wound is also dissected off and drawn down by a retractor so that the incision becomes elongated, and if proper traction is made on the retractors by the assistant, a rectangular wound can be made sufficiently large to incise the fascia vertically to the extent of 5 or 6 centimeters. When incising the fascia he thought it better to do so over the inner border of one or the other rectus, and when the belly of the muscle has been freely exposed, its inner border is found and the whole muscular mass pushed aside, thus exposing the thin fascia underneath without wounding the fibers of the muscle in the slightest. After the peritoneum has been opened, the retractors holding the skin flaps back can be removed and ordinary abdominal retractors can then be employed. Through this transverse incision he had performed total hysterectomy with ease, and had done most of the ordinary work on the tubes and ovaries through an incision in the fascia not exceeding 6 centimeters in length. He had enucleated an intraligamentous fibroid the size of a fist through this incision without experiencing any difficulty whatsoever. He also described another incision which he had employed during the past two months nine times with great satisfaction.

Dr. Edwin Ricketts could not agree with the essayist that the incision recommended by him was more advantageous than a median incision, or, in a case of single pus tube, even an opening on one side. In fact, some operators now did not select a median incision, but made an incision either to the right or left.

Dr. J. Henry Carstens saw a general surgeon make a transverse incision in performing a gastro-enterostomy for the removal of the gall-bladder, but he had great difficulty in bringing the muscles and fascia together on account of the tendency to retraction. He thought the incision described by the essayist might prove advantageous for the removal of small tumors where an extensive operation was not needed.

Sarcoma of the Breast.

Dr. Edwin Ricketts, Cincinnati, reported two cases. The first patient was Mrs. McS., aged 64, married, mother of three children. Thirty years before, and at the age of 34 years, she first noticed a hard, round, small lump in her right breast. Eight years after this she called the attention of her family physician to it, exacting a promise from him that he would tell no one. This was twenty-two years before its removal. He advised non-interference. The essayist was called to see the patient in May, 1897; in January before, she had an attack of influenza, and was greatly prostrated from its effects, and from this time the tumor grew rapidly, being nearly the size of a child's head. On his visit he found her with a tumor of the right breast that was about as ugly and vicious looking a growth as he had ever beheld. The cancer was as large as a navel orange, from which a dark sanious fluid was discharging. It was so large that the right arm was forced to project well out from the body. Temperature and pulse were normal. After drying out the cavity it was packed full with 5 per cent. carbolic gauze. The surrounding skin was washed with soap and water, after which pure alcohol was freely applied. No enlarged axillary glands could be felt, especially after the growth was removed. The growth weighed 12 pounds. Although a large woman, he experienced some difficulty in bringing together the edges of the flaps. Axilla was not disturbed. He had two points of suppuration, but barring this her recovery was entirely satisfactory. It was now four and a half years since the operation, and there was no evidence *in loco* or by metastasis. The growth proved to be spindle-celled sarcoma. The essayist then reported his second case.

In the discussion, Dr. Cumston stated that every neoplasm of the breast should be removed as soon as it was palpable. The limit of three years for malignant disease of the breast as a sign that it would not recur was erroneous. He cited a case in point. He called attention to chronic interstitial mastitis, saying that this affection was more frequent in unmarried than in married women. Its pathology was not clear.

Dr. Carstens urged the early removal of any kind of tumor of the mammary gland. He narrated cases in which apparently benign tumors had undergone pathological changes and had developed into sarcomata.

Dr. Humiston held that a great many myomas of the uterus took on sarcomatous degeneration when it was least expected, and detailed an illustrative case.

Dr. Thomas B. Eastman, Indianapolis, discussed two points, saying that surgeons were disposed to search for enlarged axillary glands. Recent investigations had shown that a small gland might be full of carcinoma cells, while the larger glands might be free from them. Both small and large glands should be examined.

Dr. Joseph Price, Philadelphia, stated that for many, many years he had removed the axillary gland in cases of cancer of the breast. He saw Knowsley Thornton, of London, England, do the complete operation for carcinoma of the breast long before it was done at the Johns Hopkins Hospital, and that Thornton stated at that time it was invariably his rule in removing tumors of the breast to clean out the axilla, no matter what the suspicion might be.

Dr. John C. Sexton, Rushville, Indiana, was constrained to believe that sarcoma of the breast was not very rare. He had seen two cases, in one of which there was a rapid recurrence, with metastasis of the ovary of the same side. This was a round-celled sarcoma, which was confirmed by an eminent pathologist. The other case was one of ordinary spindle-celled sarcoma in which recurrence took place promptly.

Dr. Miles F. Porter desired to place himself on record as saying that every tumor of the breast was suspicious, and required operation, and in his judgment any operation which stopped short of complete removal of the breast and cleaning out the axillary gland was not good surgery, and that time would prove it.

Dr. Humiston said the statement made by the last speaker was too radical. Small benign tumors of the breast in young women could be readily removed by cocainization. Sections could be submitted to a microscopist, and if the tumor was found to be malignant a complete operation should be made.

Dr. Cumston believed that chronic interstitial mastitis in the majority of cases was the starting-point of malignant neoplasms of the breast. He urged early radical and complete operation.

Dr. E. Gustav Zinke, Cincinnati, said it was very difficult to say before a tumor was in one's hand or under the microscope what was the actual nature of it. The physician, therefore, was placed in a very embarrassing position. He illustrated this point by narrating an interesting case.

Dr. Baldwin asked whether it was proper to speak of cases in which secondary growths occurred many years afterwards as recurrences. Also, whether it was proper to speak of growths occurring elsewhere in the body as metastases. He mentioned a case in which he removed a sarcoma of the ovary with a long pedicle, but there were no adhesions. A few years afterwards the woman developed a sarcoma of the kidney. He did not consider this a metastasis, nor a recurrence, but a brand-new sarcoma of the kidney. He narrated other cases.

Dr. Carstens made an eloquent plea against the removal of the breast in cases of small benign tumors in young girls of 18 or 20. He vigorously contended that it was bad practice to do it, as it blighted their prospects for matrimony, and it was absolutely unnecessary.

Dr. Ricketts, in reply, endorsed the position taken by Dr. Carstens. In his case, if he had the operation to do over again, he should have removed only the tumor, and not a part of the breast with it.

FIRST DAY—AFTERNOON SESSION.

Galvanism as a Remedy for Uterine Hemorrhage.

Dr. Edwin Walker, Evansville, Ind., stated that galvanism as a remedy in gynecology had been unduly lauded and condemned. Apostoli's method commanded the respect of surgeons, but the results had not been commensurate with claims, and had not been without danger. The minor uses of electricity partook of the character of tinkering, and were objectionable. There still remained a limited field in therapeutics for it, but it did not replace surgery. Its use in uterine hemorrhage was quite satisfactory. It should not be used where the cause of the hemorrhage could be removed by a clean surgical operation. In mild cases, in which the hemorrhage was practically the only symptom, and where no radical operation would be entertained, galvanism was the remedy. In another large class of cases where grave disease in other organs contraindicated operation, relief and often a systematic cure could be effected. Accurate diagnosis of all lesions in each patient was of the highest importance, so that life was not hazarded by an operation in the presence of a serious lesion elsewhere which was overlooked, or the patient, even if she recovered, was not benefited for the same reason.

The method of application was quite simple. The positive pole is attached to a platinum electrode and introduced into the uterus; the negative pole, attached to a copper plate covered with moist absorbent gauze, is placed over the abdomen. The current is gradually turned on until a distinct burning is felt under the negative pole, and continued ten to thirty minutes. Strict asepsis is necessary. The application is not painful. Two to eight applications are required.

Dr. C. C. Frederick, Buffalo, stated that electricity had to a certain extent been replaced largely by surgical procedures. In the experimental stages the results that had been promised by the use of electricity by a great many who were enthusiasts were not borne out. Practitioners met with poor success with it, and in consequence became disgusted and abandoned it, and were now depending upon massage and surgical procedures to control uterine hemorrhages.

Dr. Hayd had used electricity for many years, in fact, for five months he had worked with Apostoli; consequently, he spoke advisedly. When he considered the amount of good that had been done with it in treating pelvic troubles, and compared it with the amount of harm wrought, he felt that it would have been the best thing if practitioners of medicine knew nothing about intrauterine galvanization.

Dr. Price expressed the belief that the application of electricity had a great deal to do in favoring the growth and development of fibroids rather than preventing or arresting them. He detailed two or three such cases.

Dr. Carstens referred to the various causes of uterine hemorrhage. In all cases of excessive hemorrhage there was some cause for it. Sometimes the cause was constitutional and required simply constitutional treatment, but no operation. In other cases the hemorrhage was indicative of malignant disease of the uterus. If the use of electricity was advocated in these cases and the information was circulated among general practitioners that this agent was good for uterine hemorrhage, the result would be that a great many cases of beginning cancer of the uterus would be treated for weeks and months and the golden opportunity to remove the disease by early and timely surgical measures would have passed, and a diagnosis would finally be made too late. He argued against the indiscriminate use of electricity for uterine hemorrhages.

Retrodisplacements in Young Girls and Unmarried Women; Frequency and Best Methods of Treatment.

Dr. Herman E. Hayd, Buffalo, N. Y., drew the following deductions: 1. A plea for the more careful examination of young women by competent and skilled men who can undertake any operative measures that are necessary. 2. Every case of retrodisplaced uterus in the young or unmarried or married woman may not require any treatment. 3. If they produce a definite symptomatology, the Alexander operation should be employed if the case be an operable one, that is, if the uterus is freely movable and the tubes and ovaries are healthy. 4. Retroversions and retroflexions in the young and unmarried should never be treated by pessaries, but by the Alexander operation. Tampons and pessaries have their place in retrodisplacements in married women or women who have been pregnant, but they accomplish practically nothing in the displacements of young women. 5. The Alexander operation is safe and without mortality incident to the operation, and no harm can come from its proper performance; even if the uterus subsequently falls, the patient is no worse off than she was previous to the operation. 6. It does not in any way interfere with pregnancy and future child-bearing, but, on the contrary, materially helps the possibility of pregnancy. 7. No pain or distress follows the operation if the case operated upon be properly selected, and if pain and suffering result, there existed at the time of the operation latent tubal and ovarian trouble, which sooner or later perhaps would have required a radical operation. If it becomes necessary to do a celiotomy on a person who previously had an Alexander operation, the uterus will be found in its normal anteflected position, which is necessary in every case, whether the tubes and ovaries are removed or not, to insure good health and freedom from future suffering.

Method for Suspension of Uterus.

Dr. Robert T. Morris, New York, opens the abdomen in the middle line. An incision two inches long will suffice for most cases. The peritoneum over one round ligament is split and the round ligament is drawn out with a hook for a distance of 3 inches, more or less. Drawing out the round ligament with a hook makes naturally a long loop. The arms of the loop are sutured together with silk or chromic catgut. This throws the sutured part of the round ligament out of commission, and leaves the ligament 3 inches shorter, more or less. The sutured loop is tucked back into the slit in the peritoneum of the broad ligament, and the opening is closed. The operation shortens the round ligaments, and allows the uterus to ride easily and elastically in a normal position. Its advantage over other ligament shortening operations lies in the securing of union of muscular structures. The surgeon does not have to depend upon peritoneal adhesion, which must be a failure in many cases.

Diseases and Injuries of the Cervix Uteri, and Their Treatment.

Dr. J. W. Hyde, Brooklyn, N. Y., presented this paper: 1. In cases where the injury is recent, and the constitution of the patient is so good that no extensive degenerations have occurred—in short, where there is a reasonable probability of being able to restore the cervix to a normal condition, this should be done by Emmet's operation. 2. In old cases, where extensive alterations have taken place, as proved by direct examination, and not less certainly by the unmistakable and intractable reflexes that attend such alterations, the unbearable headaches usually referred to the vertex and the nuchal region, the gastric disturbances, and the endless procession of psychic, neurotic, motor, cardiac, and respiratory aberrations, so familiar to every experienced physician, in such cases trachelorrhaphy is out of the question. To remove all the diseased tissue, and that alone, would call for an unattainable amount of nicety of dissection; and supposing the dissection accomplished, the sewing up of what was left might result in a most interesting thing "of shreds and patches," but it would not be a cervix uteri, which is the only legitimate object of trachelorrhaphy. In such cases, amputation is as effective clinically as it is logical in theory. 3. The operation is not more dangerous than trachelorrhaphy. 4. It is not likely to be followed by stenosis of the canal. 5. There is nothing in the operation that seriously militates against conception, or a normal gestation and delivery.

FIRST DAY—EVENING SESSION.

Mechanical or Combined Plastic and Mechanical Treatment of Retrodeviations of the Womb.

Dr. M. Rosenwasser, Cleveland, Ohio, stated that retrodeviations of the womb were either simple or complicated. The complicated were subdivided into those with movable and fixed womb. Of 116 patients treated for retroversion, 63 of the second and third degrees were selected as proper subjects for mechanical treatment. They were treated by means of the pessary alone, or the plastic operation was supplemented by a pessary. From a table furnishing the details the following summary is obtained: Cured, 11; symptomatically cured, 15; improved, 26; not improved, 11.

In the body of the paper the writer considered each of the divisions, as above classified, and illustrated each by a brief history of typical cases. He maintained that cases of complicated retroversion with movable uterus could be converted into simple ones by plastic operations, and were then subject to treatment by mechanical support. After refuting the objections generally raised against the pessary, he submitted the following conclusions, based upon the present imperfect status of suspension operations: 1. A retroverted womb uncomplicated by disease should be replaced and supported by a pessary. 2. Retroversion complicated by diseased womb, or by impaired pelvic floor, the womb being movable, requires preliminary plastic operation to restore the normal condition before using a mechanical support. 3. Suspension operations should not be done *simultaneously* with the plastic in face of the probability that a pessary can sustain the uterus in position. 4. Retroversion complicated by aggravated prolapsus requires simultaneous plastic and suspension operations to effect a cure. 5. The treatment of retroversion with fixed womb is that for pelvic inflammation. Whenever the latter requires laparotomy, or colpotomy, the retroversion becomes subject to such surgical treatment as may appear best suited to the particular case. 6. Retroversion, simple or complicated, in which mechanical support and plastic operation have failed to cure or to relieve, and in which the symptoms demand relief, constitutes a proper indication for a suspension operation.

SECOND DAY—MORNING SESSION.

Some Observations on the Surgery of the Spleen.

Dr. Lewis S. McMurtry, Louisville, said that knowledge of the physiology and pathology of the spleen is so imperfect that the surgery of this organ has not advanced proportionately with that of the other organs of the abdominal cavity. In view of this fact, every case which may possibly contribute to our knowledge should be studied and recorded. He then reported a case of large cyst of the spleen. The patient was a vigorous woman of 30, well nourished, with a fluctuating abdominal tumor, appearing upon the left side of the abdomen, and readily movable from pelvis to diaphragm. The diagnosis was ovarian cyst with elongated pedicle, or floating cystic kidney. On abdominal section the tumor was found to be a cystic spleen. This was removed without difficulty and without hemorrhage, followed by prompt recovery. A careful microscopic examination showed the cyst to be simple and sterile. Three similar cases were reported. The essayist then considered the technique of splenectomy for cystic tumors of the spleen, commending the median incision and enucleation from below. He stated that it was not the purpose of the paper to consider all varieties of diseases of the spleen, nor to tabulate the statistics of splenectomy for hypertrophy and miscellaneous diseases, but rather to show that cystic degeneration of the spleen is sufficiently common to make a class of tumors deserving recognition as a factor in the diagnosis of cystic tumors of the abdomen. The results of operation in these cases show that the spleen is not essential to life and health.

Is Cesarean Section Justifiable in Placenta Previa?

Dr. E. Gustav Zinke, Cincinnati, went rather exhaustively into the history and literature of this subject and considered the cases reported. He referred to the justifiability of the operation, and the class of cases to which it is applicable. He likewise dwelt on the contraindications to the operation, and compared the management of placenta previa with and without Cesarean section. He believed that the Cesarean and the Porro operations were perfectly legitimate and elective procedures in all cases of placenta previa, central and complete, and especially so when the patient was a primipara, when the os was closed and the cervix unabridged; when hemorrhage was profuse and could not be controlled by tampons and separation of the placenta around the internal os. That there were cases of partial previa that might be successfully treated in the old way, he did not doubt. Perhaps a small majority of all the placenta previa cases could be treated successfully, so far as the mothers were concerned, after the manner of Fry and De Lee. But what of the large minority of mothers that succumb and the great majority of children that are sacrificed at once? The question presented was a very serious one, and should be earnestly considered, and when confronted with a case of central or complete placenta previa, or any other variety, where dilatation of the cervix was impossible or difficult, the patient and her immediate friends should be made acquainted with all the facts concerning both methods of treatment. If properly presented, he thought it was doubtful whether the majority of women would select forcible dilatation, version, extraction, etc.

Importance of the American Medical Association.

Dr. W. E. B. Davis, Birmingham, Ala., delivered the "Presidential Address." After congratulating the *Association* upon the great work it had accomplished, urged the Fellows to use their influence in the better organization of the sections of the American Medical Association. He said: "The greatest and most influential organization in the United States should be the American Medical Association, the brightest lights in the profession should gather at its annual meetings and be prominent in the work of its sections and committees. Failure to be an active contributor to the work of this general national organization should be a deserved reflection on a prominent physician, whether he be a general practitioner or a specialist. It is not enough that our special societies should succeed, but they should prove a source of strength to the entire profession, which can be best subserved by strengthening the American Medical Association, making it not only a power in scientific work, but giving it the prestige which will enable scientific medicine to receive due recognition from our national government."

Surgical Treatment of Biliary Calculi, with Special Reference to Hepatotomy.

The remainder of President Davis' address was confined to the principal operative procedures for cholelithiasis. He favored cholecystostomy, as a rule, for gall-bladder and cystic duct calculi. He said: "Much has been claimed within the past five years for cholecystendysis, with or without drainage of the abdominal cavity. While this operation has something to commend it, being simple and obviating the disagreeable discharge of bile, from three to four weeks, from a fistula, yet its field is limited when the etiology and pathology of cholelithiasis are given due consideration. Stagnation of bile with altered epithelium and infection from the typhoid or colon bacillus as found in many cases, where there is no evidence of infection from the character of the fluid in the bladder, would contraindicate its closure. If stones should be found, where an examination of the gall-bladder is conducted through the abdominal incision made for the relief of pelvic disease or other abdominal trouble, cholecystendysis might be performed with advantage." He advised strongly against the operation as performed by Kelly. The primary incision in the abdomen should be closed and the opening made as in the classical cystotomy. Cases in which calculi would be found by this method are not associated with inflammatory changes, and are the ones who go through life without symptoms referable to the gall-bladder being found at the autopsy or in the dissecting room.

Cholecystectomy.

This operation was reserved for stricture of the cystic duct, inflammatory changes which greatly endanger the walls of the bladder, and malignant disease. In discussing stone in the common duct, he said: "Choledochostomy without suture is called for in the large majority of common duct stones. Suture of the duct may be practiced if the patient's condition has not been rendered serious by much suffering and protracted jaundice, and if the duct is enlarged and not markedly inflamed. Gauze drainage should be resorted to in all cases, it matters not how carefully the stitching of the duct has been carried out. The time required for suturing the duct adds very greatly to the gravity of the operation in cholemia of long duration. It would also be contrary to surgical practice elsewhere to suture when offensive infected bile escapes from the duct. Morison's pouch, which will hold nearly a pint of fluid, makes drainage in this location entirely satisfactory. The lumbar stab is preferred by some surgeons, but the entire safety of transperitoneal drainage has been abundantly demonstrated. Kehr, who has done more gall-stone operations than any other surgeon, claims that he first advised the open treatment of the duct, but it is known that he is in error as the operation has been urged for the reasons he gives, in this country, since the early part of 1892, at which time experiments were conducted by me on the lower animals and reported to the American Medical Association. At that time and for some years afterwards it was admitted by surgeons that the operation would succeed on normal organs with normal bile, but not otherwise. I afterwards induced pathologic changes in the biliary passages and demonstrated that the operation was successful in infected and enlarged ducts. Experimental and clinical experience demonstrate conclusively the safety of the operation."

At the Indianapolis meeting, two years ago, Dr. Davis reported two cases in which hepatotomy had been done in obstruction to the biliary passages. The operation is indicated in cases of obstruction with enlarged liver where the gall-bladder or duct can not be isolated, if the patient's condition from exhaustion and cholemia will not permit of a protracted search for the bladder or ducts. After the patient's condition is better, a rapid operation may be done. It will only exceptionally be called for, and the cases will be fewer as the surgeon's experience increases in choledochus operations; for he will then be enabled to better locate the bladder and ducts so much changed by inflammatory processes. In addition to the above indications, he thought the operation should be resorted to in hepatitis before it has reached the stage of pus formation, if the liver does not rapidly become smaller after drainage of the biliary reservoir of the duct. His attention was first attracted to the value of the procedure in a case in which the amount of pus removed was not more than half an ounce, but in which the division of the biliary canals resulted in the escape of large quantities of bile for many weeks. In December, 1898, he had done hepatotomy on one case in which there was a movable stone in the common duct, and in the same month in a case of obstruction of the hepatic ducts by malignant disease.

In July and August of this year he had conducted a number of experiments on dogs to determine the value of incisions in the liver in relieving biliary obstruction. Five dogs were killed and the liver injected with fluid either through the gall-bladder, the common duct having been tied, or through the common duct. Incisions were then made in all parts of the liver, with the result that streams of the fluid would issue from the bile canals and general oozing of the fluid from the wounded surfaces of the organ if much force was used. Six were anesthetized and the liver injected as above, and this fluid with blood would flow, as a rule, freely when much force was used in injecting the fluid. Four had the common duct tied, and after twenty-four hours the same experiment was conducted under anesthesia, with similar results. In nine the common duct was ligated and gauze packed around the field of the gall-bladder and ducts. After from twenty-four hours to a week the liver would be incised in one or more places, and as a rule the bile escaped satisfactorily through the gauze. It would be very dark after prolonged obstruction. Two of the dogs died and the others were killed in from five days to two weeks. Before killing them and while under the anesthetic, fluid was injected through bladder or duct, and would flow from the wounds which had been previously made in the liver and also from incisions made at that time. Five had the gall-bladder removed and the cystic and common ducts ligated, but as gauze was not used at the time of operation to wall off the general cavity, they died in from twenty-four to forty-eight hours from the escape of bile, with shock.

With the advance in choledochus surgery, the field for cholecystenterostomy grows smaller.

Dr. Davis was assisted in his experimental work by Dr. R. E. Hogan, of Birmingham.

SECOND DAY—AFTERNOON SESSION.

Gallstone in the Common Duct; Its Frequency, Symptoms, Diagnosis and Treatment.

Dr. L. H. Dunning, Indianapolis, Ind., quoted from the recent paper of Mosher, whose compilation of the Johns Hopkins Hospital records shows that gallstones are present in 6.94 per cent. of our population, and that in 13 per cent. of all cases of gallstones the calculus is arrested in the common duct. For convenience of description the author adopted the generally accepted classification of gallstone in the common duct, namely, 1, the acute form in which there is acute obstruction, transient jaundice, and the typical gallstone colic; 2, chronic obstruction of the common duct from lodgment of a stone somewhere in the course of the duct. The first division represents the old classical form of bilious colic and the symptoms are so well known that he did not enumerate them in detail. In chronic obstruction from gallstones the jaundice is more or less intermittent and there is pain in the hypochondrium, epigastrium and back. The pain is not so severe as in acute obstruction, and is very irregular. It may be located in the epigastric or lumbar region. As a rule, there is absence of a tumor in the gall-bladder region, but marked soreness. There is marked loss of weight, and frequently chills and intermittent fever. The Carlsbad cure, a sojourn at the French Lick Springs, large draughts of oil, the application of hot fomentations to the hypochondrium, and opiates to relieve pain are all of benefit in the acute cases. The chronic cases are amenable to surgical treatment alone. The author cited and remarked upon the various methods of surgical procedure. Choledochotomy was shown to be the most approved method when applicable. The middle third of the duct is the point of choice for the incision. When the stone is in the duodenal end of the duct, it can usually be crowded back into the middle portion and removed through an incision in that part. An incision through the cystic duct may be carried onward into and through the common duct if the upper portion be chosen for the line of incision. Duodeno-choledochotomy is applicable to cases of a large fixed stone in the duodenal extremity of the duct. This method yields a higher rate of mortality than simple incision of the choledochus. Only soft stones should be crushed, and needling is unsatisfactory. The writer would reserve cholecystenterostomy in common duct obstruction for those cases in which the patients could not endure the longer operation of choledochotomy. Four cases were reported in detail.

Dr. George S. Peck, Youngstown, Ohio, reported some cases of extrauterine pregnancy, and presented specimens.

Dr. M. Rosenwasser, detailed a case of tubal pregnancy upon which he operated in the eighth week, immediately before the occurrence of rupture.

Acute Pancreatitis and Fat Necrosis.

Dr. Edward J. Ill, Newark, N. J., reported a case because of the rarity of the disease and the interest attached to the operations for this ailment. The patient was a woman, 43 years of age, with the usual history of gallstone colic. She was taken sick suddenly with excruciating pain in the epigastrium, excessive vomiting and obstruction of the bowel. In twelve days after the onset of the disease a tumor was made out. The patient was operated on the twentieth day after the onset of the disease. The diagnosis was perforative inflammation of the gall-bladder, although a pancreatitis and fat necrosis was suggested. The patient's urine contained bile, albumin, and granular casts, with a specific gravity of 1028. It contained no sugar. The operation consisted of a right lateral abdominal section, and an opening between the stomach and the transverse colon through an immensely thickened omentum. Fluid was reached at the head of the pancreas, which was drained through a rubber tube and iodoform gauze. The whole pancreas seemed to be involved in the disease. The omentum upon section showed whitish-gray nodules containing brown roundish spots. For a time the patient seemed to do well, but in about seven weeks she had a relapse from which she died in three weeks. A second operation was done for her relief. At the postmortem it was shown that there were four gallstones in the gall-bladder and only a small mass of substance of the pancreas was left. The author went extensively into the literature of the subject. He mentioned especially the work of Balser, Fitz, Langerhans, Korte, Hildebrand, Robson and others.

Early Operation in Appendicitis and Method.

Dr. Joseph Price, Philadelphia, in the last three months had operated on about one hundred cases of this disease. Seventy-five per cent. had been managed by open treatment. All of them had been explosive cases and none of the operations was done the first or second day. In two ball-players the operations were done on the third day. In both cases he found gangrenous appendicitis with perforations, and general peritonitis. Both were recognized and could have been operated on twenty-four hours early. He was satisfied that there was but one treatment for this disease—early, clean removal of the appendix. The choice of method should not worry operators. A pair of scissors with needles and fine thread was all that was necessary. The appendix should be cut off smooth with the cecum, and the opening closed with fine silk. This summer the operations had been done by him chiefly on children between the ages of 8 and 20. About 75 per cent. were boys—fine, athletic chaps; and about 25 per cent. girls. A large number of the latter were menstruating at the time of the operation. In some instances it complicated the diagnosis. The disease had been quite common and fatal at summer resorts. A large number of operations had been done at Atlantic City, and a few patients were sent home for operations. The interval operation had done much to mislead the general practitioner, and much to complicate operation, in which there should be no complications.

THIRD DAY—MORNING SESSION.

Vaginal Hysterectomy with Four-and-a-Half Months' Pregnancy and Closed Cervix.

Dr. J. Henry Carstens, Detroit, reported a case. The patient was a woman, Mrs. D., only 26 years of age, mother of three children. She was afflicted with some inflammation and ulceration of the womb. Finally a diagnosis of cauliflower growth was made by a practitioner. The cervix was removed in February, 1900. She recovered and improved very much in health; menstruation continued regularly, but during the summer, about six months later, she again had trouble. On examination a recurrent growth was found. This was treated by curetting and strong cauterization, the latter being continuously and vigorously applied. Examination revealed a large uterus such as is found in cases of pregnancy at four and a half months, well marked placental bruit, enlargement of the breasts, etc. The upper end of the vagina was absolutely closed by a cicatrix, as is found after vaginal hysterectomy. There were two nodules, the size of a hazelnut and a bean. By allowing the pregnancy to continue the malignant growth would probably have closed up the vagina and a Cesarean section would be necessary, and the cancer would have so far advanced that there would be little chance for permanent recovery. Hence a prompt operation seemed necessary, but how? If there had been an opening he would have had the physicians insert a catheter and bring on premature labor a week before and then remove the uterus. Having the patient under chloroform he plunged a scissors into the place where he thought the os ought to be. By separating them and stretching the opening with his finger, he tore the sac. By enlarging the opening he had no further trouble in delivering the fetus. By pressing the womb the placenta was soon delivered, although the hemorrhage was profuse for a few minutes, but the uterus contracted firmly, and there was no further trouble. In tearing the opening he fortunately ruptured into the cul de sac. This served as a guide for him to work, and although the uterus was very large, he finished the operation and did a vaginal hysterectomy. Patient recovered and is well to-day.

Indications, Technic, and Remote Results of Salpingostomy and of Resection and Ignipuncture of the Ovaries.

Dr. A. Goldspohn, Chicago, read a paper on this subject, and presented tables of 104 cases. The conclusions of the author are as follows: 1. In patients who are not near the menopause and who are not tainted by tubercular or malignant disease, one or a part of one or both ovaries can frequently be preserved, with or without the retention of the corresponding tube, in the following conditions: (*a*) In follicular cystic degeneration or partially cirrhotic induration due to inflammatory processes or other circulatory disorders; (*b*), in extirpating parovarian cysts, dermoid and fibroid tumors with or without the uterus; (*c*) with great caution, in the extirpation of non-papillary glandular cystomata, that are devoid of surface papillomata and other evidences of malignancy. 2. Necessary for success in the resection of the uterine adnexa is the exercise of asepsis of the highest degree, and the use of a minimum amount of fine and readily absorbable suture material exclusively and judiciously, as to tension. 3. A generous median ventral incision provides the best access for the conservative treatment of the adnexa in cases where septic accumulations in the parts are not absent, and when extreme fixations of the parts abound. When these more extreme complications are not present and a retroversion of the uterus exists, the resection of the adnexa is most easily effected by way of the dilated internal inguinal rings in conjunction with a thorough Alexander operation. 4. Vaginal celiotomy does not provide a favorable access for conservative surgical treatment of ovaries and tubes. It does frequently admit of ignipuncture, but is not auspicious for resection of ovaries. 5. Resection, with the care and technic alluded to, is the m[illegible]al and most conservative measure. and should be pre[illegible] when the parts are sufficiently accessible without undue traction upon their lateral supports, and when asepsis in the surrounding wound and in the general execution is reasonably assured, otherwise thermo-cauterization is probably better.

Dr. C. C. Frederick, of Buffalo, N. Y., read a paper in which he narrated some very rare and old cases and experiences in pelvic and abdominal surgery, and the lessons they taught him.

Dr. Charles Greene Cumston, Boston, reported two cases of hour-glass stomach, and discussed the pathology and treatment.

Personal Experience with Uterine Fibromyomata.

Dr. Henry D. Ingraham, Buffalo, mentioned a large number of cases of uterine fibroids which he had treated by various methods during the past sixteen years. Although he had used ergot freely in many cases, it was only in a very few that it had any effect on the hemorrhage, and possibly hydrastis had in some cases. Stypticin had in his experience appeared to check the excessive flow better than any other drug. He had not obtained any special benefit from the use of the thyroid extract or desiccated mammary gland, and considered their use dangerous on account of their effects upon the general health of patients. He had formerly used electricity with benefit, but did not use it now as the results were not satisfactory. He had had seven cases of quite large fibroids complicated with pregnancy. In five, miscarriage occurred spontaneously. In one it was induced, and in the other the growth almost completely filled the pelvic cavity, the four and one-half months' fetus being above it, so that a hysterectomy was necessary. Patient recovered. One case was mentioned of an unmarried woman who was 64 years of age before the fibroid began to show signs of its existence. For some time it was dense and hard and grew slowly, but for the past few months it had become cystic and increased in size rapidly. This patient manifested several cerebral symptoms on three different occasions, which the author believed were due to some particles of the disintegrating tumor becoming detached, and were carried to the brain, producing these symptoms. On one occasion patient lost sense of motion and sensibility of the right side for over two weeks, and did not know the members of her own family for the same length of time. During the height of this attack the temperature was 101 F., and pulse 96. A year later she had a similar attack, and a few months ago another one, but milder, with no rise of pulse or temperature. He believed that fibromyomata, although considered benign in contradistinction to malignant growths, were by no means harmless, but exposed the patient to great and increasing risk. All cases of fibroids should be carefully watched. If they were not giving any trouble or increasing in size, they should be let alone, but the patient should be kept under observation. When they gave rise to trouble, or if the growth increased in size, then the proper thing to do was to remove it before dangerous complications occurred. If there were adhesions or necrosis of the tumor or pyosalpinx, then the danger of the operation was greatly increased. If cardiac disease or hydronephrosis resulted as a complication, the removal of the tumor would not relieve those conditions. Waiting for the menopause to relieve the diseased condition was often like holding out false hopes to the patient, as the trouble might become worse then than before, or it might all develop after that period, as was shown by the recital of the last case reported by the author. If any treatment was necessary and the patient was in a suitable condition, a radical operation should be done. There was no excuse, in his opinion, whatever for palliative or temporizing treatment at the present day.

Officers.

The following officers were elected for the ensuing year: President, Dr. Edwin Ricketts, Cincinnati, Ohio; vice-presidents, Drs. Charles Greene Cumston, Boston, and Miles F. Porter, Fort Wayne, Ind.; secretary, Dr. William Warren Potter, Buffalo, N. Y.; treasurer, Dr. X. O. Werder, Pittsburg, Pa.

Washington, D. C., was selected as the place for holding the next annual meeting in 1902.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Treatment of the Breasts During Pregnancy and Lactation.

TO PREVENT SORE NIPPLES.

Beginning five or six weeks before the expected time of confinement and continuing its use daily until confinement, lanolin applied externally with friction every night is of great value. The nipple should be thoroughly washed in the morning with pure soap and water, then rinsed off and well dried. The following may be applied locally during the first week or two of nursing:

℞. Tinct. benzoini comp. ....ʒss 2|
Olei olivæ ....ʒii 8|
Lanolini ....ʒvi 24|

M. *Sig.*: To be applied after nursing, three or four times a day.

FISSURES OF THE NIPPLES.

That fissures of the nipples cause very great pain occasionally it is not necessary to state. These fissures are either located at the apex or base of the nipple and cause the mother great suffering when the infant attempts to nurse.

As has been stated by many authorities, cleanliness is the first thing to be observed. The breasts and nipples should be thoroughly washed with some antiseptic such as boric acid solution. This should be done both before and after nursing; the mouth of the infant should also receive proper attention so as to guarantee against any infection from that source. If only one nipple is involved it should be given a rest for a few days and the breast pump used to relieve the breast. An ointment composed of the following will be of great service to hasten the healing process.

℞. Bismuthi subnit. ....ʒiii 12|
Tinct. benzoini *comp. q. s. ad*..........℥i 32|

M. Sig.: To be applied locally night and morning.

Or an ointment composed as follows may be prescribed as used by Hirst:

℞. Iodoformi ....gr. x |66
Ung. zinci oxidi ....℥ss 16|
Ichthyol ....ʒi 4|
Lanolini
Glycerini, āā ....ʒiss 6|
Olei olivæ ....ʒiiss 10|

M. Sig.: Apply locally night and morning.

P. Grossman, Omaha, clinic, recommends the following:

℞. Bismuthi subgal. ....ʒii 8|
Olei ricini ....ʒii 8|

M. *Sig.*: Apply locally night and morning.

He states that it is not necessary to thoroughly cleanse the breast before the child receives the nourishment.

Teisseire, as noted in *Cyc. of Pract. Med.*, recommends orthoform dressings in treatment of fissured nipples. He dusts the powdered drug over the wound and covers it with a compressed layer of the remedy. Over it is placed a layer of absorbent cotton and rubber sheeting, the whole being kept in place by a bandage. Before nursing, the breast should be thoroughly cleansed with warm boric acid solution. The orthoform dressing renders an analgesic effect as well as a curative process.

TO PREVENT FISSURES.

The following application used twice daily will render the nipple and breast firm and less tender:

℞. Glycerol tannici
Aq. destil, āā ....℥i 32|

M. Sig.: Apply locally night and morning.

When the fissures have been formed they may be touched with the following solution:

℞.	Argenti nitratis	gr. x		66
	Aq. destil.	℥i	32	

M. Sig.: Apply locally with an applicator once every other day.

The following is of service as a wash:

℞.	Hydrarg. iodidi	gr. i		06
	Alcoholis	ʒvi	24	
	Glycerin			
	Aq. destil, āā	℥viii	256	

M. Sig.: Use as a wash night and morning.

MASTITIS.

Probably the first thing noticed in beginning mastitis is a hard mass, or what is ordinarily called a "cake breast." This may cause, at first, no subjective symptoms except probably when the infant is at the breast. In a short time the hard mass is painful upon pressure, redness may appear superficially, accompanied by swelling. This is followed by fluctuation. As soon as this is detected active procedures should be commenced at once. And at this point we can not speak too strongly against the applications of poultices in any form. On the other hand, when pus is detected it should be evacuated as early as possible. In making an incision it has been dwelt upon by many to make the incision radiating from the nipple toward the periphery as the spokes of a wheel radiate from the hub. In this way the lacteal ducts are not interfered with and the incision is devoid of any great danger. Drainage and thorough cleansing should be subsequently properly carried out.

Puerperal mastitis tends to recur with each confinement. Traumatic lesions also predispose to puerperal mastitis. Infected cracks or fissures of the nipple are by far the most frequent causes of mastitis. Dr. E. P. Davis recommends that the breast and nipple be washed with castile soap and warm water, the nipple drawn out by the thumb and finger and a suitable antiseptic ointment applied. Stasis of milk in the breast must be prevented. He recommends a solution of boracic acid to preserve the nipples in an aseptic condition. He also states that it is better to err on the side of too early incision than to delay too long. Under no circumstances should the child nurse the affected breast. The same germs which infect the breast may infect the gastro-intestinal tract of the infant.

C. S. Bacon, of Chicago, in an article in *New York Med. Jour.*, states that general precautions consist in washing thoroughly the nipple before nursing and bathing thoroughly with a 75 per cent. solution of alcohol, after nursing, to protect the nipple from abrasions and accidental infections from the mouth or skin of the child. He chooses alcohol as a disinfectant, because it is harmless to the child, and at the same time efficient. He also recommends the nipple shield as of great importance in the prevention as well as the cure of nipple wounds. If the nipple wounds do become infected, but no symptoms of general infection or involvement of the deeper breast, the local wound should be treated like wounds in any other part of the body. The application of cotton saturated with alcohol is usually sufficient, but the appearance of chills and fever indicates deeper infection of the breast. When these symptoms appear Dr. Bacon restricts nursing from the affected breast and supports the breast with a proper bandage. With this treatment he states that from 80 to 90 per cent. of the cases will terminate without abscess formation, and if an abscess does form it will be localized to one lobe as a rule. If pus formation is suspected he recommends that the hypodermic needle be used to determine its presence; and if the abscess is present, however small, it should be opened at once. If in doubt, continue the support and ice-bag to the breast. This will limit its formation and the pain. He denounces the treatment by poultices, which allows a considerable portion of the breast to become involved and broken down. He recommends that a few drops of Schleich's solution be injected beneath the skin, making the line of incision anesthetic. The pus should be washed out with sterilized water and small amount of sterilized gauze introduced for drainage. This may be ved in twenty-four hours and the wound kept open for one o days by irrigation, when it will usually close itself.

Dr. Rubeska, in *Centralblatt f. Gynekologie*, states that in 3152 nursing women he has observed 1244 cases of sore nipples. He recommends, as treatment, the use of compresses moistened with a 3 per cent. solution of boric acid and covered with gutta percha. He states that lactation was continued in almost all the cases, the nipple being simply protected with a shield. In three-fourths of the cases the trouble subsided within ten days, and mastitis developed in less than 2 per cent. of the cases. He further states that when mastitis did develop the breast was thoroughly disinfected, and compresses damp with a solution of bichlorid of mercury, one-half per cent. strength, were constantly applied for three hours; the first milk was drawn artificially with the pump and the ice-bag afterwards applied. If the signs of inflammation first developed with a chill followed by a high temperature accompanied with pain he immediately ordered an injection of a 3 per cent. solution of carbolic acid into the affected breast, as much as two or three Pravaz syringefuls being injected at one time. If the trouble began less severely this was not carried out unless the pain and temperature continued longer than forty-eight hours. He states that suppuration took place in only two cases following this treatment, and no harm was done in any case.

Hirst states that if the abscess is opened early one incision commonly suffices. If the case is neglected every pocket of pus must be opened and every sinus drained to secure a permanent cure. The incision should radiate from the nipple and the area of pigmentation should be avoided as far as possible or the incision should be confined wholly within this area as the pigmentation will follow the cut, disfiguring the breast. The abscess cavities should be compressed, after being opened, by a firm binder and the wound irrigated daily with sterile water.

In threatened mastitis the following ointment may be of benefit in some cases:

℞.	Ichthyol	ʒiv	16
	Ung. hydrarg.	ʒiv	16
	Ung. belladonnæ	℥ss	16
	Cerato plumbi subacetat.	℥i	32

M. Sig.: Apply locally three times daily.

Proper attention to elimination in such conditions as the foregoing should not be neglected. Elimination should be promoted by the bowels and kidneys. Salines should be administered until free action of the bowels is produced. The following may be used under the same conditions as the above:

℞.	Zinci oxidi		
	Ung. belladonnæ āā	℥ss	16
	Ichthyoli	ʒii	8

M. Sig: Apply locally twice or three times daily.

GALACTORRHEA.

The following is sometimes applied locally in connection with supporting treatment of the breast:

℞.	Ung. belladonnæ		
	Lanolini āā	ʒiv	16

M. Sig.: Apply locally twice daily.

Medicolegal.

Non-Expert Witnesses in Inquiries as to Sanity.—The Supreme Court of Alabama holds, in the murder case of Caddell vs. State, that on an inquiry of sanity or not, the rule applicable to non-expert witnesses is that opinions opposed to sanity are admissible only when stated in connection with the facts respecting the conduct, abnormal or otherwise, of the person whose sanity is questioned; but opinions affirming sanity may be based on a mere negation of unnatural or peculiar conduct, without a specification of facts.

No Damages Recoverable for Injuries to Unborn Child.—The Supreme Court of Rhode Island holds, in the case of

Gorman vs. Budlong, that one can not maintain an action for injuries received by him while in his mother's womb; and that, consequently, his next of kin can not maintain an action, after his death, therefor, under the statute of that state, which provides that whenever the death of a person shall be caused by the wrongful act, neglect, or default of another an action may be maintained for damages if he could have maintained one had death not ensued.

The Testimony of Paid Medical Experts.—The Supreme Court of Tennessee holds, in the case of Bateman vs. Ryder, that there was no error in the trial judge charging the jury that "the testimony of experts introduced for the purpose of establishing insanity or mental unsoundness, if paid for, should be received with great caution and carefully weighed by the jury," the judge charging further, upon this feature of the case, that "it was lawful and proper for an expert physician to charge a reasonable compensation or fee for his professional opinion or services."

Not Required to Refund Cost of Medical Treatment.—Without passing upon the question of whether or not it is necessary, as a condition precedent to the commencement of an action in a personal injury case where a release has been signed, that the money paid therefor should be refunded, it being alleged that the party was in such a condition when he signed it as not to understand what he was doing, the Supreme Court of Colorado holds, in Town of Colorado City vs. Liafe, that, no money having been received, the only consideration for the release being the furnishing of surgical and medical treatment and care at a hospital, it is not necessary for the injured party to ascertain the amount paid to third parties therefor in his behalf and to refund same before commencing his action. It thinks it enough, as well as proper, that the jury be instructed that if he is given a verdict the amount shown to have been paid for his benefit under the terms of the release should be charged against him.

Mental Injury from Wilful Wrong.—The first appellate division of the Supreme Court of New York holds, in the case of Williams vs. Underhill, that the rule that damages resulting from fright alone, or for mental suffering disconnected from other injuries, can not be recovered, applies only to actions based on negligence, and not to cases of wilful tort or wrongful acts. The reason for limiting liability in actions for negligence, it says, is founded in the principle of law governing such actions, namely, that the measure of damage shall be confined to the natural and probable consequences of the act or omission constituting the cause of action, while the distinction between such a case and one founded upon a wilful tort, such as an assault, is very clear. So, evidence having been admitted in this case, without objection, which tended to prove the commission of an assault, and that prior to the same the party suing for damages therefor had been a person of unusual mental strength, the court holds that it was error to exclude testimony offered to show the effect of the assault upon her mental condition, and of the medical treatment received by her therefor, even if she had limited her claim to damages for mental injuries resulting from fright alone.

Authority Required for Compulsory Vaccination.—As a question never before raised in that state, the Supreme Court of Michigan takes up, in the case of Mathews vs. Board of Education, that of the validity of compulsory vaccination of school children. It appears that in 1894 this Kalamazoo school-district board enacted the following rule: "No pupil shall be admitted into any public school who can not furnish satisfactory evidence that he or she has been vaccinated or otherwise secured against smallpox, and no pupil affected with any contagious disease, or coming from a house where such a disease exists, shall be allowed to remain in any public school." This rule continuing in force, a Christian Scientist brought this suit, denying its validity. The court, however, does not feel called upon to discuss the question of his religious scruples. It points out that, inasmuch as the law of the state makes it the duty of the child to attend school, and of the parent to send him, under penalty of fine or imprisonment, or both, the effect of the rule referred to would be to compel the vaccination of the child, or subject him and the parents to the penalties of the law, the practical result of which would be to give the board of education the right to compel compulsory vaccination, if the rule could be sustained. Wherefore, the legislature not having undertaken to give the board the power, when no epidemic of contagious disease exists or is imminent in the district, to pass a general, continuing rule which would have the effect of a general law excluding all pupils who will not submit to vaccination, the court, divided three to two on the proposition, holds that the school board exceeded its power. At the same time, it does not mean to intimate that during the prevalence of diphtheria or smallpox, or any other epidemic of contagious disease, in a school district, the board may not, under its general powers, temporarily close the schools, or temporarily say who shall be excluded from the schools until the epidemic has passed. Again, it says that in the absence of any statute authorizing compulsory vaccination, or which requires vaccination as one of the conditions of the right or privilege of attending the public schools, it thinks it can not be maintained that the rule relied upon was a valid exercise of the rightful powers of the State Board of Health. Its powers, though quite general in terms, must be held to be limited to the enforcement of some statute relating to some particular condition or emergency in respect to the public health; and, although they are to be fairly and liberally construed, yet the statute does not, either expressly or by fair implication, authorize the board to enact a rule or regulation which would have the force of a law changing the statute in relation to the admission, and right of pupils of a proper school age to attend the public schools. It is not a question, the court continues, as to what the legislature might do, under the police power, about requiring vaccination as a prerequisite to attending school; nor is it a question of whether the legislature could confer this power upon the school board. To lawfully exclude children from the public schools for the cause relied on requires such a change in the existing law as the legislature alone can make.

AMERICAN.

2. **Tuberculous Laryngitis.**—Thomson recapitulates the principles to be borne in mind in tuberculosis of the larynx, as follows: Pathology and clinical experience show that in the majority of cases the focus of infection is near or in the crico-arytenoid joint. Many cases present themselves only at the stage when local treatment is incapable of producing cure and we should keep the principle of doing no harm constantly before us in this affection. The most rational principle, according to our present knowledge, is to make an early diagnosis in its incipiency. Any suspicious laryngeal catarrh should be treated seriously on even a presumptive diagnosis. Once diagnosed, the patient should be treated on the principles laid down in modern sanatoria. Symptomatic treatment should be directed to any irritative, catarrhal or obstructive condition of the air passages. Silence should also be enjoined, the disuse of the voice being in proportion to the degree in which the focus of infiltration approaches or interferes with the arytenoid joint. Where the situation or extent of disease does not warrant an expectation of complete arrest of the process, treatment should be symptomatic, and sanatorium methods are unnecessary.

3. **Urea in Tuberculosis.**—After mentioning the general dissemination of tubercle bacilli and the universal exposure to it, Buch remarks that most of us must have some vito- From the observation that the kidneys are practically immune to any ordinary infection, and it must be a substance or element that is not harmful or foreign to the human organism. From the observation that the kidneys are practically immune to phthisis, Harper of Nottingham concluded to prescribe pure urea with a view of increasing the amount of urea and uric acid, and Buch follows this suggestion in his present paper, holding that urea is probably a substance which has something to do with this immunity. While it is impossible to understand precisely why and how it causes beneficial effects, he thinks there is sufficient clinical evidence already to show that it is beneficial, and he reports seven cases of tubercle infection that were treated with good results: either cured or with more or less disappearance of symptoms. In all the other cases in which he has used the treatment he had had similar good results.

8. **Functions of the Tonsils.**—Matheny pleads for the preservation of the tonsils, holding that these are really protective organs, ranged around the pharynx to protect the system against infections which may enter by that route. He does not admit that simply because a tonsil projects into the pharynx beyond the level of the faucial pillars, it is hypertrophied, or even if it is hypertrophied that it is dangerously pathologic. The question is whether it has lost its function and is inimical to life, and he lays down the conditions under which excision is justified, including mechanical obstruction produced either of the pharynx or Eustachian tube, and specially liability to recurring attacks of tonsillitis, where the function of the organs has been destroyed and degeneration has taken place, a condition in which the crypts have become filled with caseous matter, cases where lacunar ulcerations are present, when a quinsy habit has been acquired, cases of malignant disease of lupus or tuberculosis of the tonsils and where enlarged tonsils interfere with voice production. Also in some cases after the age of puberty there sometimes remains more or less fibrous tissue, occupying the tonsillar space which has lost its lymphoid characteristics, and partakes of the nature of a foreign growth inimical to comfort. The differential diagnoses of several of the different disorders given, such as acute follicular tonsillitis, herpetic tonsillitis, and ulcerative lacunar tonsillitis.

13. **Alcohol.**—Didama's article argues against the use of alcohol even in moderate doses, not only as a beverage, but also in medical treatment. He finds from his own personal experience that the non-alcoholic treatment of any disease is far more satisfactory than the alcoholic management formerly employed.

14. **Atropia in Pulmonary Edema.**—O'Donovan finds that atropia is a remedy that rapidly contracts the vessels, powerfully stimulates the sympathetic system, increases the force of the heart's beat, raises arterial tension, stimulates the respiratory centers, and dries up the secretions of the skin and mucous membrane. Its physiologic action can be easily gauged by watching the amount of dilatation of the pupil. It is well to supplement it with some drug that acts promptly and surely as a direct stimulant to the heart, strychnia preferably. In cases of acute pulmonary edema he has seen relief from the hypodermic injection of 1/100 of a grain of atropia with 1/50 of a grain of strychnin sulphate so immediate and complete that it seemed like magic. The pulse should be watched to see that the effect is not merely transitory. Time should not be wasted on remedies given through the stomach, but the hypodermic should be used at once.

19.—See also title 17.

20. **Malignancy.**—Blake gives an abstract of the recent work by Professor Schüller of Berlin, entitled "Die Parasiten in Krebs und Sarkom," in which he holds that he has found a parasite which can be grown in pure culture, readily identified, occurs invariably in tumors and is reproduced by inoculation. It certainly can not be identified with blastomycetes, but apparently belongs to a class of animal parasites of which practically nothing is known. Certain researches of the author tend to show that the non-malignant tumors are produced by somewhat similar parasites belonging to the same class, but under certain conditions they are transformed into the malignant form, or assume malignant qualities which result in the same proliferation of cells. The researches of Schüller tend to prove the infectious nature of the disease, but how it is propagated is absolutely unknown. Analogy would suggest that some form of the organism must exist outside of the body and many histories tend to confirm this view, but it remains for future study to settle this point. The parasite seems very sensitive to cold and ordinary antiseptics, therefore, the danger of infection during an operation must be slight, though the continued association with an infected person is more open to question.

25. **Eosinophilia.**—Williams calls attention to the association between eosinophile leucocytes and the spermine crystals first noted by Charcot and Leyden, and suggests that this may have a pathologic importance as indicating the decomposition of nuclein in the body. As to what cells are being decomposed it is not always easy to say.

29. **Cystitis.**—The treatment of cystitis depends upon the forms of inflammation, and Chassaignac, before taking these up seriatim, mentions certain general methods, such as rest, which is the more important the more acute the case; diet, which should be non-irritative, alcohol being excluded, the use of laxatives and baths; hot applications over the bladder, and intravesical irrigations and alkalines to diminish the normal acidity of the urine; anodynes and urinary antiseptics are also useful in the majority of cases, and the above measures are applicable in all stages and in all forms of cystitis. In gonorrheal cystitis, specific remedies such as salol, sandalwood oil, local treatment with potassium permanganate, etc., are advised. In the tuberculous form the prognosis is not good. He thinks that if ulceration is present, the patient's general condition being fair, a suprapubic cystotomy which will facilitate curettage and topical applications is advisable. The cystitis of stricture, prostatitis, calculus and tumor should be treated in addition to the general measures by the treatment of the local lesion. In traumatic cystitis the special indication is to keep the organ well drained in order to avoid complications due to leakage. Cystitis from direct infection is usually due to lack of care in the treatment and the precautions should be prophylactic. When the inflammation travels downward from the kidneys or ureter, only temporary results will follow local treatment of the bladder. Healing of the ureter or kidney and removal of these organs if necessary, are the only means of producing a cure. In cases of cystitis from irritants taken internally, their stoppage usually ends the disease.

31. **Rheumatism in Children.**—Several patients suffering from rheumatism in the same family are noticed by Mitchell who thinks that these indicate the infectious character of the disease. Three of the cases were children. He points out the special characters of the disorder in young patients and emphasizes the importance of protection of the heart and of guarding patients from relapses and recurrences after the first attack.

38. **Malaria.**—The treatment suggested for malaria by Shropshire is, first, "Stop every case of malaria at once by adequate doses of quinin, for the longer it runs the greater the number of gametocytes formed in the blood, and the greater danger is the patient as an infector. By adequate doses I mean not less than two grams of quinin, and that either in an acid medium, or followed by an acid that will make the medium acid after it is taken; for quinin will not absorb in an alkaline medium. When the paroxysms are broken the patient should be required to take one gram at bedtime and half a gram the next morning on every sixth day for two months or more, and to sleep under mosquito netting or in well-screened houses the remainder of the warm season in our country. Urge the drainage of all places calculated to afford larval development of the mosquito, and if drainage is impractical, treat them once a week with petroleum, even Beaumont oil would do." In addition, he says educate your patients up to these requirements and teach them that curing each case promptly lessens the danger to other members of the family and community.

40. **Ventral Fixation.**—The operation here claimed as original by Michaux is as follows: The abdomen was opened in the median line, the uterus taken out and carried somewhat back, the cervix was then dilated by an assistant, the organ was then put in the usual position for ventral fixation and stitched with two sutures to the lower end of the abdominal wound, but a little higher up than is done when the operation is undertaken for the relief of posterior displacements, with a view of straightening out the bend in the canal.

41. **Hyperthropic Rhinitis.**—The special points deduced from Robertson's consideration of the newer methods of treating this condition are: The uselessness of sprays, galvanocauteries, etc. 2. Where growths exist they should be treated as growths which appear elsewhere. 3. The saving of all the

mucous sinus tissue possible, still securing breathing space. 4. The advantages of the use of suprarenal capsule. 5. The absence of danger of synechiæ, due to cautery, etc. 6. The use of dry pledgets of cotton and the disuse of all others. 7. The great advantage of the greased gauze as a surgical dressing in the nose over old methods. 8. The danger in the use of cocain lessened by the use of suprarenal extract. 9. The disappearance of nasopharyngitis after the nose becomes ventilated.

44.—See abstract in THE JOURNAL, xxxvi, p. 1726.

45.—Ibid.

46.—Ibid., p. 1727.

47.—Ibid., p. 1726.

48. **Filarial Lymphatic Varix.**—There seems to be little doubt that this disease prevails to a limited extent in the Southern States, and may be acquired in this country. It has also been observed even as far north as Pennsylvania. Opie reports a case at length with postmortem findings. He calls attention to the fact that the lymphatic vessels throughout the varix were filled with blood and not with lymph, suggesting regurgitation at some point of connection between the venous and lymph systems.

49. **Glandular Degeneration of the Erythrocyte.**—The conclusions arrived at by White and Pepper are: "1. The granules are a constant finding in cases of lead-poisoning, and appear very early in cases under the influence of lead salts long before subjective or other objective symptoms can be demonstrated. 2. The granules disappear in cases of chronic lead-poisoning as the convalescence is established. 3. Apparently lead does not produce an immunity, as one of the cases worked for twenty-four years, another for twenty years, without having pronounced symptoms of lead-poisoning, and in both of these cases the granules were present in moderate numbers. 4. The granules may be produced experimentally in dogs, appearing in a very few days after the beginning of the experiment, and increasing as the intoxication becomes severe. 5. The granules in the experimental cases are rather fine, and show a tendency to clump at first; later, all varieties appear. 6. We believe these granules to be a true degeneration of the erythrocyte and having no relation to nuclear fragmentation or to polychromatophilia."

51. **Hydatid Disease of the Breast.**—Leconte reports a case occurring in a mulatto girl, aged 27, which was apparently the first of its kind in this country. He tabulates the published cases and finds that the disease is confined to women usually in early maturity or from the age of puberty to the climacteric. It is characterized by the appearance of a small, hard, painless tumor situated in any part of the surrounding tissue of the breast, freely movable and slow in growth. The firmness continues until it attains considerable size and even then its cystic nature is not apparent. The enlargement of the axillary glands, pain, irregular outline, and adhesions to the skin are characteristic of inflammation outside the sac and degenerative change leading ultimately to the death of the organism and spontaneous cure. The diagnosis is difficult and malignant growth often seems probable. The treatment should be always operative.

52. **Sporadic Cretinism.**—After reporting a case Packard and Hand call attention to certain points which seem to them of interest, namely, the rapid improvement under the use of specific drugs, thyroid extract, though the patient finally succumbed to acute disease, the system seeming unresistant. Besides the thyroid changes there was also an abnormally large hypophysis, a condition which has not been very frequent in such cases. Another point of special interest is the calcareous infiltration of the blood vessels of the thyroid which seems not to have been mentioned in the literature of similar cases.

53. **Pneumococcal Mucous Inflammation.**—The points of interest in the case reported by Carey and Lyon are the occurrence during the course of an attack of lobar pneumonia in a boy of 11 years, of a profuse pseudomembranous exudation of nearly all the mucous surfaces of the body open to inspection, caused by the pneumococcus. The case also showed signs of excessive adhesive pleuritis and marked and continued tympanites with discharge of membranous shreds in the stools, suggesting that the fibrinous process involved also the pleura and gastro-intestinal tract. In other respects the case was not remarkable, terminating by gradual lysis with recovery.

54. **Splenic Miliary Tuberculosis.**—Stewart reports the second case on record of splenic miliary tuberculosis apparently due to contagion. The patient had nursed a consumptive while suffering from the after-effects of la grippe, with reduction of bodily resistance. The patient's room was damp and cold. The nurse was constantly in attendance, lost much sleep and was poorly fed.

56. **Blood Changes from Ether.**—The assertion made many years ago that anesthesia has a destructive influence upon the blood has been the cause of experiments by various investigators and Da Costa and Kalteyer report the results of their own examinations in 50 cases, also of experiments on animals. The conclusions to which they arrive are given in substance as follows: 1. The number of red corpuscles is influenced by many factors associated with and accompanying the anesthetic state. The character of the change is, as a rule, polycythemia, rarely, an oligocythemia. These factors may be grouped into three classes. In each class when analyzed separately is found cause capable of producing an increase in the number of colored corpuscles. 2. The nature of this polycythemia seems best explained by a lessening of the watery element of the plasma, thereby reducing the total volume of liquor sanguinis, and causing concentration of the blood. They think it reasonable to infer that the polycythemia is not specially influenced by excessive proliferative changes which probably occur in the hematopoietic tissues. The increased blood production is an effort of Nature to rapidly restore the destroyed cells. 3. The three important factors incident to the polycythemia are (a) The period of preparatory operative treatment; (b) the anesthetic state; (c) the post-operative stage. 4. The blood inspissation is, as a rule, most pronounced immediately after the termination of the anesthetic stage. In some cases the anhydremia may be increased by each succeeding factor, or one of these factors may exceed the other. The variation existing between the plasma and corpuscles, though temporary, should be regarded as too pronounced to be within the physiologic limits. The relative increase in the number of erythrocytes is generally still present sometime after the operation, but not infrequently the readjustment occurs before this, and an oligocythemia may be present. 5. The hemoglobin is always reduced absolutely; in some instances there is an apparent increase, but this is never parallel with the rise in the number of red-blood cells. The individual corpuscular hemoglobin value is therefore reduced. This reduction in the color value of the chromocytes is most striking when compared with the blood decimal, determined sometime after the operation. We must conclude that etherization produces increased hemolysis, and in Nature's effort to rapidly replace the destroyed corpuscles, the regenerated cells are imperfectly supplied with hemoglobin. 6. The duration of the anesthetic state and the amount of ether may influence the blood changes; but the extent of the disturbances could not be determined on account of the many modifying factors. 7. The amount of blood loss, as encountered in this series of cases, does not seem to affect the blood. 8. Whenever possible, one or more blood examinations should be made before giving the general anesthetic, and these before preparatory treatment has been instituted. On account of the hemolysis which is shown by the fall in the corpuscular hemoglobin after operation, a very low percentage of hemoglobin must be regarded as a contra-indication to general anesthesia. The amount which should be regarded as a positive contra-indication is uncertain, and the authors think that below 50 per cent. is a dangerous level. In malignant disease and in cases where surgery might prolong life briefly, but can not cure, operation should not be performed under general anesthesia when the hemoglobin is below 50 per cent. They operated in two cases where it was below 40 per cent.,

but in each case a vital emergency existed, and in each case death on the table was narrowly averted. Mikulicz gives 30 per cent. as the lowest level at which operation should be attempted, but the authors give 40, excepting under stress or absolute necessity. In case of low percentage of hemoglobin local anesthesia should be employed whenever possible and in any case where the percentage is low, the ordinary preparatory measures should be employed in every way to avoid creating undue drain upon the blood. The anesthesia should be entrusted to an experienced hand and as little anesthetic used as possible. The operation should be performed rapidly, the proper measures taken to bring about reaction after it is completed, and oxygen should be inhaled to remove the ether quickly from the lungs and blood.

57.—See abstract in THE JOURNAL, xxxvi, p. 1490.

58. **Sarcoma.**—Wyeth calls attention to the malignancy of sarcomas and suggests that in his own practice he can recall but two cases that could in the strictest sense be called cured. He has collected the statistics of a considerable number of cases, including those reported by Chavasse, and finds comparatively few in which recurrence did not take place. The two cases mentioned by him as cured are reported at length.

61. **Fracture of the Skull.**—In concluding, Lathrop says that fracture, whether compound, depressed, or comminuted, should be treated by operation. In all simple fractures where the slightest indication of intracranial pressure or hemorrhage is present, operate. Even simple fractures followed by no symptoms need watching, and especial care to the general system. The prognosis in fractured skull is to be guarded, and to be guided by subsequent development. An abnormally low temperature followed by rapid rise is a bad sign, and coma, paralysis, deep, irregular breathing, and dilatation of the pupil are nearly always of fatal significance. A temperature at or above normal rising one or two degrees with regular respiration and full or slightly accelerated pulse is usually favorable.

62. **Pott's Disease.**—The object of Whitman's paper is to advance the proposition that horizontal fixation should be the routine treatment during the destructive stage of Pott's disease in early childhood, a doctrine which is not generally taught nor accepted.

65. **Aortic Aneurysm.**—After reporting a case in which, nine weeks after the operation, the man was well enough to leave the hospital with good consolidation of the anterior portion of the aneurysmal sac after the introduction of wire by the Corradi-Stewart method, Willard discusses the subject and analyzes the reported cases. He thinks while the operation produces few permanent cures, it at least lengthens life, and in all of those who survive the immediate effects relieves the individual symptoms. Considering that these cases are fatal if left alone, these results are certainly satisfactory. To conclude, he says that, in his opinion, it offers a more reasonable hope of success in bad cases of thoracic aortic aneurysm than any other method yet devised.

67.—See editorial in THE JOURNAL of September 21, p. 777.

69. **Tuberculous Disease of the Spine and Hip.**—Phelps describes the condition in detail and points out the approved methods of treatment, illustrating the orthopedic apparatus. The importance of symptoms is given by him in the following order: 1. Limit of motion. 2. Deformity with apparent or real shortening. 3. Limp. 4. Atrophy and bone disease. 5. Pain in the knee with absence of local disease. 6. Pain on joint pressure. 7. Night cries. 8. Flattening of buttock. 9. Heat. 10. Swelling. He opposes the use of the long traction splint and favors the use of the plaster-of-Paris without passive motion. We have outgrown the idea that fixation will produce anchylosis, but he also gives descriptions and illustrations of perineal crutches used by himself, which meet the indications of fixation and traction in the line of the neck without absolutely confining the patient. We should operate in case of tuberculous abscess whenever the capsule is ruptured, in rapid osteomyelitis, in all tense abscesses and wherever necrosed and carious bone is present; also in rapidly increasing abscess of the joint filled with tuberculous purulent material, when the abscesses are repeated in occurrence and in any case with rise of temperature; also whenever there is doubt as regards the diagnosis.

70. **Local Anesthesia.**—Floeckinger credits Corning with the first discovery of the method of local anesthesia, it having been subsequently developed by Oberst, Schleich, Braun and others, and describes his method of applying it in various conditions.

71. **Cough.**—The conclusions of Levien's article are that: "1. Cough, though one of many features in the make-up of tuberculous affections of the lungs and larynx should, however, receive special attention at the hands of the physician, because it is the most distressing and exhausting factor. 2. Of all the remedies and drugs in our experience, which would tend to ameliorate and suppress cough, we find in glyco-heroin an agent which to all appearances is a remedy par excellence, and we recommend its further trial."

72. **Asthenopia.**—According to Howe, asthenopia is more frequent in this country than abroad, which he attributes to the prevalent carelessness in the use of the eyes, overstrain in business, indigestion, etc. He also finds that a larger number of persons are relieved in this country; the American seeks relief in glasses earlier than do foreigners. The average American practitioner is better fitted to detect and meet the conditions and American ophthalmologists and opticians are better supplied with diagnostic appliances and stock for such cases.

79. **Ear Disease.**—The neglect of aural affections by the general practitioner is deplored by Barnhill, who pleads for a better natural understanding between him and the aural specialist. The common indifference of the public to these disorders, careless statements by physicians to patients, and the comparative lack of aggressiveness of otologists in presenting the importance of their work are, he thinks, responsible for the present state of things. Careless dismissal of a case with an ear-drops prescription and promise that a child will outgrow it, are causes of much later trouble. Morris' remark that if the graves of those who died of neglected appendicitis were marked with lights, graveyards would be well lighted, is applied by Barnhill to ear disease. He insists on the importance of attention to the patency of the Eustachian tube, and of early incision of the drum when needed in cases of acute aural disease. In chronic otorrhea the family physician is justified in attempting to treat it for a time, but after a few weeks' ineffectual trial he should call in the aurist.

81. **Ether Anesthesia.**—Eastman advises warning the patient that he will experience unusual sensations, choking, etc., but he must pay no attention to them. The best inhaler is that with the largest evaporating surface. Ether should never be used except from a freshly opened can, the room must be quiet, and the anesthetizing is best done in the patient's room. The more rapidly anesthesia is produced the better. A competent anesthetizer can do it safely in eight minutes. Lower the inhaler gradually on to the face, thus avoiding shock to the mucous membrane. Do not test reflexes by jabbing finger into the eye; the respiration will, if watched, give sufficient information. After a short time the respiration will apparently stop, but if the pulse continues good, this ought not to alarm. The administration may be continued quietly and all will be well.

84.—This article appeared in THE JOURNAL of July 6, p. 1

95. **Hemolymph Glands.**—The anatomy and histology of these glands is described by Warthin, who recognizes two types which he classes as the splenolymph glands and the marrowlymph glands, though all sorts of transition forms are found between the two. He notices the pathologic conditions which may affect these, such as pyemia, anemia in the various forms, etc. Under normal conditions they are most probably concerned in hemolysis and leucocyte formation and play but little part, if any, in formation of red blood cells. Study of these glands he thinks points to a new and important line of

investigation as regards the solution of problems relative to blood formation, and pathologic conditions of the blood and blood-forming organs.

96. **Tumor Transplantation.**—Loeb details experiments which he has performed in an attempt to transplant cystic sarcoma from the thyroid of a white rat into some 150 other animals and describes at length the changes observed. All the successful cases were in rats; the experiments on guinea-pigs failed. The probability is that in every case tumor cells were transplanted and started a new growth. The possibility, however, of transplantation of micro-organisms as the cause of tumor growth can not, he thinks, be overlooked.

99. **Pest Bacillus.**—From experiments in the Hoagland Laboratory, Wilson concludes that probably the most important points in suspected cases of pest bacillus are the stalactite test, its behavior on salt agar, and the vaccination of rats and guinea-pigs with suspected material. Though there is no positive characteristic by which the bacilli of the pest can be hurriedly identified, one can, by these means, be reasonably certain of its identity.

101. **Trichinosis.**—According to Williams' investigations, it seems probable that many cases of old trichinosis escape detection at autopsies. In 27 cases out of 505 unselected autopsies in the adult human subject, trichinosis was present, all having died of other disease than trichinosis. In some of the cases the infection was extensive, in others very slight. The birth-places of the subjects included almost all the important countries of North America and Europe. A very large percentage of the cases occurred in subjects that had been insane.

104. **Gas Cysts.**—Howard believes that there should be more frequent and careful examination of the brain at autopsies; especially in cases of general gaseous emphysema it would probably show that gas cysts are more common than generally supposed.

105. **Proteolytic Enzymes on Bacterial Toxins.**—Baldwin and Levene have experimented on cases of proteolytic enzymes and neutralizing bacterial toxins, it being well known that many bacterial toxins ingested by the mouth lose their toxicity. They find that the diphtheria and tetanus toxins are both digested and not simply neutralized by the three proteolytic enzymes. In regard to tuberculin it may be stated in a general way that trypsin and pepsin digestion weaken its specific activity. Trypsin on prolonged digestion is able to destroy all the activity of tuberculin, while this could not be achieved by pepsin. He therefore thinks that tuberculin is a specific substance of the nature of a nucleo-proteid, the latter being the reason for its being more easily destroyed by trypsin than by pepsin.

110. **Bacteriolysis and Typhoid Immunity.**—While he does not claim his studies are complete, Richardson thinks the following conclusions may be made or suggested: "1. *In* typhoid fever Nature produces a cure through bactericidal agents acting upon the specific bacilli. These agents are produced by body cells, especially those of the lymphatic apparatus, and are found in varying amounts in the blood. 2. These protective agents are at least two in number, a specific immune element and a non-specific normal element or ferment. 3. It is the function of the immune element to bind the complement or ferment to the bacterial cell, which is then destroyed. 4. In the earlier and middle stages of the disease the immune body may apparently be present in large amount, and yet be of little value because of the absence of the complement. 5. In the stage of convalescence or falling temperature the normal element returns apparently to the blood, and a corresponding destruction of bacilli takes place. Further, inasmuch as this marked destruction of bacilli must set free an excess of typhoid toxin contained in the bacterial cells, we have in this fact a possible explanation of the marked remissions of temperature seen clinically in the fourth week of the disease. 6. Inasmuch as the addition of normal serum to the inactive serum of the sick typhoid patient will, in most instances, make that serum more powerful, in fact, make it very similar to the serum found in the fourth week, we should be justified, theoretically, in treating such patients with normal serum. 7. It will probably be found, however, that in certain cases the blood of the patient will lack both immune and normal elements, both of which will have to be supplied. Just what elements will be necessary can be determined probably by submitting the patient's blood to tests similar to those just described. 8. The blood of a normal individual may, under conditions described above, have very marked destructive power upon typhoid bacilli. This power is due, undoubtedly, to substances very similar to those found in typhoid serum. Their relation to the subject of natural immunity is, of course, of the greatest importance, and needs much further study. 9. The principles set forth above may apply to infection other than typhoid. This question should be investigated."

111. **Bacillus Diphtheria.**—The morphologic varieties of bacillus diphtheriæ have been studied by Gorham, who finds that his results agree with those of Westbrook that "(*a*) Granular types are usually the most predominant forms at the outset of the disease. (*b*) The granular types usually give place wholly or in part to barred and solid types shortly before the disappearance of diphtheria-like organisms. (*c*) Solid types may sometimes be replaced by granular types when convalescence is established, just before the throat is cleared of diphtheria-like bacilli." He also adds the following: "1. That diphtheria-like bacilli are more frequent in the nose than in the throat. 2. That there are diphtheria-like bacilli in the noses and throats of a large percentage of apparently healthy persons. 3. That by a careful study and classification of the various forms of bacillus diphtheriæ, many morphologic varieties may be recognized. 4. That the change from the granular or barred type to the solid staining types seems to take place under the influence of the body fluids of a person immune or becoming so. 5. That the virulence of the bacillus diphtheriæ seems to be correlated with its microscopic form. 6. That the so-called xerosis, pseudo-diphtheria, or Hoffman's bacillus are morphological varieties of the bacillus diphtheriæ, sometimes capable of producing clinical diphtheria, but usually *non*-pathogenic for guinea-pigs. 7. That we do not know whether the solid staining types regain their virulence when once they have lost it, though this seems probable. 8. That *Neisser's stain* is of no value in differentiating the barred or solid types of bacillus diphtheriæ.

114. **Malta Fever.**—Curry reports four cases of Malta fever occurring in soldiers or sailors returning from tropical stations and calls attention to the value of the serum test in this condition. He concludes that Malta fever is a very widespread disease in tropical and subtropical communities. He suggests that the sedimentation test with micrococcus melitensis be added to the list of common routine blood examinations, especially in cases of persistent recurring rheumatism. It is possible that many of the fevers occurring in the South that are not typical malarial or typhoid, may be Malta fever.

121.—See abstract in The Journal of July 13, p. 135.

125. **Tubal and Ovarian Disease.**—Rothrock has been led from his own experience to believe that the radical operative treatment for removal of affected tubes is in most instances unnecessary if the infection is observed early and properly treated. A large number of the patients suffering from infection in these organs are highly neurotic and the reflex pain and hyperasthesia are all out of proportion to the local lesion, the removal of which does not cure the patient. He has, therefore, for some years followed the treatment published by him in the *Northwestern Lancet*, in January, 1900, consisting essentially in local treatment to the uterine cavity and daily observations of the same after-disinfection with corrosive sublimate, 1 to 5000 or of potassium permanganate 1 to 1000, following which an application of ichthyol, 50 per cent. in glycerin, formalin 25 per cent., of Grammatikati's mixture (alumnol gm. 2.5, tinc. iodin 25 c.c., alcohol 90 per cent. 25 c.c.). In case the infection is confined to the cervix that portion of the cavity alone receives attention. Dilatation of the os is done, if neces-

requires its removal, a wide resection should be undertaken as rapidly as possible, and the ends brought outside the abdomen; continuity should be restored at a subsequent operation. 5. In exceptional cases of enteric intussusception resection and immediate restoration of continuity gives the only chance."

Essential or Toxemic Dropsy; Dropsy Without Albuminuria. W. P. Herringham.—The cases of general anasarca occasionally met with, chiefly in children, but sometimes also in adults, which resemble Bright's disease but without albumin in the urine, are discussed by Herringham, who describes the condition, lack of constant lesions, apparently normal kidneys, etc., and asks whether it is a real nephritis. He says that both in the symptoms and in the etiology from exposure to cold and after scarlatina it closely resembles nephritis. There are also many cases of scarlatinal nephritis without albumin in which the kidneys show atypical lesions. There are, it is true, some cases of edema from anemia and occasionally cases of pernicious anemia will terminate with great general dropsy. Bristowe, Ashby and Wright apparently take the view that dropsy is dependent upon anemia, but in some cases anemia is not present, and in others it is by no means of that degree that should naturally account for the severe anasarca. It is not to be supposed that a grown-up man in full work and after getting wet through suddenly falls a prey to anemia such as to produce anasarca as sometimes happens in the adult cases of this condition. He holds rather to the view that the condition here is of microbic infection which may in some cases produce anasarca and nephritis and in other cases cause a form without disease of the kidneys. It is the toxic condition of the blood which is the common cause of both these conditions and nephritis.

Results of Tendon Grafting in Infantile and Spastic Paralysis. A. H. Tubby.—This author reports his experience with 11 cases of tendon grafting for paralytic talipes. In 6 there were good results and in 5 fair, meaning by the latter a partial improvement. In no case has failure resulted. Of the 4 operations in the forearm for spastic trouble, they had good results in 3 and partial in 1, and he says: "Tendon grafting is an operation with a future before it, and it has great possibilities, but it must not be employed indiscriminately. It is useless in cases of flail-like joints, where all the muscles are badly affected, and it should not be employed in slight cases of paralytic valgus or varus or in slight equinus, the last being easily remedied by section of the tendo Achillis. It is not an operation for the display of anatomical knowledge nor of mechanical skill in operating, but one requiring the nicest care in the selection of cases and of the muscles to be employed, and careful watching of the results of the operation for several years afterwards."

Discussion on the Early Diagnosis of the Acute Specific Fevers. F. Foord Caiger.—The symptoms and differential diagnosis of measles, scarlatina and roseola are noted by Caiger, who points out the conditions that may resemble these and the difficulties attending the bacteriologic test of diphtheria. He believes the Neisser stain is the most trustworthy criterion for the true bacilli diphtheriæ that we have, excepting, of course, the inoculation test. The question of the "fourth disease" that has been suggested as existing by Dr. Clement Dukes, he holds as still *sub judice*, but says it offers a legitimate field for discussion and investigation.

The Value of Widal's Serum Reaction in the Diagnosis of Typhoid Fever in Children. J. H. Thursfield.—The author has employed the Widal reaction in 100 different cases, in 42 of which it was positive; the remainder were negative, including examples of almost every febrile disease to which children are liable. In the 42 cases with the positive reaction, several were those in which the diagnosis would have been difficult without the test at the stage when it was made. Only one of these 42 gave a negative result later than the first week of illness. Allowing for the smallness of the figures he would claim that in children this positive Widal reaction is trustworthy evidence of the presence of typhoid and that negative reaction later than the tenth day of illness is strong but not absolute proof of its absence, while repeated negative reactions are trustworthy evidence that the case is not typhoid at all. The test is just as reliable in children as in adults.

Radical Cure of Inguinal Hernia in Children. Harold J. Stiles.—The operation preferred by Stiles in case of inguinal hernia in children is practically the Mitchell Banks operation. While he has no doubt of the value of Bassini's operation in adults, in children he advises as little interference as possible with the anterior wall of the canal. He speaks with commendation of the advantages of the Cleveland needle over the MacEwan needle in passing the sutures.

Two Cases of Chronic Hydrocephalus in Infants Treated by Tapping and by Introduction of Aseptic Air in the Place of the Fluid. Wm. Ewart and W. Lee Dickinson.—The provisional conclusions which the authors consider warranted from their observations here reported are: "1. With due precautions the fluid of chronic hydrocephalus may be completely evacuated from the yet unclosed skull of infants, and aseptic air may be allowed to take its place. This operation may be repeated without detriment and with scarcely more risk than belongs to the usual method of paracentesis. 2. In favorable cases of moderate effusion a single operation may suffice. Continued oozing from the puncture for a few days after the removal of the tubes is not unfavorable. 3. In cases of considerable effusion an obvious indication is to relieve the brain from the weight and from the pressure of the fluid. The evacuation is facilitated by the introduction of aseptic air. By a timely repetition of the operation a hydrocephalic infant might be enabled to carry the weight of the head, and, if the treatment were begun sufficiently early, permanent damage to the brain tissue might be averted and a normal development might perhaps ensue. 4. In large heads, whilst hydropneumocephalus persists a considerable splashing sound is readily obtained. There is obvious risk in eliciting this sound by forcible succussion and for the same reason any abrupt movement of the head should be avoided."

Diagnosis of Suppurative Pericarditis in Children. Frederick E. Batten.—While the diagnosis of suppurative pericarditis in children is a matter of considerable difficulty and the cases are commonly mistaken for tuberculosis and empyema, the special points are given by Batten as follows: "One may say that a fairly definite date can be fixed for the onset of the disease, the condition of the child generally bears a striking resemblance to that of a child suffering from empyema; the child is pale but not sallow, the limbs are wasted and the muscles flabby, and the skin is generally moist, and has not the dry and scaly conditions so often seen in tuberculosis. The children are extremely liable to severe and sudden attacks of syncope. The temperature has a generally irregular character, with rather sudden rises and sharp falls. The rapidity of the heart's beat is always great, and seemingly out of all proportion to the general condition of the child, who does not seem especially distressed. On physical examination of the chest the signs suggest either an effusion into the pleural cavity or tuberculous consolidation of the lung, but, as a rule, no increase of the area of cardiac dulness can be mapped out, although epigastric pulsation may be present. It might be suggested that the diagnosis might be assisted by the introduction of an exploring needle, but given symptoms or signs that would suggest pericardial effusion it would be much safer to make an incision in an intercostal interspace or resect a rib if necessary rather than pass an exploring needle toward the heart." Until diagnosis becomes more accurate, rational treatment, viz., the opening of the pericardium and draining the cavity is impossible. Even where it is possible the percentage of recoveries would be slight.

Observations on Suppurative Pericarditis in Children. George F. Still.—This author, discussing the same subject, believes that we can do something in the way of prophylaxis and in the majority of cases we have a pneumococcal exudation in the pleural cavity producing secondary infection, and early diagnosis with speedy evacuation of this infective matter may reduce the risk of pericardial infection.

sary, by sea-tangle tents. It is important that it should be patulous to secure drainage. When the tubes are involved the treatment is modified somewhat. The patient in the acute stage is treated with rest in bed and cold applications. Later local treatment directed to the tubes as well as the uterine cavity is advised.

126. **Cholecysto-Colostomy.**—The question implied in the title of this article is answered by Shimonek as follows: 1. That in all cases of malignant obstruction of the bile-ducts, the safest, easiest and quickest operation is advisable. The diversion of the bile into the colon alone can not cause enough physiologic distress in the time such a patient will live to be at all objectionable and its beneficial effects in relieving the jaundice and its toxic effects will materially lighten the sufferings of the individual. 2. He would advise anastomosis in all cases where the gall-bladder or duodenum or both are so adherent that approximation would be difficult, requiring extensive dissection often involving profuse hemorrhage. 3. He would make the union with the smallest button and as far away from the flexure of the colon as possible, and to avoid any possible forcing of bile contents into the gall-bladder, thus bringing on a possibly dangerous infection. 4. That the rationality of diverting the bile into the colon is so far sustained in all the operations reported.

130. **Uric Acid Fallacy.**—The theories of uric acid and its pathologic action in the system are reviewed by Billings, who quotes from Croftan as to its non-toxicity and that the alloxuric bases are the real cause of the toxic affections usually attributed to uric acid. Although we find no positive knowledge in regard to this subject, we are better able at present to throw aside a lot of theories and absurdities that have been too much enforced in the past and are still largely advocated by certain authorities.

133. This article has appeared elsewhere. See The Journal of September 14, title 58, p. 717.

140. **Congenital Dislocation of the Hip.**—The opinions of various authorities are first noticed by Bradford who finds from experience that a small number of cases of unilateral congenital dislocation of the hip may be permanently cured by the bloodless method with the exercise of ordinary skill, but that not more than one-half can be cured by even exceptional skill; that the percentage of skill is less in bilateral cases, but that some improvement in the gait can be expected in all. He also shows that by operative reduction with incision three-fourths of the unilateral cases can be cured between the ages of 3 and 8 years, and one-half of the bilateral ones, if treated with best skill. That in children of these ages stiffening is not to be expected unless suppuration follows; this complication can be avoided with care. The question whether the acetabulum should be deepened in order to prevent reluxation is noticed and in certain cases he has employed this method.

163. **Gallstones.**—Vaughan describes the different types of gallstones and their method of occurrence. He sums up in the following statement: "1. Chlosterin and a compound of bile-pigment and lime, generally designated as bilirubin chalk, either singly or together, make up the essential part of gallstones. 2. The cholesterin, which forms gallstones, is not that brought to the gall-bladder from the liver as a constituent of the bile, but has its origin in the mucous membrane of the bladder. 3. While both bilirubin and salts of lime are normal constituents of the bile, the chemical compound formed by the union of these substances and which enters so largely into the composition of gallstones, is not formed by the condensation of bile, but is formed, so far as we now know, only as the result of bacterial infection of the bile. 4. Gallstones are formed in the bladder or gall-ducts only when the mucous membrane of these organs is infected. 5. The infecting bacterium which leads to the formation of gallstones is in the majority of instances the bacterium coli commune, but it is probable that other micro-organisms may have a like effect."

164. **Gallstones.**—The diagnosis of gallstones and their clinical history is discussed by Metcalf who concludes that, though many signs and symptoms are usually present, the only positive sign is the discovery of the stone in the feces. When symptoms of disease affecting the bile passages are persistent, exploratory incision should be made to complete the diagnosis and at the same time to give relief.

172.—This article has appeared elsewhere. See The Journal of September 14, 189, p. 723.

177-178. **Mosquitoes in Their Relation to Disease.**—Beyer's article is a very thorough description of the characteristics of the pathogenic mosquitoes, with illustrations. Veazie describes the species found near New Orleans. He makes the interesting practical note that the mosquitoes are very fond of sucking amongst soiled clothing, the culex especially, and he thinks this fact may account for the dissemination of disease by fomites. He has also seen them imbibing the vomited and excreted matter from patients. In this case the male will suck up the blood as well as the female and he suggests that Drs. Reed, Carroll and Agramonte will be interested in this observation.

British Medical Journal, September 7.

What Is Intussusception? How Should It Be Dealt With? Edmund Owen.—Owen is of the opinion that intussusception is surgical from the very beginning and the medical treatment can afford no trustworthy means of managing the cases, that prompt abdominal section is the only scientific and practical way of giving relief. In conclusion, he maintains, "that whether a strangulation of the intestine is by an ensheathing piece of bowel or by the neck of a hernial sac, the effects are very much the same, and that delay in affording relief is likely to be fatal. Lastly, that the best way of affording prompt and certain relief is by the surgeon cutting down to the seat of strangulation and putting it right in a proper surgical way."

Discussion on the Treatment of Intussusception in Children. Bernard Pitts.—This author thinks inflation may be employed sometimes when the intussusception is along the transverse or descending colon, as a useful preliminary operation and will often limit the field of operation and enable the incision to be made directly through the swelling. Even if complete reduction should apparently take place it is generally best to make sure of this by a small incision, otherwise one must remain in doubt, as it is very probable that reduction is not quite complete and that it will recur or else give rise later to a condition of chronic stenosis. He remarks that it is essential in young children that the shock should be minimized by placing the child on a hot-water cushion and by having the extremities covered with cotton wool and bandage. The operation must be a rapid one. When the abdomen is much distended and the position of the tumor has not manifested itself it is best to make an incision in the middle line and take special precautions against prolapse of the small bowel. A distended coil may with advantage be withdrawn and air and intestinal contents allowed to escape through a small incision, this being afterwards closed; examination is thus rendered comparatively easy. This is much better than allowing the coils of distended and unmanageable gut to remain outside the abdomen during exploration. He dwells especially also on the importance of suturing the exploratory wound and the use of the buried suture and leaving superficial sutures as long as possible. While deep buried sutures add a little to the length of operation, they are better in young children, and he adds the following modifications of the conclusions offered by him in 1897: "1. Try inflation only when the case is seen within a few hours of onset, and is not of a very acute character. In the great majority of hospital cases it is better to open the abdomen at once. 2. Inflation may be tried in certain other cases for the purpose of reducing the main portion of the intussusception and enabling the incision to be made directly over the cecum. 3. When reduction is found impossible in chronic cases a resection may be generally done through an incision in the ensheathing bowel. 4. In acute cases, and especially if gangrene is present or the condition of the bowel requires its removal, a wide resection should be undertaken as rapidly as possible, and the ends brought outside the abdomen; continuity should be restored at a subsequent operation. 5. In exceptional cases of enteric intussusception resection and immediate restoration of continuity gives the only chance."

Essential or Toxemic Dropsy; Dropsy Without Albuminuria. W. P. Herringham.—The cases of general anasarca occasionally met with, chiefly in children, but sometimes also in adults, which resemble Bright's disease but without albumin in the urine, are discussed by Herringham, who describes the condition, lack of constant lesions, apparently normal kidneys, etc., and asks whether it is a real nephritis. He says that both in the symptoms and in the etiology from exposure to cold and after scarlatina it closely resembles nephritis. There are also many cases of scarlatinal nephritis without albumin in which the kidneys show atypical lesions. There are, it is true, some cases of edema from anemia and occasionally cases of pernicious anemia will terminate with great general dropsy. Bristowe, Ashby and Wright apparently take the view that dropsy is dependent upon anemia, but in some cases anemia is not present, and in others it is by no means of that degree that should naturally account for the severe anasarca. It is not to be supposed that a grown-up man in full work and after getting wet through suddenly falls a prey to anemia such as to produce anasarca as sometimes happens in the adult cases of this condition. He holds rather to the view that the condition here is of microbic infection which may in some cases produce anasarca and nephritis and in other cases cause a form without disease of the kidneys. It is the toxic condition of the blood which is the common cause of both these conditions and nephritis.

Results of Tendon Grafting in Infantile and Spastic Paralysis. A. H. Tubby.—This author reports his experience with 11 cases of tendon grafting for paralytic talipes. In 6 there were good results and in 5 fair, meaning by the latter a partial improvement. In no case has failure resulted. Of the 4 operations in the forearm for spastic trouble, they had good results in 3 and partial in 1, and he says: "Tendon grafting is an operation with a future before it, and it has great possibilities, but it must not be employed indiscriminately. It is useless in cases of flail-like joints, where all the muscles are badly affected, and it should not be employed in slight cases of paralytic valgus or varus or in slight equinus, the last being easily remedied by section of the tendo Achillis. It is not an operation for the display of anatomical knowledge nor of mechanical skill in operating, but one requiring the nicest care in the selection of cases and of the muscles to be employed, and careful watching of the results of the operation for several years afterwards."

Discussion on the Early Diagnosis of the Acute Specific Fevers. F. Foord Caiger.—The symptoms and differential diagnosis of measles, scarlatina and roseola are noted by Caiger, who points out the conditions that may resemble these and the difficulties attending the bacteriologic test of diphtheria. He believes the Neisser stain is the most trustworthy criterion for the true bacilli diphtheriæ that we have, excepting, of course, the inoculation test. The question of the "fourth disease" that has been suggested as existing by Dr. Clement Dukes, he holds as still *sub judice*, but says it offers a legitimate field for discussion and investigation.

The Value of Widal's Serum Reaction in the Diagnosis of Typhoid Fever in Children. J. H. Thursfield.—The author has employed the Widal reaction in 100 different cases, in 42 of which it was positive; the remainder were negative, including examples of almost every febrile disease to which children are liable. In the 42 cases with the positive reaction, several were those in which the diagnosis would have been difficult without the test at the stage when it was made. Only one of these 42 gave a negative result later than the first week of illness. Allowing for the smallness of the figures he would claim that in children this positive Widal reaction is trustworthy evidence of the presence of typhoid and that negative reaction later than the tenth day of illness is strong but not absolute proof of its absence, while repeated negative reactions are trustworthy evidence that the case is not typhoid at all. The test is just as reliable in children as in adults.

Radical Cure of Inguinal Hernia in Children. Harold J. Stiles.—The operation preferred by Stiles in case of inguinal hernia in children is practically the Mitchell Banks operation. While he has no doubt of the value of Bassini's operation in adults, in children he advises as little interference as possible with the anterior wall of the canal. He speaks with commendation of the advantages of the Cleveland needle over the MacEwan needle in passing the sutures.

Two Cases of Chronic Hydrocephalus in Infants Treated by Tapping and by Introduction of Aseptic Air in the Place of the Fluid. Wm. Ewart and W. Lee Dickinson.—The provisional conclusions which the authors consider warranted from their observations here reported are: "1. With due precautions the fluid of chronic hydrocephalus may be completely evacuated from the yet unclosed skull of infants, and aseptic air may be allowed to take its place. This operation may be repeated without detriment and with scarcely more risk than belongs to the usual method of paracentesis. 2. Recent Inquiries and Researches into the Poisonous Properties of Naphthalene and Aromatic Compounds. R. P. White and John Hay.—The poisonous properties of naphthalene and benzene compounds have been investigated by Hay and White, who find that probably the naphthalene group is much less dangerous than the benzene and toluene groups. Of the naphthalene compounds it is probable that the dinitrobenzene naphthalene is more poisonous than the mono-nitro preparation. The mono-nitro-benzene does not seem poisonous to cats, which appear to thrive upon it, but dinitro-benzene is exceedingly poisonous to both man and animals. The smallest lethal dose of dinitro-benzene for a cat of six pounds is 0.08 gram, given by the mouth in one dose; probably less than 1.82 gram would be fatal to man. Mono-nitro-toluene is quite inert when administered to cats, but nitro-toluene is too dangerous to work with, while the trinitro compound of toluene appears less dangerous than its dinitro-benzene equivalent. All these facts imply the administration either by the mouth or hypodermically, but the question has arisen whether dinitrobenzene or some of these other compounds can be absorbed through the skin in dangerous quantities. In manufactories where men work in these materials it has been suspected that they are dangerous by inhalation, and a German manufacturer who supplied fresh air entirely to his workmen so that they inhaled no vapor from the substances had, nevertheless, a certain amount of sickness amongst the employes and the only way in which the poison could get to the blood was through the skin. Hay has experimented on cats, shaving off the fur and insuring that there were no abrasions or cuts and applying dinitro-benzene ointment, carefully covering it with collodion. In three experiments the cats died within two or three days, or within a week. He also applied a small portion of a 25 per cent. dinitro-benzene ointment on his own skin and it produced decidedly uncomfortable symptoms lasting for over 48 hours, headache, tremor, high pulse, lividity of lips and nails, a feeling of fulness in the head, metallic taste, etc. The experiments prove conclusively that with dinitro-benzene within close contact with the skin it becomes absorbed. He points out the dangers of handling, grinding, heating and otherwise manipulating this material. Pure dinitro-benzene consists of colorless crystals, but the commercial substance is often darkened in color from impurities. In the working of these substances the workmen should avoid anything in the way of greasy appliances, unnecessary exposure of the skin, the hair of the head should be cut close and the face have as little hair as possible and caps close fitting, covering as much surface as possible. There is also a suggestion that the numerous oxidizing ingredients associated with dinitro-benzene in the manufacture of high explosives may also have some influence on absorption.

On the Prophylaxis of Carcinoma. C. B. Keetley.—Almost all primary carcinomas are situated in the breast, alimentary canal, skin, uterus or in the canals, ducts and glands subsidiary to these parts or directly opening into them. The medium which can carry cancer is, therefore, one which is liable to reach such situations, and Keetley has sought for this in water, which he thinks, however, is not likely to be a carrier. He considers milk much more dangerous in this respect, especially in producing cancer in the alimentary tract. He suggests also that flannel underwear may have something to do with the occurrence of mammary cancer, as it is handled more gently in the laundry than other fabrics and the germs are less likely to be destroyed. He asks for information as regards the possibility of guilt or innocence of butter, milk and cheese in the etiology of carcinoma and suggests the following rules for the prophylaxis of cancer: "1. Chronic inflammation, suppurations and especially ulcerations, should not be neglected or allowed to drift. Still better, commencing troubles of the kind should be treated promptly and not allowed to become chronic. With regard to ulcerations, especially of the alimentary canal, and with regard, also, to suppurations, especially of the breast, it is to be remembered that the cicatrices left by their cure are liable to become the seat of malignant infection. It is, therefore, doubly desirable to cure such ulcerations and suppurations in their earliest stage, so that little or no cicatricial tissue may remain, and in cases where the arguments for and against the removal, as opposed to the simple healing of an ulcer, are otherwise evenly balanced, the indication to remove a place especially liable to cancer should prompt one to excision. 2. Well-known sources of irritation of mucous membranes and of skin should be avoided, *e. g.*, smoking when any trace of soreness is discovered in the mouth, on the tongue, or on the lips, and the habitual use of strong condiments and spices. Workers in special trades, such as chimney-sweeping, should lose no time in having the smallest cutaneous rashes or other trouble promptly cured. Among milk-products cheese is itself an irritant to mucous membranes. Some syphilitics with a tendency to ulceration of the tongue, notice that a fresh attack frequently follows eating cheese. 3. A woman should allow nothing to come in contact with her nipples except smooth clean linen, cotton or silk, and the soap and warm water with which she washes herself. After being washed the nipples should be gently and thoroughly dried. She should not touch them with her hands or fingers at all. During lactation the nipple should be cleansed and gently dried after each act of sucking and then protected with a dry and clean covering. The nipple should be not merely withdrawn from the infant's mouth and pushed back under the mother's clothes. If wool be worn it should be sterilized by heat. 4. Whoever takes as food uncooked and unsterilized milk, butter and cheese should recognize that he does so at the risk of introducing into his system the germs of disease, and that among these disease essences, so to call them, may be that of carcinoma."

On the Behavior of Oxy-Hemoglobin, Carbonic-Oxid-Hemoglobin, Methemoglobin, and Certain of Their Derivatives, in the Magnetic Field. Arthur Gamgree.—The diamagnetism of blood was first observed by Faraday in 1845, and has since been remarked upon by other investigators. Gamgree has investigated the reaction to magnetism of oxyhemoglobin and comes to the following conclusions from his experiments: "1. The blood-coloring matter, oxy-hemoglobin, as well as carbonic-oxid hemoglobin and methemoglobin, are decidedly diamagnetic bodies. 2. The iron-containing derivatives hematin and acethemin are powerfully magnetic bodies. The differences in magnetic behavior between the blood-coloring matter and acethemin and hematin point to the profound transformation which occurs in the hemoglobin molecule when it is decomposed in the presence of oxygen. 3. The preliminary study of the electrolysis of oxy-hemoglobin and CO-hemoglobin renders it probable that in the blood-coloring matter the iron-containing group, on which its physiologic properties depend, is (or is contained in) an electro-negative radical; according to analogy the iron in such a compound would possess diamagnetic and not magnetic properties."

Indian Medical Gazette, August.

A Suggestion for the Surgical Treatment of Chyluria and Other Forms of Filarial Lymphatic Varix. Patrick Manson.—The following suggestion, which was offered by Manson in a case of persistent chyluria, is here given by him to the public. The disease was evidently slowly killing the patient and had resisted all treatment. As not infrequently happens the patient had varicose groin glands. It occurred to him that tension in the lymphatic varix, the rupture of which into the urinary tract was the source of the chyluria, might be relieved and the rupture healed, could the varix by surgical means be induced to empty into a vein. He therefore suggested to the patient to have one of the dilated lymphatics dissected out under asepsis, cut across, and telescoped into some neighboring and convenient vein which would have to be slit up for a short distance for this purpose. In this way he thought that by short circuiting the path of the regurgitating chyle the chyluria might be cured and the patient's life saved. He offers this suggestion to Indian surgeons who have better opportunities for following it up than he has in Great Britain.

Relation of the Entero-Coccus to the Etiology of Tropical Dysentery. E. D. W. Greig.—The entero-coccus described by Thiercelin in 1899 as found in normal stools in which it appears to lead a saprophytic existence, is here described. Two observers have recently been working on the relation of this organism to the etiology of non-tropical dysentery. Simonin found its presence in a large number of cases occurring in Paris, and Lewkowiez describes the microbe and considers it possibly the organism of some cases of non-tropical, and even of tropical dysentery. He investigated several cases and in two of them he got the entero-coccus in the stools in great abundance, and in the third, which was complicated with meningitis, he obtained the organism in pure culture by lumbar puncture. He considers it related to the pneumococcus and found it in the stools partly enclosed by phagocytes in the form of diplococci or short chains of four to eight. In the latter the cocci are arranged in pairs and the opposing surfaces are broad and close to one another. On agar they grow as single cocci, sometimes as pairs. A certain amount of point at the free ends resembling the pneumococci is sometimes seen; most possess a broad delicate capsule. In broth they grow out in long chains; the capsule is well developed, and encloses single cocci, pairs of cocci, or certain sections of the chains. In the animal organism the entero-coccus occurs as a diplococcus with well-marked capsule, and sometimes it takes the form of streptococcus. It stains by Gram's method. It differs from the pneumococcus in its more rounded form and breadth, and forms longer chains in the broth. On artificial media it resembles the pneumococcus, the colonies are longer and more slimy, very transparent and tend to run together. In milk, after a time, coagulation takes place. It is pathogenic to mice and rabbits, producing local inflammatory lesions with slight toxic or septic action, agreeing well with the clinical picture of dysentery. In Greig's preliminary observations, he reports finding in tropical cases organisms that seem to him identical with those of Lewkowiez, associated with other bacilli, however, and he considers the constant occurrence of this organism in acute dysentery and in the production of phagocytes, lends support to the proposition that it is causally connected with the acute dysentery of the tropics. In simple diarrhea, personal examinations with a view to determining the presence of this organism were negative. He thinks it quite likely that it may exist as a saprophyte under normal conditions, but from any cause that lowers the local resistance or increases its virulence, a pathologic condition of dysentery is produced.

Presse Medicale (Paris), August 24 and 31.

Surgical Treatment of Hydatid Cysts in the Kidney. E. Albarran.—Of the seven patients treated by trans-peritoneal nephrectomy which Albarran has collected only two survived. On the other hand, all the three patients treated by nephrectomy by the lumbar route, have recovered. Consequently, nephrectomy by the latter route does not deserve the discredit into which nephrectomy in general has fallen. Albarran describes his personal case in detail, and summarizes the indications as follows: If a laparotomy has been done on a dubious diagnosis, conclude with nephrostomy unless under exceptional circumstances. Houzel's fourteen and Albarran's twenty-three patients all recovered. If the intervention is by the lumbar route, with or without an established diagnosis, open the cyst, evacuate, and determine the possibility of exterminating the germinative membrane in order to proceed to capitonnage. If this is impossible, examine the kidney, and if it is still useful and it is possible to extirpate the cyst in toto, proceed to a resection of the kidney. If the organ is still useful and the above operations are impossible, continue with nephrostomy after partial resection of the cyst. But if the kidney is so damaged that it is totally incapable of future functional activity, try to detach it and, if possible, conclude with nephrectomy. If the adhesions are too solid and numerous for this without too much destruction of tissue, and especially if the patient is not in a condition to bear such an extensive operative traumatism, restrict the intervention to nephrostomy.

Cacodylic Medication. A. Martinet.—Both experimental and clinical research and experience confirm the general stimulation of the organism and of its functions that follows administration of arsenic. Experience has also demonstrated the correctness of Gautier's assertions in respect to the remarkable non-toxicity of one of its derivatives, cacodylic acid. As long ago as 1841, Bunsen announced that a large amount of this acid could be injected into a rabbit's ear without intoxication, and he consequently classed it as a non-poisonous substance. Only two cases of disturbance following its administration have been reported, one was in a patient with cancer of the liver, and consequently, hepatic insufficiency for the present must be accepted as a contra-indication. The other was a tuberculous patient who took 20 cg. of sodium cacodylate by the mouth during the day in three pills. Symptoms of arsenical poisoning were evident after the eleventh pill. Normal conditions were restored after suspension for three days. (*Brit. Med. Jour.*, 1900, ii, p. 1823.) The chemical and biologic properties of arsenic are so altered in cacodylic acid that it is impossible to detect it by the usual reagents for arsenic. Impurities must be guarded against. The absence of poisonous arsenites and arseniates in sodium cacodylate is indicated by the lack of precipitation when an excess of lime water mixed with baryta water is added. The most important test for the presence of arsenites and arseniates is the addition of hydrochloric acid to an aqueous solution. There should be no yellow precipitate from the formation of arsenic sulphide by the action of hydrosulphuric acid. These impurities may have been the cause of the intoxication mentioned above. It is prudent to commence with small doses—2.5 to 5 cg. of sodium cacodylate—and gradually increase to 10 cg., which is a good average dose. There does not seem to be any particular advantage from using larger doses. The subcutaneous method is preferable. Administration by the mouth or rectum should be reserved for cases in which the former is impossible owing to the distance from the physician, or the timidity of the patient. Gautier absolutely rejects any but the subcutaneous route, but this is a little too sweeping. Comparative case-reports show that the best results have been attained by suspending the medication for a week between each series of eight to twelve injections, without waiting for symptoms of intolerance. A good prescription for subcutaneous injection is Gautier's: 6.4 gm. of pure sodium cacodylate, and ten drops of a 10 per cent. alcoholic solution of carbolic acid, in 100 c.c. of distilled water. When necessary to administer it by the mouth, Martinet prescribes 50 cg. of sodium cacodylate in 100 gm. distilled water. A teaspoonful contains 2.5 cg. of sodium cacodylate. One or two teaspoonfuls should be taken in the middle of the two principal meals in a glass of some beverage. It can be made into a pill by the following formula: sodium cacodylate 2 cg.; benzoin and licorice powder each 1 cg., and one drop of 90 per cent. alcohol. For rectal injection, one or two teaspoonfuls of an aqueous .5 to 1 per cent. solution of the sodium cacodylate. This is equivalent to 2.5 to 5 cg. of the active substance. One or two tablespoonfuls of boiled water are added, and, if needed, two or three drops of laudanum. The onion odor of the breath is particularly frequent in children, and often in those who are deriving great benefit from the medication. Gautier considers it an indication of the formation of cacodyl oxid and other toxic substances, but clinical experience does not sustain this view. The onion odor was not mentioned in the case of intoxication mentioned above. (See The Journal of August 24, p. 539.) Rocaz lauds this cacodylic medication especially for children. He prescribes 1 cg. a day at 3 years of age, 2 at 6, 3 at 9; 4 at 12, etc. Martinet has found doses of 3 to 10 cg. very beneficial for children between 6 and 12, with no indications of intolerance, except the onion odor. Josias is accustomed to give the children in his service as much as 10 to 15 cg. a day.

Berliner Klin. Wochenschrift, August 19.

Association of Tetany and Epilepsy. A. Westphal.—A woman of 42 with chronic epileptic idiocy exhibited a permanent tonic contracture of the muscles. Another patient exhibited symptoms of tetany the second day after a partial strumectomy. It was followed by cachexia strumipriva and double cataract. Six months after the operation, epileptic seizures appeared, preceded and outlasted by typical tetanic convulsions. The seizure was a mixture of tetany and epilepsy. There were no further attacks after six days of thyroiodin treatment until dismissal, six months later. On suspension of the thyroiodin, however, the seizures recurred, requiring the continuance of the treatment, which had cured the apathy and other psychic disturbances at the same time as the other troubles. Both the tetany and the cataract formation are probably nutritional disorders, due to the action of toxins, similar to the trophic disturbances observed in certain nervous affections. The toxins probably originate in the products of morbid metabolism.

Centralblatt f. Bakteriologie (Jena), July 12 and 18.

The Autosterilization of the Intestines. J. H. F. KOHLBRUGGE.—Many scientists have noticed that in animals the small intestine is sterile, but Kohlbrugge is the first to explain this phenomenon as due to a process of autosterilization. The intestinal secretions are bactericidal, he states, and all bacteria coming in contact with the secreting wall are destroyed under normal conditions. The benefits derived from saline purgatives, etc., are probably due to the augmented secretion which they induce. The bactericidal properties of the intestinal juices are, of course, derived from the blood. Experiments on isolated loops of the intestines showed that the bacteria increased enormously in numbers if the circulation was arrested, while they were rapidly destroyed if the circulation was maintained. Readers of THE JOURNAL are familiar with Kohlbrugge's assertions that every intestine has its individual colon bacillus. and that the appendix may be the nesting-ground for these specific bacilli. The colon bacilli taken in the food are probably killed in the stomach, the same as the home-grown colon bacilli, if they happen to find their way into the stomach. Rabbits eat their feces and they become sterilized in the stomach. With sterile food and sterilization of the mouth, all the wild, imported bacteria may be killed, but one's own colon bacilli are not influenced, and sterile feces should not be expected. In health, the intestinal putrefactions depend exclusively upon one's own bacilli of putrefaction in the large intestine. The bactericidal power of any substance ingested should not be calculated on the basis of the bacteria in the stools, as the numbers vary widely even in health, and a few millions more or less are of little consequence. The ordinary microbes in the feces are harmless and the clinical importance of putrefaction in the intestines has been exaggerated. It is also to be borne in mind that intestinal disinfectants do not affect the products of the metabolism of the bacteria. Purgatives and a milk diet are the only sure means of diminishing putrefactive processes. When the intestinal wall is an actively secreting membrane, it is impermeable for bacteria, but all processes which interfere with its secreting power are liable to render it permeable for micro-organisms, both wild and home-grown. Bacteria pass more readily from without into the intestine than from within outward. Injected under the skin or into the blood, they may soon be detected in the intestines. The walls of the latter seem to be powerless against them, possibly because the vital functions in general have already become depressed by infection from them. The chemical, fermenting action of the home-grown bacilli in the intestines might possibly be dispensed with, but they evidently are useful in stimulating peristalsis and in checking the development of other more harmful bacteria by their acid reaction. Their gaseous products may also influence the statics of the intestines and, indirectly, the movements of the diaphragm. The antagonism between the home-grown and the wild bacteria is probably their most important function. The small intestine has no home-grown bacteria or, if any, they are of the colon bacillus group. The cecum is the shelter of the typical, individual, colon bacillus and the rectum, of the putrefaction bacteria, like the putrificus, proteus and subtilis and also the acidophilus group, which are probably akin to diphtheria bacilli. The individual colon bacilli are only to be found elsewhere in the lower portion of the ileum. Those found in the jejunum are a branch variety and those in the colon are modified by contact with the putrefaction germs. The pancreatic juice and the bile have little if any bactericidal power. The autosterilization of the intestines occurs only *in vivo* and can not be studied on the isolated secretions. This communication is based on extensive personal research and study of the works of others, who have discovered many of the facts but have failed to interpret them from this point of view.

Centralblatt f. Gynekologie (Leipsic), July 27.

Treatment of Chronic Exudates in the Pelvis with Hot Air. O. POLANO.—This rapid and powerful stimulant of resorption has proved extremely effective in Polano's experience applied to the pelvis for the treatment of chronic exudates. In one of his numerous cases the patient was cured of a hard exudate, palpable from the ilium to the umbilicus, which vanished entirely in the course of twenty applications of the hot-air apparatus. He found it particularly valuable in promoting resorption after evacuation of a pus pocket. It always relieved the pain immediately. Advanced pregnancy in one of his patients was not affected by the hot-air treatment which was applied in this case to relieve edema of the labia.

August 10.

The Mercury-Air Colpeurynter and Colpeurynter Massage. L. PINCUS.—The long-sought means of effective ambulant treatment of various chronic gynecologic affections is obtained by means of the vaginal colpeurynter filled with mercury or air, which Pincus recommends after three years of thorough trial in both dispensary and private practice. It is the perfection of the weighting-down treatment which he has long advocated, as it allows the weighting-down to be done so gradually, and removed in the same way by fractions of a millimeter, while it is simple and inexpensive. In pelvic lesions located near the pelvic floor, this measure is the chief factor in treatment and compression of the abdomen by bandages the adjuvant, but in lesions above, the latter is the main factor and the vaginal weighting-down and massage the adjuvant. The apparatus consists of two balloon-shaped colpeurynters, connected by tubes with a central, graduated, glass ball-shaped vessel. Two other tubes are also attached to the glass vessel, one connecting with an air bulb and the other admitting filtered air. The four tubes—each with its stopcock—form an X, with the glass ball in the center. One of the colpeurynters is empty and one is filled with mercury. The empty one is inserted in the vagina, then, by raising the colpeurynter filled with mercury, the latter flows into the graduated glass vessel in the center, from which it is gradually allowed to flow into the colpeurynter in the vagina until it holds 1000 to 1500 gm. of mercury. In cases of parametritic exudates and in all processes with effusions located on or near the floor of the pelvis, chronic in character, this intravaginal treatment with the mercury colpeurynter is a most valuable measure. It must be supplemented by compression of the abdomen. In case of lesions near or above the pelvic inlet, intravaginal massage is the adjuvant to compression of the abdomen. For massage purposes, the vaginal colpeurynter is filled with air instead of mercury; the tube is closed with the stopcock, the rest of the apparatus removed, and the end of the tube is turned up and fastened to the patient's clothing above. She is then dismissed for two or three days. If the pressure is too great the wearer can release a little of the air by turning the stopcock. This treatment has proved exceptionally useful in case of vaginismus, as the empty colpeurynter can be introduced through the smallest aperture, and after it has accomplished the dilation of the vagina, local treatment of the underlying gonorrhea or other cause can be instituted without delay. It has also cured many inflammatory conditions of the pelvic muscles, numerous so-called neuralgic affections of the region, weakness of the muscles entailing chronic constipation, and hemorrhoids. It is a much more effective stimulant of labor pains than the water colpeurynter. Pincus has waited before publishing his experience until thoroughly convinced of the exceptional benefits to be derived from the mercury and the air colpeurynters and recommends them now with confidence. This preliminary communication is soon to be followed by the detailed report of his experiences in the *Sammlung Klinischer Vorträge.*

Berliner Klin. Wochenschrift, August 26.

Hydatid Cyst Simulating Acute Pleuropneumonia. P. K. Pel.—The clinical picture was that of acute pneumonia of the middle lobe of the right lung and extensive pleuritis without effusion, complicated by a pleural effusion on the left side. The only missing symptoms were the pneumonia-sputum and facial herpes. The protracted course was attributed to the general debility from a vagabond life and alcoholism. An operation confirmed by autopsy soon afterward, revealed a hydatid cyst in the upper lobe of the right lung and the remains of a similar cyst in the left, surrounded by inflamed lung tissue. The first cyst was isolated, but the other communicated with a bronchus, and the acute symptoms had probably been caused by infection by this route. The physical signs on the left side were thus explained by the empty cyst and the compressed and inflamed lung tissue; on the right, by the crowding of the lung tissue by the deep-seated cyst.

Treatment of Heart Disease by Compression. M. Mendelsohn.—The painful sensations in heart disease are frequently located in the thoracic wall rather than in the heart itself. The pressure of an abnormally movable, hypertrophied heart pounding against the wall is almost sure to be painful. Elastic compression of the heart—which Mendelsohn has been advocating for some time, abolishes all these painful sensations while it relieves and favors the functional activity of the organ.

Deutsche Med. Wochenschrift (Leipsic), August 22.

Accidents and Diabetes. F. Hirschfeld.—The direct influence of trauma on the origin of diabetes is unmistakable in many instances. They are usually cases of nervous diabetes and a direct action on the nervous system can be assumed, as in the traumatic glycosuria described by Claude Bernard. It is possible, also, that the development of diabetes in case of an existing affection of the pancreas may be traced to the trauma. It may likewise induce an affection of the pancreas, such as cysts or hemorrhage or possibly a chronic inflammation. An already existing diabetes may take an unfavorable turn in consequence of a trauma. Coma is the most important of the aggravations from this source. In severe cases of diabetes a very slight cause may suffice to induce coma—so slight that it is difficult to decide whether it may not have been the natural consequence of the disease. Occasionally the accident may induce coma even in a mild case of diabetes. Death in such a case can be unconditionally ascribed to the accident, as coma very rarely appears in mild cases. Death under these circumstances does not occur for ten days after the accident, while in the severe forms of diabetes it follows in one or two or, at latest, four days afterward. It is probable that an accident may transform a mild and insignificant vascular affection into conditions that favor gangrene in the cases in which it appears consecutive to trauma. Hirschfeld concludes by calling attention to the inadvisability of much muscular exertion in the case of diabetics in general. Their capacity for muscular exertion is much diminished as a rule, and they should select occupations which do not call for severe physical efforts.

Scrofulosis and Tuberculosis. H. Neumann.—Investigations of Berlin school children undertaken by Neumann and several specialists, showed that 89 per cent. were scrofulous. He considers that they are all tuberculous and that the tuberculosis is the primary affection, causing the scrofulous manifestations by its toxins.

August 29.

Abscesses in the Rectus Muscles in Typhoid Fever. L. Bollack.—In abscess-formation in typhoid fever, the bacilli always seem to have lost their virulence to a great extent. The abscesses usually appear during convalescence and are symmetrical. A degenerative process seems to occur constantly in the rectus muscles, probably a granular or waxy degeneration, which renders the tissues very fragile. During some effort to cough they are liable to rupture, with consequent hemorrhage, and, in rare cases, to suppurate, by the action of the typhoid bacillus alone. Pyogenic properties are probably acquired by the bacilli only as they become attenuated. The discovery of typhoid bacilli in an abscess or empyema is therefore an indication not to be hasty in operating. In a case described, an abscess in the rectus was evacuated and pure cultures of the typhoid bacillus derived. In the course of a week a symmetrical abscess formed which was not interfered with, and it was spontaneously resorbed in the course of a month.

Deutsche Zift. f. Nervenheilkunde, xix, 2 to 4.

Pathologic Changes Induced by Lumbar Puncture. V. P. Ossipow.—The withdrawal of the cerebrospinal fluid in dogs by lumbar puncture causes a persistent hyperemia in the vessels of the meninges and even of the brain and cord. Repetition of the puncture leads to the production of numerous punctated hemorrhages. When the urine is aspirated, the hemorrhages are still more pronounced. The nerve cells are likewise affected, not only by lesions of the cells from the hemorrhages, but by the altered relations between the circulation and the nutrition of the cell.

Muenchener Med. Wochenschrift, August 27.

Etiology of Erysipelas. Jordan.—Acute osteomyelitis is usually the result of staphylococcus infection, but it has been proved that it may be produced by streptococci, pneumococci and typhoid bacilli. In the same way, erysipelas may be the work of the staphylococcus aureus or possibly of the pneumococcus or colon bacillus, but in general, it is the result of infection with the streptococcus. It has been produced on rabbits' ears by all these various micro-organisms. The parallelism with acute osteomyelitis is rendered more striking by the fact that the latter is usually a suppurative, but may be occasionally a serous or hemorrhagic-septic inflammation, while erysipelas is usually a serous inflammation, but may be accompanied by suppuration and even by gangrene. Both affections vary in intensity and either may terminate in pyemia and sepsis induced by the same causal agent.

Neurologisches Centralblatt (Leipsic), August 16.

Regeneration of Spinal Cord. A. Fickler.—In 1899 Fickler published two cases of compression of the spinal cord from caries of the vertebræ, in which he found a number of delicate, well-constructed nerve fibers emerging above the point where the compression had been located, and returning into the cord below. As no such fibers occur normally at these points, and as one case had showed marked improvement in the symptoms after the affection had persisted a certain length of time, he accepted them as newly-formed fibers, evidences of a regenerative process on the part of the spinal cord. Bielschowsky has recently published a similar discovery in a case of compression of the spinal cord. The fibers emerged from the region of the anterior commissure, in the sheath of the pia just above, and returned into the spinal cord just below the compressed region. He considers them a split-off portion of the pyramidal tract. No improvement had been noticed in the symptoms in the case. He also asserts that the fibers observed by Fickler must have been of the same nature. The latter points out that such fibers have never been discovered except at the compressed point, and he claims Bielschowsky's case as a typical instance of the regeneration of the spinal cord. The circumstances were unusually favorable for such an occurrence, as the compressing exostosis did not seem to have increased in size during the latter portion of the time. The first symptoms had been noted two and one-half years before death. The conditions of cure, he states, are the possibility of the restoration of normal circulation of lymph and of the development of new myelin sheaths around the axis cylinders which have remained uninjured, although their sheaths may have degenerated, and thirdly, the regeneration of nerve fibers. The first factor alone may be sufficient in many cases, others may require the co-operation of another or of all.

Pflueger's Archiv (Bonn), August.

Physiology of the Suprarenals. H. Strehl.—The removal of one suprarenal from an animal does not cause disturbance, but ablation of both was inevitably fatal in the experiments on 114 animals described. All attempts to transplant a suprarenal met with failure. Severing or compressing the vein of the remaining suprarenal, after removal of the other, always entailed the same result as the extirpation of the organ—that is, the blood pressure invariably fell. After cessation of the compression the blood pressure rose again. No substance could be discovered in any other organ that has this power of increasing the blood pressure.

Therapie der Gegenwart (Berlin), August.

Subarachnoid Antitoxin Treatment of Tetanus. E. v. Leyden.—It has been established that tetanus antitoxin will neutralize the tetanus toxin in the blood, but the persistence of the convulsions, after this has occurred, indicates that they are due to the localization of the toxin on the large motor ganglion cells of the anterior horns. An emulsion of these cells from a patient who had died in spite of the subcutaneous injection of antitoxin, induced experimental tetanus while tests with the blood were negative. Injecting the antitoxin directly into the brain has saved only 6 out of the 24 thus treated to date, according to the records. Kocher has obtained slightly better results by slowly instilling it after trephining, introducing the canula for 4 or 5 cm. Jacob and Sicard first tried subarachnoid injection, or dural infusion as they call it, after finding it very successful in tests on dogs, although it always failed on goats. This method has been tried eleven times on man. Six patients could not be saved, but the last five—although very severe cases—have all recovered, including a new case described by Leyden in this communication. The patient was a young hostler with temperature of 105.8 F. Duration of incubation not known, but symptoms of tetanus for three days. The temperature dropped to 101 F. in an hour after 10 c.c. of cerebrospinal fluid had been withdrawn and 5 c.c. of Behring's tetanus antitoxin infused in its place. The improvement was marked the next day, but the day after, the muscular rigidity becoming more pronounced, the infusion was repeated under the same conditions. By the end of the month the patient was completely restored except for persisting rigidity of the abdominal muscles which gradually subsided. The amount of antitoxin injected was equivalent to .5 gm. of the solid form. In Leyden's first case, two years ago, a young woman with tetanus of ten days' incubation, after a three months' abortion, recovered after dural infusion of the equivalent of 2.5 gm. of the solid antitoxin. The technique is the same as for lumbar puncture, but the patient must be kept under the influence of narcotics, and the food must be supervised as the patients are liable to choke. [Pfaundler has recently reported three cases of tetanus neonatorum treated in this way at Escherich's clinic, in which the beneficial influence of the dural infusion of antitoxin was unmistakable. McCaw has also published a recovery from tetanus neonatorum, with temperature of over 106 F., after subcutaneous injection of 5 c.c. of antitetanus serum from the Institut Pasteur. Pure cultures of the tetanus bacillus were derived from the navel secretions. Half the amount was injected again the third day, six days after the first symptoms had appeared.—Ed.]

Test of the Permeability of the Nose. Glatzel.—A small metal mirror is held against the lip just below the nose and the patient breathes on it. The moisture from the breath spreads out on it like a butterfly's wings and gives an accurate picture of the amount of breath passing through the nose. In case of unilateral obstruction, the disproportion is striking between the two sides of the picture. A few concentric arcs are engraved on the mirror for convenience. It is cut to fit close against the lip and to be used on the four sides.

Wiener Klin. Rundschau, August 25.

Treatment of Vertigo. R. Spira.—A concussion is liable to separate the terminal fibrils of the neurons innervating the labyrinth, and thus induce disturbances in hearing and in equilibrium. With repetition of the external excitation the vestibular nerve becomes deadened and less sensitive and the clinical disturbances in equilibrium become proportionately less and less pronounced. Spira therefore advocates as a treatment for vertigo, the systematic repetition of the external estimulation. This can be accomplished by daily gymnastic exercises, swinging the head up and down, to and fro and from side to side, and turning in circles around a chair or table, proceeding very gradually. This will cure the tendency to symptoms suggesting seasickness which many persons experience when they ride backward, swing or waltz. It has proved particularly efficacious in cases of vertigo consecutive to concussion of the labyrinth.

September 1.

Fixation Abscess in Puerperal Septicemia. Jansen.—A febrile parametritis following a spontaneous birth resulted in two abscesses in the gluteal region on each side of the sacrum. Fever persisted after evacuation and the spleen and liver remained hypertrophied, although the parametritis was almost cured. The temperature was not affected by quinin. The pulse increased to 145 and the patient became delirious, with chills. Two grams of oil of turpentine were injected under the left deltoid muscle, producing a fixation abscess. As it developed, the symptoms vanished and the patient rapidly and completely recovered. The case is described more fully in the *Niederlandischen Med. Wochenschrift.*

Nasal Therapy of Neuroses. L. Kuert.—While holding a 9-year-old boy who was having convulsions in the course of severe whooping cough, Kuert tested the corneal reflex and noticed that the cramp in the larynx unmistakably moderated as the cornea was touched. The whoop diminished in intensity, and as the eyelid was pressed against the eyeball, it became less and less, and ceased entirely when the conjunctiva was gently rubbed with the finger. This discovery of the close connection between the throat organs and the terminals of the trigeminus nerve was confirmed by further tests. The spasm of the glottis was completely arrested by tickling the mucous membrane of the nose with a feather. Further tests and experiences with other patients completed the demonstration of the inhibiting influence on spasms of the glottis, larynx and neighboring muscles of mechanical irritation of the terminals of the trigeminus. He has utilized this discovery during the last ten years in the treatment of spasm of the larynx, pharynx, lids, yawning spells, facial spasms, spasmus nutans and even in the uncontrollable vomiting of pregnancy, with almost invariable success. In very few of these cases was the nasal membrane pathologically altered. Besides the simple measures above mentioned, rubbing the cornea with the finger, tickling or holding the nose, he has used a snuff of quinin and sugar, or a 1 or 3 per cent. mentholized salve. A more energetic measure is a snuff containing a little veratrum album and Venetian talc. He uses quinin or a very small amount of the first snuff in the case of infants. Two cases of spasmus nutans were thus cured, also a number of obstinate cases of blepharospasm in older children. He prefers for the latter a salve of 30 cg. of mercur. precip. flav. in 15 gm. of vaselin. A pledget of cotton impregnated with this salve is inserted in each nostril alternately. The result was like magic in several instances. In one case the little patient, a boy of 5, suffered also from enuresis nocturna which vanished with the blepharospasm. Two mild cases of facial spasm were cured with a mentholized salve, and several of tic convulsif with the snuff. Yawning spasms which had resisted months of other treatment, ceased completely after a few days of the snuff. Laryngeal spasms on a basis of hysteria promptly yielded to the snuff. A severe and obstinate case of vomiting in pregnancy was controlled by it. It even had a perceptible inhibitory influence in a few cases of epilepsy. One young man found himself able to abort a seizure by introducing a crab's-eye into his own conjunctival sac whenever he felt the approach of an aura. In this way he was able to abort all seizures for several months, after which the reflex seemed to lose its inhibiting power. This treatment had no effect in nervous cough or nervous asthma. In fact they could be induced by it, but never inhibited. A patient with chronically recurring hay fever took the snuff as a preventive measure a fortnight before the usual date of its appearance and passed through the summer without the usual symptoms.

Wiener Med. Wochenschrift, June 22 and 29.

Etiology and Signs of Enteroptosis. J. Csemi.—Many assert that nervous dyspepsia and enteroptosis are identical.

that is, the cause and the symptoms are the same in each. Stiller has called attention to the mobility of the tenth rib as a sign of a congenital tendency to enteroptosis. He calls it the stigma of enteroptotic neurasthenia as it not only accompanies every case of pronounced enteroptosis, but is an index of the extent of the morbid process. Cseri states that he has noticed that patients of this category always present pronounced lordosis. The pelvis projects, the lumbar region hollows inward and the buttocks project upward and backward more in a horizontal plane. This deprives the abdominal organs of the natural supports supplied by the normal, more vertical position of the lower portion of the trunk. He adds this tendency to lordosis to the other stigmata of enteroptotic neurasthenia—the loose tenth rib and the long thorax. [Zweig reports in the *Archiv. f. Verdauungs.* vii, 3, that the loose tenth rib is not exclusively limited to nervous dyspepsia, as he has observed it in a few patients who have never had any symptoms of this particular form of dyspepsia.—Ed.]

Puerperal Gangrene of the Legs. E. Mandl.—In the twenty-two cases of puerperal gangrene which Mandl has collected, the gangrene made its appearance during pregnancy in four, and great compression of the pelvic veins during the course of the pregnancy was noticed in several others, especially his own personal case and Wormser's. In both of the latter the physician was sued for damages by the family, but the courts dismissed the suit. In his case, a healthy, vigorous primipara, after a spontaneous birth with complete laceration of the perineum, exhibited signs of phlebothrombosis with indications of gangrene, affecting both legs, on the seventh day. When the right leg was amputated all the vessels, both veins and arteries, were thrombosed from the foot to the lower third of the thigh, so that circulation was completely suspended. In the cases on record only 2 were bilateral. Heart disease was evident in 2 and suspected in 1. All recovered except 2, one of whom succumbed to pneumonia after amputation. Physicians should be on the lookout during pregnancy for conditions suggesting possible future gangrene.

Treatment of Tuberculosis by Mechanically Induced Hyperemia. A. Schenk.—Persons with a tendency to tuberculosis usually have large lungs and a small heart. The heart is unable to keep the lungs adequately supplied with blood, and the apices, where the circulation is most deficient, are the points usually first affected by the bacillus. Schenk combats these conditions by mechanically inducing hyperemia throughout the lungs, most intense at the apices. He accomplishes this by having the patients recline on an inclined plane, the feet higher than the head, all day long, out of doors in dry weather. He supplements this position-treatment by a hollow, rubber jacket allowing circulation of hot water at 113 F., which is worn for several hours morning and evening. An attendant sponges off the feet, hands and abdomen every five minutes with cold water. At the slightest indication of cardiac insufficiency, he has an interposed coil of tubing in which cold water circulates, placed over the heart. The effect of these measures on the expectoration and other symptoms is surprisingly favorable, especially after sleeping with the head low all night.

Gazzetta Degli Ospedali (Milan), August 25.

The Mosquito Theory of Yellow Fever. G. Sanarelli.—Since Sanarelli returned to the chair of hygiene at Bologna he has continued his studies of the icteroid bacillus, and remarks now that it would be far better for the cause of science to have this bacillus studied in laboratories at home, rather than to send susceptible and inexperienced men to study the disease in its haunts to die like young Meyers. The icteroid bacillus has been isolated for four years according to the strictest rules of bacteriology; it is at the disposal of any who wish to test it; it reproduces in animals exactly the same symptoms and lesions as yellow fever in man—according to the testimony of every one who has seriously investigated it—and it thus responds to all the conditions and requisites which should characterize the specific agent of yellow fever. One experience on man or, better still, one auto-experience would be worth more than all the theories and discussions in the world. He cites history to show that contagion has occurred in Philadelphia, Baltimore and other places where yellow fever is unknown, from contagion by means of garments formerly worn by a yellow-fever subject, but which had been packed away in trunks for two, five and even seven years. He states that yellow fever has appeared at Cuzco, Caraccas and other South American points thousands of feet above the level of the sea, far above all mosquito-breeding swamps. It even crossed the Andes and infected mountainous regions in Peru, at altitudes of 13,500 feet in the epidemic of 1855-56. He devotes pages to citations of various instances of contagion in which the intermediation of mosquitoes seems impossible or superfluous. Most of them are taken from the reports at the Geneva Congress of 1882, or the publications of the French authority on tropical diseases, Berenger Feraud. He states that the mosquito bites which are assumed to have been the means of infecting Dr. Carroll, lose their significance when we read that he was all the time attending patients in the Las Animas hospital, "where yellow fever patients were admitted in large numbers." Also that he had been occupied three days before in the dissecting-room where Agramonte had dissected a yellow-fever cadaver a few days previously, and which was very dirty. It seems very natural that he should have contracted yellow fever under these circumstances. Sanarelli himself had a light attack of yellow fever during his first researches at Rio, although he spent his nights in a remote, healthy suburb. It did not require much effort of the imagination, he observes, to attribute the infection to hospital contagion. He also criticises the case of the young soldier who showed symptoms of yellow fever after having been bitten by mosquitoes known to have sucked the blood of yellow-fever patients. He points out that the fact is stated in the report that the young man had made a surreptitious visit to the seashore fourteen days previously without leave, and he might have afterwards stolen away for a brief trip to some infected point without the knowledge of his superiors. Sanarelli does not deny that the mosquito may be casually the bearer of infection, as flies and other insects may accidentally transmit any infectious disease. Lazear was bitten by a mosquito while he was visiting a yellow-fever patient and drawing blood from him. It was assumed that the mosquito must previously have sucked the patient's blood, as Lazear developed the fever and died in consequence. Sanarelli exclaims, "Was it worth while to make such a fuss and call the attention of the world to a theory which the most superficial investigation shows to have no serious foundation, but which leads its authors to proclaim absurd deductions, such as the uselessness of disinfection in the prophylaxis of a disease that from remotest times has always shown itself one of the most highly contagious in human pathology!"

Queries and Minor Notes.

STATES NOT REQUIRING EXAMINATION.

St. Louis, Sept. 18, 1901.

To the Editor:—Please let me know where a graduate in medicine could practice without passing the State Board examination.

M. S.

Ans.—The laws of the following states admit graduates to practice medicine without examination, under varying conditions: Arkansas, Colorado, Kentucky, Michigan, Nevada, Nebraska, Oklahoma, Rhode Island, South Dakota and Wyoming. In some of the states only diplomas from certain schools are recognized; thus in Michigan the diplomas of some forty or fifty schools only are accepted and in Rhode Island similar scrutiny is exercised. In nearly all, more or less discrimination is made in regard to certain schools, but in these states more particularly than others.

SCOPOLAMIN-MORPHIN ANESTHESIA.

Corsicana, Texas, Sept. 14, 1901.

To the Editor:—In the issue of Aug. 17, 1901, on page 480, in article "Scopolamin-Morphin Anesthesia," the amount of scopolamin used is first given as .4 mg.; the second time as 4 mg. Kindly advise me which is correct, and is the article obtainable in English?

L. H. R.

Ans.—The former is correct. Instead of being .4 mg., it is given in the original 0004 of a gram. The total dosage advised by *Korff in the article in his proposed anesthesia is 12 decimilligrams*, or .0012 of a gram, in three doses of 4 decimilligrams each. The mistake is obvious and we think that no one will be misled by it. So far as we know there is no English translation of the article.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

A Handbook of Pathological Anatomy and Histology, with an Introductory Section on Postmortem Examinations and the Methods of Preserving and Examining Diseased Tissues. By *Francis* Delafield, M.D., LL.D., Professor of the Practice of Medicine, College of Physicians and Surgeons, Columbia University, New York, and T. Mitchell Prudden, M.D., LL.D., Professor of Pathology and Director of the Department of Pathology, College of Physicians and Surgeons, Columbia University, New York. Sixth Edition with 13 Full-page Plates and 453 Illustrations in the Text in Black and Colors. Cloth. Pp. 819. Price, $5.00. New York: Wm. Wood & Co. 1901.

The Office Treatment of Rectal Diseases Explained and Simplified. Being an Exposition of the Treatment of All Those Diseases, Both Medical and Surgical, of the Rectum, Anus and Sigmoid Flexure, the Cure of Which May be Accomplished Without Surgical Anesthesia. Illustrated. By Rufus D. Mason, M.D., Omaha, Neb., Professor of Rectal and Pelvic Surgery in the John A. Creighton Medical College. Cloth. Pp. 83. Price, $1.50. Omaha: F. B. Festner. 1901.

The Microscope and Its Revelations. By the late William B. Carpenter, C.B., M.D., LL.D., F.R.S. Eighth Edition, in which the first seven and the twenty-third chapters have been entirely rewritten, and the text throughout reconstructed, enlarged, and revised by the Rev. W. H. Dallinger, D. Sc., D.C.L., LL.D., F.R.S., etc. With 22 Plates and nearly Nine Hundred Wood Engravings. Cloth. Pp. 1181. Price, $8.00. Philadelphia: P. Blakiston's Son & Co. 1901.

The Health Resorts of Europe. A Medical Guide to the Mineral Springs, Climatic, Mountain and Seaside Health Resorts; Milk, Whey, Grape, Earth, Mud, Sand and Air Cures of Europe. By Thomas Linn, M.D., Doctor of Medicine, Faculty of Paris. Cloth. Pp. 281. Price, 2 s. 6 d. net. London: Henry Kimpton, Hirschfeld Bros. 1901.

Schoolboy's Special Immorality: Addressed Especially to Those Who Have the Charge of Boys. By Maurice C. Hime, M.A., LL.D., Sometime Head-Master of Foyle College, Derry. Third Edition, Revised and Enlarged. Cloth. Pp. 115. Price, $0.35. Philadelphia: P. Blakiston's Son & Co. 1901.

Atlas of the Diseases of the Skin. By George D., Clinical Professor of Diseases of the Skin, and Surgeons, N. Y. Part 1. Paper. Phila- J. B. Lippincott Co. 1901.

T nual Report of the Secretary of the Sta of the State of Michigan for the Fiscal year 1899. Cloth. Pp. 241. Lansing, Mich.: Rob Co. 1900.

Transactions of the Indiana State Medical Society, 1901. Fifty-second Annual Session, held in South Bend, Ind., May 15, 16 and 17, 1901. Cloth. Pp. 646. Logansport, Ind.: Wilson, Humphreys & Co. 1901.

Biennial Report of the Board of Health of the State of West Virginia, and Report of Vital and Mortuary Statistics for the Years 1898-99. Paper. Pp. 183. Charleston, W. Va.: The Tribune Co. 1901.

Transactions of the Sixty-eighth Annual Session of the Medical Society of the State of Tennessee, Nashville, 1901. Cloth. Pp. 416. Nashville: Marshall & Brace Co. 1901.

Transactions of the Vermont State Medical Society, 1900. Published by the Society. D. C. Hawley, M.D., Secretary. Cloth. Pp. 195. Burlington: Free Press Association. 1901.

Proceedings of the New York Pathological Society for the Years 1899 and 1900. Cloth. Pp. 347. Printed for the Society. 1901.

The Public Service.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy, week ending Sept. 14, 1901:

Medical Inspector H. Wells, ordered to the Boston Navy Yard, September 14.

Medical Inspector W. E. Taylor, retired, ordered to the Honolulu Naval Station.

Medical Inspector R. C. Persons, ordered to duty at the marine recruiting rendezvous, New York City, September 9, and to other special duty.

Surgeon M. H. Crawford, detached from duty at the marine recruiting rendezvous, New York City, September 9, and ordered to duty in connection with fitting out the *Illinois*, and to duty on that vessel when put in commission.

P. A. Surgeon D. N. Carpenter, detached from the naval hospital, Norfolk, Va., and ordered to duty in connection with fitting out the *Illinois*, and to duty on that vessel when put into commission.

P. A. Surgeon G. D. Costigan, resignation accepted, to take effect September 16.

Pharmacist J. Cowan, detached from the naval hospital, Mare Island, Cal., ordered home and granted sick leave for one month.

P. A. Surgeon C. E. Riggs, detached from the New York Navy Yard and ordered to the Port Royal Naval Station.

Asst.-Surgeon J. C. Thompson, detached from the Port Royal Naval Station and ordered to the *Columbia*.

Asst.-Surgeon R. M. Young, detached from the naval hospital, New York, September 14, and ordered to the New York Navy Yard, same day.

Asst.-Surgeon A. G. Grunwell, detached from the *Brooklyn* and ordered home.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine-Hospital Service, *during the week ended Sept. 14, 1901:*

SMALLPOX—UNITED STATES.

California: San Francisco, Aug. 25-Sept. 1, 2 cases.

Massachusetts: Aug. 31-Sept. 7, Boston, 13 cases; Medford, 1 case.

Minnesota: Minneapolis, Aug. 31-Sept. 7, 2 cases.

New Jersey: Newark, Aug. 31-Sept. 7, 9 cases, 2 deaths.

New York: New York, Aug. 31-Sept. 7, 6 cases, 4 deaths.

Pennsylvania: Philadelphia, Aug. 31-Sept. 7, 12 cases, 4 deaths.

Utah: Salt Lake City, Aug. 24-Sept. 7, 5 cases.

Wisconsin: Green Bay, Sept. 1-8, 1 case; Milwaukee, Aug. 31-Sept. 7, 1 case.

SMALLPOX—FOREIGN.

Belgium: Antwerp, Aug. 17-24, 1 case.

Brazil: Pernambuco, July 17-31, 44 deaths.

British Columbia: Vancouver, Aug. 1-31, 1 suspect.

Colombia: Panama, Aug. 26-Sept. 2, 12 cases.

Ecuador: Guayaquil: June 22-Aug. 7, 1 death.

France: Paris, Aug. 17-24, 9 deaths.

Great Britain: Leeds, Aug. 24-31, 1 case: London, Aug. 17-24, 41 cases.

India: Calcutta, Aug. 3-10, 2 deaths; Madras, Aug. 3-9, 7 deaths.

Italy: Messina, Aug. 16-24, 8 cases; Naples, Aug. 17-24, 115 cases, 22 deaths; Palermo, Aug. 19-24, 1 death.

Russia: Moscow, Aug. 10-17, 2 cases; St. Petersburg, Aug. 4-11, 12 cases.

Uruguay: Montevideo, July 18-25, 10 cases.

YELLOW FEVER.

Costa Rica: Liberia, Aug. 25, prevalent; Port Limon, Aug. 18-24, 8 cases, 1 death.

Cuba: Havana, Aug. 24-31, 7 cases, 2 deaths; Inoculation Station, Aug. 24-31, 1 case.

Mexico: Merida, Aug. 16-24, 2 deaths; Vera Cruz, Aug. 24-31, 3 cases, 2 deaths.

CHOLERA.

India: Bombay, Aug. 6-13, 9 deaths; Calcutta, Aug. 3-10, 6 deaths; Madras, Aug. 3-9, 45 deaths.

Japan: Island of Shikohu, Aug. 6, 3 cases; Yokohama, Aug. 3-10, 1 case.

PLAGUE—INSULAR.

Philippines: Camp Stotzenberg, July 13-20, 2 cases; Manila, July 13-Aug. 3, 26 cases, 21 deaths.

PLAGUE—FOREIGN.

India: Bombay, Aug. 6-13, 197 deaths: Calcutta, Aug. 3-10, 17 deaths; Karachi, July 24-Aug. 1, 17 cases, 13 deaths.

Japan: Formosa, Aug. 6, epidemic.

Straits Settlements: Singapore, July 20-27, 1 death.

China: Hongkong, July 27-Aug. 3, 13 cases, 11 deaths.

THE ETIOLOGY AND CLASSIFICATION OF CIRRHOSES OF THE LIVER.*

VICTOR C. VAUGHAN, M.D., LL.D.
ANN ARBOR, MICH.

The term cirrhosis was first applied to a pathologic condition of the liver, in 1819, by Laennec, who was led to select this name on account of the color of the liver—reddish-yellow or tawny. This term is an unfortunate one, inasmuch as the color of the liver in this disease varies with the relative amounts of fatty matter and biliary pigment in the tissue, and furthermore, it gives no indication of either the etiology or the pathology of the disease. Before Laennec, Fernel had written concerning the action of wine in causing scirrhus—induration—of the liver; Vesale had also discussed atrophy of the liver observed in alcoholics; Morgagni had spoken of ascites due to compression or occlusion of the intra-hepatic branches of the portal vein, and Baillie, in 1803, had recognized the relationship between dropsy and atrophy of the liver. However, credit should be given to the great teacher, Laennec, for bringing prominently to the attention of the profession one form of the diseases of the liver which is still designated by the name that he coined. The term sclerosis is also objectionable, because, while the hardening due to a cicatricial contraction may occur in the later stages, it is not a primary and essential feature of the pathologic process. Generally, members of the profession now understand by the term cirrhosis an abnormal proliferation of the connective tissue of the liver. The designation, interstitial hepatitis, is more suitable than either of the names already mentioned, but even this is not free from objection, because it is more than probable that in one form of the disease, or, more properly speaking, in one of the diseases designated by the term cirrhosis, the degenerative changes begin in the parenchyma of the organ and the involvement of the connective tissue is a secondary process. At first it was believed that the liver is always enlarged in the early stages and that the marked atrophy observed at autopsy is due to cicatricial contraction of the overgrowth of connective tissue.

In 1846, Requin called attention to the fact that hypertrophy of the liver is not always followed by atrophy, and three years later one of his students, Mesnet, reported a case of cirrhosis with extensive hypertrophy and reached the following conclusion: "Cirrhosis is not necessarily followed by atrophy. The two diseases, hypertrophy of the liver and cirrhosis can exist in the same individual. I can not agree with Cruveilhier, who holds that cirrhosis always consists of atrophy of the majority of the liver granulations and leads to diminution in the size of the organ, because at least two cases of cirrhosis with hypertrophy have been observed."[1]

In 1857, Todd, in a clinical lecture, contrasted the atrophic and hypertrophic forms of cirrhosis and stated: "The disease (atrophy), which no doubt is most frequently the result of intemperate habits in drinking, is very common, and all the cases resemble each other to a remarkable extent. It can not be discerned with certainty in its early stages, although no doubt a practiced eye would seldom be wrong, for the chronic changes which terminate in this shrunken and contracted state of the organ are, as I have already stated, most stealthy and insidious in their approach. A similar group of symptoms accompanies an enlarged and sometimes very much enlarged, condition of the liver, and systematic authors, especially those of late years, regard these two conditions as one and the same disease—cirrhosis. Indeed, they lay it down that the enlarged liver is an early stage of the contracted liver, and that the former by the gradual diminution of its size passes into the latter. I find it impossible to accede to this view, and I am anxious to call your special attention to the two cases that you may, as opportunities offer, direct your attention to their clinical phenomena, and watch whether the one can be traced into the other."

In 1871, Ollivier reported a case of hypertrophic cirrhosis, but it was the thesis of Hanot, in 1876, with the subsequent investigation of the same author and of others stimulated by his work, that has led to the recognition of hypertrophic cirrhosis as a distinct disease, and, for this reason, this form of cirrhosis is often designated as the cirrhosis of Hanot, in contradistinction to that of Laennec—the atrophic form. Fortunately another great French clinical teacher, Charcot, took up the subject and gave great impetus to the study. Charcot divided cirrhoses of the liver into the following:

1. An insular, monolobular, intralobular and interlobular form of biliary origin—the cirrhosis of Hanot.
2. An annular, multilobular, perilobular form of venous origin—the cirrhosis of Laennec.
3. A rare monocellular form observed in congenital syphilis.

Experimental research, clinical observation and the study of the pathologic conditions have confirmed the views of Todd, Hanot and others just mentioned, and we no longer recognize hypertrophic and atrophic cirrhoses as different stages of the same disease, but as distinct conditions, unlike in origin, in etiology, in symptomatology and in pathology. I will, therefore, proceed to discuss these separately, then compare and contrast them, and finally will speak of the mixed forms which are not infrequently seen.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee of the Section: Drs. Frank Billings, George Dock and J. M. Anders.

[1] Similar cases were reported by Monnert (1852) and Gubler (1857), but I have not seen these reports.

ATROPHIC CIRRHOSIS.

Gross Appearance.—The liver is reduced both in size and weight. It varies in color and may be brownish, reddish-brown, reddish-yellow, gray or grayish-brown. The surface is covered with nodules which vary in size from those barely discernible to those as large as a filbert. The border of the liver is thickened, blunt and indented by fibrinous bands. On removing the strongly adherent capsule, the nodules stand out more prominently, and the appropriateness of the term, "hob-nailed liver," becomes evident. On section, the organ is found to be more or less hardened and the cut surface shows nodules of varying size surrounded by connective tissue.

Etiology.—As has been stated, the influence of the abuse of alcoholic drinks in the causation of this condition has long been recognized, and among the etiologic factors alcohol holds the first place. The more concentrated the alcoholic beverage, the more marked is the effect; consequently, brandy and whisky drinkers are more likely to develop this disease than are those who confine themselves to fermented and malted drinks. For like reason, those who take these alcoholic drinks on an empty stomach are in greater danger than are those who limit their potations to their meals. It has been stated that the more fusel oil there is in the beverage the more injurious is it in its effects on the liver. All alcoholics do not develop cirrhosis, and it is believed that a sedentary life contributes to the ill effects of the poison. De Giovanni thinks that a scrofulous taint favors the development of cirrhosis and that there is a congenital predisposition to this disease. However, this opinion is altogether theoretical and has, as yet, no scientific basis.

The positive evidence from clinical observation that alcohol is the most common cause of atrophic cirrhosis in man, has led many investigators to attempt to induce this condition in the lower animals by the use of this agent. It would require too much space and time to even enumerate all the investigations that have been made with this object in view. Most of these studies, some of which have been made in the most careful and painstaking manner, have given apparently only negative results, and it can be said that no one has succeeded in inducing well-marked interstitial hepatitis in the lower animals by administering alcohol to them. Notwithstanding this fact, these studies have been of much value in the extension of our knowledge of the etiology and pathology of atrophic cirrhosis, and it will be of service to us to briefly state here the effects produced in the liver by the experimental employment of alcohol.

The findings of Afanassijew may be summarized as follows: In dogs the continued administration of alcohol, either with or without amylic spirit, causes a degeneration of the hepatic cells, which swell, become more rounded and are easily detached from the stroma. The nuclei of many of these cells contract and fail to react normally to stains. In rabbits these changes are more marked and sometimes whitish maculæ may be seen macroscopically. These spots contain in their centers branches of the portal vein and sometimes continue along the peripheral parts of the lobules. The hepatic cells in the region of these maculæ show a more or less marked condition of coagulation necrosis. The cells near the center of the maculæ are more markedly affected, while in those at the periphery the destructive changes are less evident. In addition to the parenchymatous and fatty degeneration in chronic alcoholic poisoning there is observed a tendency to lymph stasis. This is especially observable in the liver, brain, stomach and intestines. Whether this is due to the retarded circulation from weakened heart action or to effects on the central nervous system can not be determined. The degenerative changes in the liver are in direct proportion to the severity of the intoxication. The addition of amylic alcohol intensifies, but does not alter, the character of the destructive changes.

The same investigator injected diluted alcohol directly into the portal circulation. The animals thu treated survived the operation and were killed from seven hours to eight days afterward; one dog was not killed until four months after the injection. The action on the tissues of the liver was found to be more pronounced when the alcohol was administered in this way The liver cells along the branches of the portal vein showed the following changes: The nuclei were shrunken and individual chromatin granules could not be recognized. The cell protoplasm appeared cloudy and finely granular. The cells themselves were contracted; the hepatic capillaries were dilated and filled with blood. These changes were not uniform throughout the lobules, but were distributed in patches, resembling the parenchymatous fatty degeneration observed as a result of the indirect action of alcohol. Similar appearances have been seen after long-continued administration by the mouth. With larger doses—from 2.5 to 5 c.c. of 48 per cent. alcohol—injected into the portal circulation, necrotic changes were obtained. Macroscopically the necrosis was observed as whitish spots of varying size on the surface of the liver. The necrotic cells were found to be surrounded by a zone of cells showing fatty degeneration and beyond these were seen normal cells. When the animal lived three or four days after the operation, the connective tissue cells of the stroma were found to be increased in number and numerous giant cells were observed. After a time true cicatricial tissue replaced the necrotic areas.

Afanassijew concludes his observations as follows: We have obtained by the injection of alcohol into the liver, also by continued administration by the mouth in rabbits, necrotic areas in the liver similar to those induced by phosphorous and arsenic. These necrotic areas stimulate the surrounding normal tissue and this stimulation leads to proliferation of the cells of the stroma and the development of giant cells. In short, this investigator believes that alcoholic cirrhosis begins by inducing changes in the liver cells, leads to fatty degeneration and necrosis, and that the proliferation of the connective tissue is subsequent to and consequent upon the changes in the hepatic cells.

Ackermann concludes his researches upon this subject with the following statement: "The proliferation of the connective tissue is not a result of the direct action of alcohol, but is due to the stimulating effect of the liver cells, altered by the action of the poison, on the connective tissue."

Practically all who have studied experimentally the action of alcohol on the liver of animals, have concluded that this poison causes granular and fatty degeneration in the liver cells. Some have reported slight proliferation of connective tissue, and the most reasonable conclusion is that which makes the connective tissue changes subsequent to and dependent upon alterations in the hepatic cells. When we remember that men often abuse alcohol for years before they develop a typical atrophy of the liver, we need not be surprised when we fail to induce a like condition in animals even after the administration of this poison for months, and it seems to me that with the clinical and experimental evidence before us, we are justified in coming to the conclusion that in alcoholic cirrhosis the pathologic changes begin in the hepatic cells.

Chronic phosphorous poisoning also has been long recognized clinically as a cause of atrophic cirrhosis, and a typical form of this disease, with ascites, has been developed experimentally in animals by the administration of this agent. In these experiments it has also been shown beyond doubt that the pathologic changes begin in the hepatic cells and that the proliferation of connective tissue is secondary. Aufrecht, after experimenting with phosphorus, reaches the following conclusion: "The parenchymatous inflammation is the primary process; in those cases in which the harmful agent acts long enough or powerfully enough to prevent speedy disappearance of the parenchymatous inflammation, secondary changes in the interstitial tissue develop as a consequence of the diseased condition of the parenchymatous parts."

Clinicians have frequently observed atrophic cirrhosis in cases of chronic poisoning with certain metallic compounds, and the experimental study of the effects of these agents on the lower animals has contributed valuable additions to our knowledge of the histogenesis of this disease.

The researches of Ziegler and Oblonsky, so far as they pertain to the action of arsenic on the liver, may be condensed into the following brief statements: Fatty change in the hepatic cells is always apparent and evidently is one of the early effects of chronic arsenical poisoning; indeed, in acute poisoning, when the animal dies in a few hours after the administration of a single dose, some of the hepatic cells can be seen on microscopical examination to be filled with minute droplets of fat. In some instances the degenerative changes in the hepatic cells are quite as marked as they are in the milder forms of phosphorus poisoning. In many animals fatty change in hepatic cells is the only change detectable. That some of the cells involved are still capable of multiplication is shown by the observation of typical karyokinetic figures. As a secondary stage in the progressive effects of arsenic, there appear necrotic areas; then, the periportal connective tissue is often found to be in a state of proliferation, which is indicated partially by the presence of more or less abundant karyokinetic figures and partially by the increase of cellular elements, and by the presence of numerous large cells with large nuclei and rich in protoplasm. It will be seen that in the order of development these changes correspond with those observed after alcohol and phosphorus poisoning. In some cases of chronic arsenic poisoning the fatty changes in the liver are more extensive than they are even after death from phosphorus, and when death is delayed for two or three weeks the hepatic cells show marked atrophic changes.

While chronic poisoning with the soluble compounds of aluminum is not known to occur in man, the researches of Siem and Dölken on animals show that these salts have much the same effect upon the hepatic cells of animals as those observed after poisoning with other metallic compounds. The liver is dark-red and the surface may be marked with prominent yellow blotches. The substance of the organ is somewhat friable and microscopic examination shows the hepatic cells undergoing granular and fatty degeneration.

Among the etiologic factors of atrophic cirrhosis, chronic lead poisoning has long been recognized, and Lafitte has induced a typical cirrhosis of the liver in rabbits by the long-continued administration of soluble salts of this metal. This author suggests that the presence of small quantities of lead in wine may be partially responsible for the cirrhosis observed in drinkers of this beverage. Atrophic cirrhosis is also likely to occur among smelters of copper, even when these men have been total abstainers from the use of alcohol. The effects of lead and copper on the tissues of the liver are practically the same as those of the other poisonous salts and of phosphorus and alcohol.

It seems to me that it must be admitted, from the evidence already presented, that in the development of atrophic cirrhosis the primary changes occur in the parenchyma of the liver and that the involvement of the connective tissue and the proliferation of the same is secondary to and consequent upon the necrotic changes in the hepatic cells.

There are believed to be other etiologic factors possibly concerned in the development of atrophic cirrhosis. Frerichs gave syphilis a prominent place in this list, and Thierfelder thinks that syphilitic cirrhosis differs from that induced by alcohol in the more uneven distribution of the pathologic changes in the hepatic tissue. However, since syphilitics are so frequently given to alcoholic excesses, some caution is necessary in reaching conclusions on this point. Cirrhosis sometimes accompanies amyloid disease and it is possible that both may be due to the same cause, especially to syphilis. Many English clinicians with large experience in India believe that the use of irritating spices and other condiments contributes to the production of cirrhosis of the liver so frequently observed in that country. The toxins of some of the acute infectious diseases, such as cholera, typhoid fever and the plague, are believed to be capable of inciting changes in the liver leading to atrophic cirrhosis. Semmola says, "Infective processes play a great part in the causation of cirrhosis." The same author assigns a prominent place to malaria among the causative agents of this pathologic state. It is quite the fashion at present to attribute most of the ills of life to autointoxication, and this much-abused and frequently misapplied term is found in many of the lists of the etiologic factors of cirrhosis. It is frequently said that it is not alcohol that causes cirrhosis of the liver, but that the drink so alters the digestive tract and its secretions that the products of an abnormal and imperfect digestion acting on the liver cause the histologic changes that result in this disease. Even were this a demonstrated fact, which it is not, the disease should not be termed one of the autointoxications, but should be said to result indirectly from the abuse of alcohol. In either case alcohol is the causative agent, whether it acts directly on the hepatic cells, or indirectly by altering the chemism of digestion. In either case the alcohol is the toxic agent and since it is introduced from without and is not generated within the body, it is not an autotoxin. As we have seen, alcohol, phosphorus and the metallic poisons, possibly also syphilis, malaria and other infectious diseases, are the most common factors in the causation of atrophic cirrhosis, and none of these are autotoxins.

Pathology.—Is the liver in the early stages of this form of cirrhosis enlarged? This question has met with conflicting answers. Laennec believed that hypertrophy always precedes atrophy and this view is probably the one most generally held to-day. On the other hand, Todd taught that when uncomplicated with other diseases, the liver in this form of cirrhosis is never larger than normal, and that from the first it begins to decrease in size. Rosenstein says: "Es giebt eine genuine Schrumpfleber, das ist die atrophische Form. Kein Stadium der Vergrösserung geht hier voraus." However, it is difficult to answer those who believe in primary hypertrophy. They say that hospital cases are not seen until contraction of the proliferated connective tissue begins and circulation in the branches of the portal vein is more or less interrupted, and they admit that even in private practice this disease can not be diagnosed with any certainty until atrophy begins, and yet they contend that there is hypertrophy primarily. It will be seen that an argument of this kind can not easily be refuted. However, we may safely say that there is no marked hypertrophy; if there be any, atrophy comes soon, and, as has been stated above, before a positive diagnosis can be made. We have seen in experimental atrophic cirrhosis that destructive changes begin in the parenchyma before any proliferation of the connective tissue and that there is no stage of hypertrophy. There is probably no absolute, mathematical relation between the rates at which destruction of hepatic cells and proliferation and contraction of connective tissue take place; however, as the latter results from the former, it is safe to assume that the effect is in proportion to the cause.

The character and localization of the proliferation of connective tissue are interesting questions in the study of this disease. Charcot designates the disease as annular, because the larger bands of connective tissue encircle the parenchyma and smaller bands divide these areas into segments. He also characterized it as multilobular, because the encircled areas embrace many acini. Charcot believed that the disease is essentially a phlebitis or a periphlebitis of the intra-hepatic branches of the portal vein—a view which has been disproved by more exact observations.

Aufrecht holds that there is in reality no true proliferation of connective tissue and this view seems to be in all probability the correct one. His statements on this point are so important that I shall take the liberty of condensing them into the following: In order to explain the pathogenesis of this disease it is desirable to mention the fact that simultaneously with the extension of the interacinous tissue, there is invariably contraction of the acini. The one does not occur without the other. The degeneration of the hepatic cells, which is the primary phenomenon in the development of the disease, begins always in the periphery of the acini and extends towards the center, and the altered hepatic cells themselves constitute the greater portion of the interacinous tissue. If sections of a liver in this disease be prepared with the Biondi-Heidenhain triple stain the cells in the periphery of the contracted acini will be found reduced in size. Reduction in size is not the only change observable in these cells. They have become spindle-shaped and their nuclei have undergone an analogous alteration in form. The latter are stained blue, while the protoplasm has a reddish appearance. In many cells, the nuclei are no longer detected and the reddish cells can be seen matted together in the interacinous tissue. This author concludes from these findings that the increase in the interacinous tissue is not due to the proliferation of the connective tissue elements, but to its augmentation by the altered hepatic cells. He says furthermore: We have to do here with a process similar to that by which the cells of the rete Malpighii of the skin are converted into the scales of the epidermis. "In atrophic cirrhosis the contraction is not due to proliferation of connective tissue, but to the shrinkage of *acini and groups of acini.* The small, non-nucleated spindles, into which the peripheral hepatic cells are converted, occupy much less space than the normal cells." He adds: This picture is not infrequently clouded by the marked fatty degeneration of the remaining cells of the reduced acini or by an acute atrophy of the same. The first is relatively frequent, then there appears to be a sharp line of demarcation between the remaining hepatic cells and the interacinous tissue, when unstained sections, or those colored with other reagents than that above mentioned are examined. In these cases the transitional forms are not recognized. Acute atrophy of the remaining hepatic cells is relatively infrequent, but that it does occasionally occur may be recognized clinically, by the terminal icterus accompanied by marked ascites and prolonged coma, and microscopically, by the total disappearance of hepatic cells of normal shape. The so-called newly-formed biliary capillaries are observed very rarely in atrophic cirrhosis, but Charcot is in error, as Ackermann has pointed out, when he states that the absence of these is pathognomonic of this disease, and their actual appearance excludes the possibility of a true cicatricial process in this disease.

It will be seen from the statements already made, and the evidence might be multiplied several times, that recent investigations have established the essential identity of the changes observed in the cirrhotic atrophy of the liver seen at autopsy and the changes induced in animals experimentally by alcohol, phosphorus and the metallic poisons. The differences are those of degree and not of kind, and when we take into consideration the length of time that is required to induce this disease in alcoholics, the differences in degree are easily understood.

Symptomatology.—This disease advances at first insidiously and generally manifests itself by ascites, which is an early and constant condition. Subjective symptoms may be wholly wanting, and in any case are by no means characteristic. The ascites is due to obstruction to the flow of blood in one or more of the intrahepatic branches of the portal vein. When the umbilical vein is not completely obliterated, and Baumgarten has shown that it frequently remains partially open, a collateral circulation may be established, and this leads to the appearance about the navel of what is known as the *caput Medusæ;* or anastomoses may be opened up between the portal vein and the inferior vena cava.[2]

In discussing the methods by which Nature attempts to establish a collateral circulation, Bamber says, "This is accomplished through the communication of the internal hemorrhoidal with the hemorrhoidal branches of the hypogastric vein, or by anastomoses between the vessels of Glisson's capsule and the diaphragmatic vein, also through the superior gastric and the esophageal, and through this with the azygos." Edema of the lower extremities may appear, but seldom does so until late in the course of the disease.

---

[2] It might be noted that in very rare instances the inferior vena cava has been found to be strangulated by bands of connective tissue in the liver.

The spleen is generally enlarged. Whether this is due wholly to obstructed flow of blood through the liver or to coincident disease of the spleen can not always be determined.

Structural disease of the kidney is not a frequent accompaniment of atrophic cirrhosis, although albumin and casts may appear in the urine, and Semmola has reported the presence of peptone. In cases in which the ascitic accumulation is great the volume of urine is diminished, but according to Aufrecht this condition is attributable to weakened action of the heart. Semmola very properly, it seems to me, emphasized the desirability of making frequent quantitative determinations of the amount of urea, which is eliminated in reduced amount on account of the destructive changes in the hepatic cells, since these are concerned in its formation. However, such determinations are of no value unless strict account is kept at the same time of the amount of nitrogenous food ingested. With the decrease in the amount of urea eliminated in the urine there should be a corresponding increase in the amount of ammonia, and this condition has been reported by Halevoorden and Stadelmann, but I know of no exact scientific research on this point. It is believed by physiologists that one of the antecedents of urea is the carbamate of ammonia which normally is converted in the liver into urea; consequently, when a large proportion of the heptatic cells is diseased the amount of urea eliminated should be decreased and that of ammonia correspondingly increased.

There is generally a catarrhal condition of the digestive tract. Indeed, in most cases of atrophic cirrhosis, this disturbance of the stomach and intestines precedes the development of the changes in the liver, and is due to the same cause, i. e., alcohol. Hematemesis is not unusual, especially in alcoholic cirrhosis. The causes of frequent hemorrhages from the stomach may be stated as follows: 1, as has been stated, the digestive organs are already diseased from the local action of the alcohol; and 2, interruption of the flow of blood through the portal vein leads to distension of the gastro-intestinal radicles of this system. Not infrequently the hemorrhage is esophageal. and this is explained by the dilatation of the veins of the esophagus, through Nature's attempt to establish collateral circulation after the manner already mentioned.

Icterus is an unusual manifestation of this disease in uncomplicated form. The hepatic cells being diseased, it is probable that there is diminished formation of bile pigment, and the gall ducts being usually unaffected, there is free escape *per vias naturales* for all that is formed. During the later stages of the disease jaundice may appear and possibly be quite marked. This is supposed by some clinicians to indicate acute atrophy and it is often accompanied by coma.

HYPERTROPHIC CIRRHOSIS.

Gross Appearance.—The liver is always enlarged and may be enormously so, weighing in some rare instances as much as nine or ten pounds. The surface is finely granular and brownish or reddish in color. Adhesions to adjacent organs are frequently seen. In consistency the tissue of the liver is firm and may be very hard. Freshly cut surfaces are granular and of varying color, depending upon the proportion of bile pigment staining the organ.

Etiology.—There has been practically no scientific investigation into the causative agents concerned in the production of this disease; however, most clinicians now agree that it is of infectious origin, which view was, so far as I know, first suggested by Senator. I know of no thorough bacteriologic study of this condition; but the colon and typhoid bacilli are regarded as the most frequent infections, although a coccus, not yet well studied, has been found in some instances. Frequently both the bile and the liver tissue have been reported sterile, but since Adami has shown that it often requires many days for the development of germs actually existing in tissues, such evidence is not of value. Moreover, the bile may be actually sterile at a time when the tissue surrounding the ducts is undergoing most destructive changes through the agency of bacteria. The possible avenues of infection are from the intestines, through the gall passages and through the blood and lymph. The probabilities are that infection generally, if not invariably, comes from the intestines and is due to the extension of catarrhal conditions or to the passages of specific organism up the biliary tract. The frequency with which the typhoid bacillus finds its way into the gall bladder and its persistent growth in this viscus, has been attested by more than one observer.

Clinicians agree that alcohol is not a direct causative agent in this disease. Certainly hypertrophic cirrhosis may be developed in alcoholics, but quite as frequently it appears among those who have not abused this beverage. Indirectly, by causing irritation of the mucous membranes of the stomach and intestines and by converting this tissue into suitable culture beds for the growth of bacteria, alcohol may sometimes be a factor in the causation of this disease, just as it may play a similar rôle in the development of many other infectious diseases.

There is no sufficient reason for believing that any chemical poison, except bacterial toxins, are concerned in the causation of this form of cirrhosis. With our present knowledge it must be attributed in all cases to infection. While, as has been stated, the experimental proof of the bacterial origin of hypertrophic cirrhosis is largely wanting, the conclusion that it is due to infection is so well founded that much contrary evidence of the most positive character would be required to cast doubt upon this view. The evidence on this point may be briefly summarized as follows: 1. It frequently begins like an ordinary catarrhal jaundice, which seemingly becomes chronic. 2. It is often, if not invariably, accompanied by cholecystitis. 3. It is essentially a febrile disease with periods of remission and exacerbation. 4. It is accompanied by enlargement of the spleen and many of the lymphatics, as is the case in some of the infectious diseases. and, moreover, the enlargement of the spleen is not that due to obstructed blood flow, as is the case in atrophic cirrhosis, but appears to be similar to, if not identical with, that observed in other infectious diseases. 5. The primary changes occur in the epithelium of the gall ducts, where they would naturally be found by extension of the disease process from the intestines up through the biliary tract.

Pathology.—While there have been some differences of statement among those who have studied microscopically the changes in the liver in this disease, there seems now to be reasonable agreement on the essential points, which may be condensed as follows: 1. There are no destructive changes in the hepatic cells. According to Hanot, the integrity of the parenchyma is an absolute characteristic of hypertrophic cirrhosis. Some observers find no destructive changes in the hepatic cells, but do find evidence of unusual growth in this tissue. Ziegler says, "The size of many of the nuclei and their richness in chromatin, together with the size of the cells themselves, make it probable that in this disease there is proliferation of the hepatic cells and that the colossal size reached by the liver is not solely due to the proliferation of the connective tissue." Heineke states: "In the cirrhosis of Hanot the hepatic cells remain intact, neither shrunken nor fatty; the nuclei are normal and stain well; indeed, actual proliferation of these cells may be observed." Aufrecht makes the following statement: "It is an evident characteristic of hypertrophic cirrhosis that all the hepatic cells are enlarged, and contain a larger number of nuclei than under normal conditions. In these changes lies the criterion of hypertrophic cirrhosis." While all agree that the primary changes do not occur in the hepatic cells, there are those who think that destructive changes may result secondarily in the parenchyma. This opinion is held by Heineke, who states, "Primary degeneration of hepatic cells is with certainty excluded in Hanot's cirrhosis; indeed, the first proliferation processes do not occur in the vicinity of the lobules, but in Glisson's capsule and in the region of the larger gall ducts. The hepatic cells in most cases remain unaltered, and it is so constantly the case that Hanot and Schachmann insist that integrity of the parenchyma is an essential condition in hypertrophic cirrhosis with icterus. However, because primary degeneration of the hepatic cells does not occur is no guarantee that these cells always escape secondary effects. Conditions influencing the parenchyma may co-exist with those resulting in hypertrophy, and, indeed, may affect the part most highly involved in the hypertrophic process, but when the parenchyma does undergo destructive changes atrophy, or at least a decrease of the hypertrophy, must result." If I understand Heineke aright, he believes that the two processes (that of hypertrophy of the connective tissue and that of atrophy of the parenchyma may co-exist in the same liver; this amounts to mixed cirrhosis, to which I shall return later.

2. The primary changes in the development of this disease occur in the epithelial cells of the gall ducts. On this point there is some diversity of statement; certain observers have reported most extensive and destructive changes in the epithelium, while others have found evidence of pericholangitis, with the epithelium of the ducts intact; but when we remember that this disease may continue from one to eight or ten years before it causes death and that during its course it shows marked exacerbations and remissions, it is no longer a matter of surprise that the condition of the epithelium in microscopic sections is by no means constant. Hanot generally, not invariably, has found characteristic lesions in the gall ducts, with proliferation and desquamation of the epithelium causing obliteration of the lumen. The fact that icterus is one of the earliest manifestations of this disease and that this symptom continues to the end *pari passu* with the exacerbations and remissions, is strong proof of the early and constant involvement of the epithelium of the ducts in the inflammatory changes, because the icterus is best explained by the occlusion of the ducts. On this point Hanot remarks, "The lesions of the bile ducts and their more or less extensive obliteration by the young proliferating cells, together with the chronic inflammation of the surrounding tissue, by obstructing the flow of the bile, must be considered as the causes of the icterus." Heineke, after quoting the above from Hanot, adds, "I have found similar destructive changes in the epithelium in most of my cases. Besides occlusion of the ducts by desquamation of the cells, another hindrance to the flow of bile may be found in the formation of deposits in this fluid and consequent thickening of the same by inflammatory processes. Actual compression of the ducts by contraction of the connective tissue may occur in the later stages of the disease." It is a fact established by observation and experiment that certain bacteria multiply in the bile of the gall bladder, causing the formation of deposits, and that gall-stones originate in this manner has been quite conclusively demonstrated by Naunyn.

3. The tissue about the branches of the portal vein largely escape involvement in this disease, or are affected only late in its course. This explains the infrequency of ascites in hypertrophic cirrhosis.

Symptomatology.—This disease most frequently appears in persons under 40 years of age. Enlargement of the liver and icterus are the first prominent symptoms. Ascites is rare and is not marked when present. The causes of the presence of icterus and the absence of ascites I have already discussed. The disease generally runs a chronic course, with periods of exacerbation and remission which are accompanied by a rise and fall of temperature. As the disease progresses anemia and emaciation are marked and disturbances of the digestive organs become more prominent. The spleen and many of the lymph glands are enlarged. The urine is stained with bile, and the feces are generally normal in color, but may be colorless. Toward the close the patient may pass into a typhoid condition with marked fever and delirium.

CONTRAST AND COMPARISON OF THE TWO DISEASES.

Atrophic cirrhosis is sometimes designated as the cirrhosis of Lænnec and the hypertrophic disease as the cirrhosis of Hanot. The former is known as atrophic cirrhosis because from its earliest possible recognition the liver is less than normal in size; while the hypertrophic is known as such because at every stage of the disease the liver is larger than normal.

The atrophic is known as venous cirrhosis because of the early and constant involvement of the intra-hepatic branches of the portal vein; the hypertrophic is known as biliary cirrhosis because of the early appearance and constancy of icterus. The former might be known as toxic, and the latter as infectious cirrhosis.

In the atrophic disease, ascites is an early manifestation and is often marked; in the hypertrophic, ascites is frequently absent and is never great. In the atrophic, icterus appears late, if at all; in the hypertrophic, icterus appears early and is constant.

Finally, in atrophic cirrhosis the primary destructive changes are in the hepatic cells; in hypertrophic cirrhosis the epithelium of the gall ducts is the site of the primary involvement.

MIXED CIRRHOSES.

From what has been said concerning the etiology and pathology of these diseases, it must be evident that their co-existence in the same individual may be seen. As has been stated, alcohol is the most frequent cause of atrophic cirrhosis and indirectly it may contribute to the causation of the hypertrophic disease. If all cases seen clinically were well-marked, typical forms of either disease, diagnosis would not be difficult, but unfortunately this does not always occur. There are many well-marked cases of each disease and there are others which confound alike the clinician and the pathologist; many of these are undoubtedly due to the coexistence of the two diseases in the same individual. An infection may follow or precede an intoxication.

ADDENDUM.

While it was not my intention to say anything concerning the treatment of either of these diseases, I must be pardoned for adding just a few words on this subject. In atrophic cirrhosis the first thing to do is to discontinue the cause of the trouble, which, as we have seen, is most frequently alcohol. I will say nothing concerning the treatment of symptoms, but I do want to state that the pathologist has abundantly shown that when the cause is removed hepatic cells, even though undergoing marked fatty degeneration, may recover themselves. In my opinion the only scientific treatment for atrophic cirrhosis that has been proposed is that of Semmola, who reduces the amount of food to a minimum and administers this in a form least likely to tax the hepatic cells. He confines his patients to the use of milk, or when this is impossible, to milk and eggs. Digestion may be aided by the administration of dilute hydrochloric acid, and the action of the stomach may be improved by giving bitter tonics. The bowels should be kept in good condition, and this is best accomplished in this disease by the use of mineral waters. The heart must be watched and the administration of digitalis is often indicated.

In the treatment of hypertrophic cirrhosis small doses of calomel administered according to the method of Nothnagel have probably given the best results. When there is obstruction of the common duct, or when there is stone in the gall-bladder, surgical operation is clearly indicated, and I am inclined to the opinion that the time will come when surgery will be relied upon in the treatment of all cases of hypertrophic cirrhosis, inasmuch as it is possible only by operation to reach and disinfect the biliary passages.

For the purpose of saving space, I have refrained from giving the literature on cirrhosis of the liver, and I will refer those interested in the subject to the 13th volume of the "Real-Encyclopädie der gesammten Heilkunde," in which will be found an article by Aufrecht, followed by a fairly complete list of references up to the time of writing—1897.

ON THE TREATMENT OF CIRRHOSIS OF THE LIVER.*

J. H. MUSSER, M.D.
PHILADELPHIA.

Cirrhosis of the liver—often called alcoholic cirrhosis—is seen under the following circumstances: 1, without symptoms, the patient having died from other causes; 2, without symptoms until a climax is reached in the sudden outbreak of gastric or intestinal hemorrhage, terminating the life of the patient; 3, with symptoms due to obstruction of the portal vessels; 4, with those due to catarrh and obstruction of the bile ducts; 5, with combined portal and duct symptoms; 6, in very rare instances, a certain ill-defined cachexia, symptoms of auto-intoxication and the physical signs of a contracted liver, may suggest in a patient of alcoholic habits the presence of this form of cirrhosis. We will defer the consideration of the symptomatic treatment until a later portion of the paper.

The morbid process in alcoholic cirrhosis is clearly defined and if the diagnosis of the first stage, so-called, could be positively determined indications for treatment to combat this process are manifest. Knowledge of such process would lead us at once to suggest control or removal of the cause; regulation of the duty to remove undue stress of work of the organ; proper clothing to prevent congestions of viscera; climatic influences for a similar purpose; regulated exercise and an outdoor life after the more acute congestion has subsided, again to prevent internal congestions. In the more acute periods, absolute rest, hot baths, hot fomentations or douches, alternating hot and cold fomentations, or, if perihepatitis, ice to the surface. Blisters are often not amiss; dry cups are of the greatest advantage, relieving pain and the sense of fulness the large organ gives rise to. Depletion of the intestinal tract by means of purgatives can aid wonderfully and must be resorted to, the salines being preferable. Many therapeutists are fond of flushing the liver by draughts of hot water taken in the fasting stomach. Finally the enlarged organ should be supported by a properly fitted abdominal bandage.

The character of the process of the next stage does not give encouragement for direct treatment. It is doubtful if any method of medication can arrest or mitigate the process. The lines of hygienic, dietetic and climatic treatment suggested above may measurably lessen the rate of growth of the exuberant tissue and lessen the tendency to catarrh of the ducts. That nature sidetracks the organ is seen in the cases which have proceeded to great length without any symptoms. It is reasonable to suppose the efforts carried out as described above contribute to this end and make an environment of the economy, compatible with the presence of a diseased organ.

But no treatment of a process can be thought of that does not include the oft-called etiological treatment. This has been hinted at in considering the management of alcoholic cirrhosis. Similarly, if we suspect a sclerotic process secondary to organic heart disease, the treatment of the antecedent condition is essential. Indeed, even though the symptoms are not patent, in organic heart disease all management looking to the prevention of sclerosis must be conducted. If we find again syphilis can be invoked as causal, we have other plans of medication to take up, which in time arrest or assuage the process.

The Symptomatic Treatment.—It is evident cases of the first score can not be included in any scheme of treatment; cases of the second score, if they survive the outbursting symptom of the process, must be managed according as they fall into the remaining classes. Cases belonging to the third class fall to our lot for medical treatment more frequently than any other class.

Portal Obstruction.—It will not be necessary to outline to an audience of the practical and scientific acumen of this Section, the methods of treatment, either of the gastritis and the enteritis or the secondary effects thereof. Such treatment is based on such general and established lines that methods are beyond cavil. A word of caution is not unnecessary regarding the treatment of hemorrhoids. This venous condition is frequently a result of cirrhosis, and it is well known is attended by such state of tissues that invite infection. I have seen disastrous results follow a more or less rash, and, perhaps, septic operation. Of course, a cure is not so readily obtained as in other forms of hemorrhoids.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. Frank Billings, George Dock and J. M. Anders.

Ascites.—Again it is not necessary to rehearse the broad methods of treatment by diuretics, diaphoretics and purgatives, which are the common property of us all, the principles guiding us in their use as well as the hygienic management being well known. I wish by permission, however, to make record of some drugs which have been of service in my experience and some methods which must be resorted to before we dare cry "quits." Of the drugs, I would mention calomel. Small doses, frequently repeated, act well as a diuretic and can be relied on in many instances in which the stimulating diuretics, as caffein, strophanthus and other forms have failed. One-tenth of a grain every three hours is a dose which in four or five days brings on diuresis and gradual reduction by this means, and perhaps by absorption of the fluid.

Apocynum cannabinum, in doses of fifteen, twenty or thirty drops, four times daily, has in my hands proved valuable in reducing the ascites. It will often act as a purgative, a not necessarily desirable effect, which can, however, be controlled by regulating the doses. The oleoresin of copaiba, in capsules of ten minims every four hours, has also proved efficient in my hands. If not contraindicated by gastric or intestinal conditions it is often the most satisfactory.

Often medication will not relieve the ascites so that the fluid must be removed. We must not postpone the operation. A too great faith in medication, when kept up too long, permits pressure effects of the ascites which are not desirable, and also invites chronic peritonitis. Delays are dangerous. Tapping, to remove the fluid, should be resorted to early; and it should be done as frequently as the fluid forms. Nature taps often by allowing the water to break the thin umbilical bounds and ooze from the wound. Who has not seen the aspiration hole leak and leak until all fluid is drained, and perhaps remains away? I have seen ascites cured and the cirrhotic process arrested after the one hundred and fiftieth tapping. A cure is recorded of a case which was tapped more than 200 times. If tapping becomes impracticable, as sometimes occurs from thickening of the peritoneum, abdominal drainage must be resorted to. The cures are not as brilliant as in tuberculous peritonitis treated in this manner. Nevertheless, great danger lies in harboring an unusual amount of fluid. Again, if relief is not afforded, laparotomy and stitching the omentum to the anterior abdominal wall, establishing a collateral circulation, must be resorted to. The brilliant results of Frazier and other recent operators establish the feasibility of the operation.

Obstruction of the Biliary Passages.—Here again for reasons previously outlined, it is not necessary to dilate upon methods of treatment. I would call attention to the necessity of resorting to surgical relief in cases of obstruction with cholangitis and cholecystitis. A private patient, age 54, with alcoholic cirrhosis of the liver, cholangitis and cholecystitis, suffered from rigors and fever every week, the violent and most prostrating paroxysm, bringing him almost to death's door each time. Professor Martin drained the gall-bladder, giving entire relief to the symptoms and prolonging life nine or ten months. A large experience with these cases leads me to advise such operation early in the disease.

DISCUSSION ON SYMPOSIUM ON SOME CIRRHOSES OF THE LIVER.

Dr. Frank Billings, Chicago—There is no doubt but that in hepatic cirrhoses prominent symptoms may occur from what Dr. Stockton has indicated, first of all, from the obstruction to the circulation which manifests itself in ascites, or in dilatation of the veins, forming a collateral circulation, the ascites not appearing, but the intoxication occurring, especially in the atrophic form. Dr. Stockton has fully brought out this point. There are, however, points for discussion upon the cirrhoses considered from a clinical point of view. I have been surprised in the ordinary practice of medicine to find how frequently one discovers cirrhosis of the liver that is not advanced enough to produce either an ascites, nor, probably, a classic intoxication such as Dr. Stockton has indicated. There is a cirrhosis of the liver which can be detected by palpation; ordinarily one can not feel the liver and recognize it in the healthy state, everything else being equal; but when that liver becomes cirrhotic we may detect its edge. I have been surprised to find a large number of ambulatory cases in which the liver was palpable.

Dr. Musser has referred to congestion of the rectum being present in cirrhoses of the liver without there being visible hemorrhoids; in this the cirrhosis of the liver is sufficient to produce a slight mechanical effect upon the circulation, producing a proctitis, or, at least, producing enough congestion to cause bearing-down pains and pressure. This I have frequently seen, and I have frequently prevented surgical operation by medical treatment directed to the liver, which caused the hemorrhoids to disappear.

There is a form of cirrhosis of the liver that has passed the beginning stage, which has some relation to intestinal intoxication; it certainly has some relation to intestinal disturbances. For, if one places a case of that kind under good hygienic surroundings, with a proper selection of food, with attention to the excretions of the body, and especially to the unloading of the portal circulation by some simple means, the palpable liver will soon cease to be palpable. Years ago —nearly twenty years ago, I think—I read an interesting paper by Kussmaul upon muriate of ammonia; he administered this in the early stages of hepatic cirrhoses, claiming that it prevented proliferation of the connective tissue cells and so cured the cirrhoses in the early stages. Since then I have used muriate of ammonia in many cases of liver cirrhosis with the result that the induration has diminished and even disappeared. Perhaps the hygienic measures coincidently practiced may have produced the good effect ascribed to the drug.

Associated with mild cirrhosis of the liver there are symptoms of intoxication differing somewhat from those mentioned by Dr. Stockton. Many patients complain of lumbago-like symptoms; others of sciatic pain; others of musculo-spiral pain. They have this autointoxication, but it is not associated with drowsiness and hebetude, such as appears in true intoxication due to cirrhosis of the liver. In many of these cases I have found a hard, palpable liver, and, under the treatment mentioned, the symptoms have disappeared.

Dr. James B. Herrick, Chicago—We have heard much from Dr. Musser and from Dr. Stockton regarding the treatment of cirrhoses of the liver and they have dwelt upon the treatment of the milder cases of this disease, or the treatment of the disease in its incipiency. It is an extremely hazardous thing to venture a diagnosis upon symptoms of "biliousness," and yet the more one studies these cases the more one is inclined to view "biliousness" as an important diagnostic aid. A patient with coated tongue, headache, who is drowsy, with alimentary disturbances, with a sense of weight or pain in the right hypochondriac region, with a palpable liver, who is alcoholic, perhaps with hemorrhoids, can be suspected of having an incipient cirrhosis of the liver; and if there is any time in the history of this disease when we can do any good it is in the beginning. It has been my experience to see a few of these cases that have improved under treatment and I have ventured to place upon the history sheet, with an interrogation point after it, "beginning cirrhosis of the liver." Proper diet, with attention to the alimentary canal, and the giving of laxatives seem to do the most good. I have used, empirically, muriate of ammonia, because Dr. Billings had told me of his experience with it, and I wish to confirm what he has said in regard to its efficaciousness in these cases. Another remedy that I have used, in a measure empirically, is the salicylate of sodium.

Musser has referred to several cases in which operation has been successful. I have never been convinced of its advisibility in all cases and I would not advocate an operation save in exceptional instances. Not long ago I had a very instructice case occurring in a patient with atrophic cirrhosis of the liver. He was about the wards of the hospital for months. He had an ascites which was repeatedly tapped but it as often recurred. This patient was bothered a great deal by a large umbilical hernia which one day became strangulated. He was removed to the surgical wards and an operation was performed successfully. At the time of the operation a large amount of ascitic fluid was released. The liver was examined by touch and sight and found to be a typical one of atrophic cirrhosis. After the operation that man never had a recurrence of the ascites. One year later he died of pulmonary tuberculosis.

Dr. Musser has referred to chills and fevers. The most typical case of chills and fever ever seen by me was in a patient in whom there were daily paroxysms, and these paroxysms lasted for many months; this was a case in which I believed there was a hypertrophic cirrhosis of the liver with jaundice. The patient died from hepatic intoxication. An operation had been advised but was refused by the patient. Punctures of the liver revealed no pus and no micro-organisms. There was no reason to suppose the patient had gallstones. There was no malaria present. That chills and fever do occur in cirrhosis of the liver has been shown by quite a number of writers. Riva, for example, has dwelt at length upon the occurrence of chills and fever in cirrhosis of the liver and in syphilis of the liver.

Dr. Futcher's paper was very complete and it deserves discussion, but I do not feel competent to discuss it because I have never seen a case of hemochromatosis, except one—perhaps the case he referred to—shown by Dr. Osler at another Association. The thought has occurred to me whether or not there could be any connection between the purpura and the cirrhosis of the liver. Is the purpura the result of a toxemia or it it possible, on the other hand, that the repeated extravasation and disintegration of the blood can give rise to pigment and secondarily to the cirrhosis?

There is a cirrhosis of the liver called by the French a "mixed cirrhosis." We have cirrhoses of the liver that are clearly recognized, clinically and postmortem, as atrophic cirrhoses; on the other hand, we have cases that are just as clearly hypertrophic cirrhoses. I know that in practice I am frequently in doubt as to what name I am to apply to a given case of cirrhosis of the liver, for, in many cases, some features are those of the atrophic form and, in others, of the hyperthropic form. I have found that, in many cases, even the pathologist is in doubt, even when he has made a microscopic examination, because certain pathological findings are found that fit in with the atrophic form, and others that fit in with the hypertrophic form of cirrhoses. The French have described a "mixed cirrhosis" and it seems to me not only a convenient term to apply but one that is justified on clinical and pathological grounds. Patients who are jaundiced for three or four years, having frequent attacks of "biliousness," who become weak and lose weight, whose livers and spleens are enlarged with symptoms that denote obstruction to the portal circulation, we say are subjects of hepatic cirrhosis, and they die of hepatic intoxication. Such cases present some features of both forms of the disease; they are really "mixed" forms of cirrhosis.

Dr. Musser has also referred to the importance of hemorrhoids in cases of cirrhosis of the liver. I should also like to say, aside from the subject, that one should never forget to make a rectal examination for carcinoma of the rectum in cases of hemorrhoids.

Dr. William E. Quine, Chicago—The feature which has directed my attention more frequently than any other in this connection is one concerning the early identification of cirrhosis of the liver before ascites has made its appearance. Those of us who have been long engaged in the practice of medicine were taught that the identification of cirrhosis of the liver could not be made with any degree of certainty before ascites had made its appearance, but increasing experiences of this kind have taught us that an array of phenomena ordinarily makes its appearance pointing to its possibility and the diagnosis of chronic interstitial hepatitis may be safely predicated; there are evidences of auto-intoxication connected with the establishment of the collateral circulation which permits the blood from the gastro-intestinal canal to gain an entrance to the systemic circulation without passing through the liver; this furnishes by far the most important and striking of these phenomena. The symptoms have already been dwelt upon with a sufficient degree of minuteness which obviates the necessity of referring to them again. Dr. Stockton has directed attention to the liability of gastrorrhagia, associated with evidences of diminution in the size of the liver and more or less enlargement of the superficial veins of the abdomen. In the absence of ascites and the presence of these other phenomena he was able to predicate with some precision the liability of the occurrence of gastrorrhagia. This is a point in the early diagnosis of chronic interstitial hepatitis that is entirely new to me, but I am now ready to expect it and I have no doubt whatever, as I ruminate upon my own experience, that it is a point of value.

In relation to the treatment of cirrhosis of the liver, and particularly to the early treatment of it, my experience has been similar in kind to that of some of the gentlemen who have spoken and to some of the essayists who have introduced a consideration of the subject. I have never known any diuretic to make any impression whatever upon the ascites of cirrhosis of the liver. So far as I know the administration of such diuretics as digitalis, squills, calomel, or blue-mass, or any of those mentioned, uniformly fails to make any impression whatever upon the clinical course of the disorder. I have used the chlorid of ammonia. During the whole of my professional career, until quite recently, I have treated these patients exclusively upon the basis recommended by German writers. Unlike my esteemed colleagues I have never found any remedy which was of value in the early treatment of cirrhosis of the liver such as they claim for chlorid of ammonia. It is a medicine of very small utility. So far as any medicinal treatment of this disease is concerned the most efficacious consists, in my opinion, in the administration of moderate doses of hydragogue purgatives with a view of depleting directly and persistently the portal circulation. An auxiliary is to be found in the application of a firm bandage to the abdomen.

In my experience the omission of the application of a firm bandage immediately after the abstraction of the ascitic fluid by tapping or aspiration is a step that no practitioner can well afford to omit. The systematic and thorough bandaging, I do not hesitate to say, lessens the rapidity with which the ascitic fluid returns and, I have thought, increased the rapidity with which the collateral circulation is established.

I have had no experience with the establishment of permanent drainage, but it is a procedure which commends itself to me. I have had but little experience with the operative treatment of ascites due to cirrhosis of the liver. The case referred to by the speaker who just preceded me came under my notice after it had been operated on; it was one in which an operation was demanded in the course of a cirrhosis of the liver by reason of the occurrence of a strangulated umbilical hernia. In one other case that came within my knowledge the operative treatment for cirrhosis of the liver was promptly successful. If I was asked to choose now between these methods of operative treatment I should have recourse to permanent drainage before undertaking to establish vascular connections between the omentum and the parietal peritoneum, or between the omentum and the peritoneum lining the undersurface of the diaphragm.

Dr. William Bailey, Louisville, Ky.—In most of these forms we have gastro-intestinal disturbances which must be controlled by abstaining from alcohol, by proper dietetic regime, etc., and I am sure that by the administration of such remedies as phosphate of sodium, muriate of ammonia, etc., we shall accomplish some good. Where there is auto-intoxication, instead of giving the mild chlorid, I believe in the use of the bichlorid on account of its disinfecting influence upon the gastro-intestinal canal. That canal should be drained by means of saline cathartics, such as phosphate of sodium. I have had no experience with the surgical features, except by tapping. The circulation in the liver is better after tapping and drainage; therefore, I do not think we should allow the pressure to exist which comes from the increased accumulation of the fluid.

Dr. O. T. Osborne, New Haven, Conn.—I think we should be somewhat chary in making a diagnosis of beginning cirrhosis of the liver with simply the so-called bilious symptoms; we may have conditions of biliousness in intestinal indigestion, with headaches, etc., in which there may be some congestion of the liver which will give a slight enlargement that is not at all a beginning cirrhosis of that organ. Many cases that are treated as a gastritis are really trouble in the duodenum, and I think inflammation of the duodenum is of frequent occurrence. For a long time ammonium chlorid has been supposed to be almost a specific in inflammations of the mucous membranes of the air passages, but I believe that it is just as specific for inflammations of mucous membranes anywhere. If there is a catarrhal inflammation of the gall ducts giving symptoms of biliousness it is certainly well treated by this drug; it improves the condition here in the same way that it betters a bronchial catarrh. The congestion in the duodenum, or in the ducts, give a diminution in the amount of bile which should be thrown out into the intestine; therefore, we must get intestinal fermentation and an intoxication causing the bilious condition. Now, we know that salicylic acid is one of the best antiseptics that we have; hence, this drug would be a correct treatment.

I can not help but ask a question in connection with the treatment by anastomosis. We know that, in cases of tuberculosis of the peritoneum with a large amount of ascitic fluid, simply opening up the abdominal cavity is productive of great good. I should like to ask how much the opening of the abdomen and how much the anastomosis had to do with the good results obtained in the case reported by Dr. Herrick?

Dr. Robert B. Preble, Chicago—I should like to speak of a limited experience with the Talma operation. I have found in the past four years but two cases of atrophic cirrhosis in which operation seemed to be justifiable; one of these died immediately from the effects of the operation, and in the other, *the operation did not produce any beneficial effect. Since* the operation the second case has been tapped at intervals of ten to fourteen days and, so far as can be seen, there has been no effect except that upon the abdominal wall there is now developing a fairly well-marked collateral circulation which was not present before the operation. I have seen but one case in which the operation was followed by brilliant results.

I wish to question a statement that has been made in reference to the presence of hemorrhoids. Lécorché has stated that hemorrhoids are not more common in cases of atrophic cirrhoses than in patients in general. When I first read this statement I was very much surprised, but since then I have particularly inquired into this question and I must confess that it is a correct statement. Hemorrhoids are not more common in atrophic cirrhosis of the liver than in patients in general.

Gastric hemorrhages due to atrophic cirrhosis are more common than formerly supposed, although strictly speaking these hemorrhages are not gastric; a better term would be "esophageal." A very small portion only of the hemorrhages are from the stomach, but it comes from the veins above the cardiac end of the stomach. The lower end of the esophagus bears somewhat the same relation to the portal circulation as does the rectum; the blood there fuses in somewhat the same way with the systemic circulation as it does about the rectum, although the physical conditions are different. The veins of the lower end of the esophagus are within the thorax, and the abdominal are not. With each inspiration a negative pressure is created within the thorax and in a way aspirates the blood directly from the portal veins into those above the diaphragm. This would favor the development of anastomoses between the veins of the stomach and those of the esophagus, so much so that we would expect the varices to be more common in the esophagus than they are. It is easy to see how the veins of the esophagus could be injured by the passage of a rough bit of food or some instrument and hemorrhage result.

It is extremely difficult to differentiate these hemorrhages from those occurring in ulcer of the stomach. I have had a personal experience in five cases in which such hemorrhage occurred and all had these points in common: all were beyond 40 years of age, one being 55; all were addicted to the use of alcohol; all were taken with hematemesis when at work and there were none of the ordinary symptoms of gastric ulcer present. After the occurrence of the hemorrhages they all died, and it was then found that the source of the hemorrhage was an ulcer of the stomach.

Dr. G. W. McCaskey, Fort Wayne, Ind.—I wish to mention a case which, according to the facts stated by Dr. Musser, comes close to the "high-water-mark" with reference to the number of tappings for ascites. The patient was under the care of my colleague, the late Dr. James S. Gregg of Fort Wayne, and during my association with him in the case about one hundred and twenty aspirations were made. The patient then removed to Chicago where frequent tappings were kept up until his death two or three years later and it is probable that he was tapped one hundred and fifty times.

Concerning the etiology of cirrhosis of the liver, I wish to emphasize the importance which I attach to clinical observation of primary disease of the gastro-intestinal tract. There is a large group of cases which I believe, as stated by one gentleman in this discussion, have their origin in these conditions. While the statement is not susceptible of demonstration, I believe it is a fact that in the majority and perhaps in all cases of chronic gastro-intestinal disease we have at least an initial cirrhotic condition of the liver. Boix, in his little brochure on the liver of dyspeptics, says, if I remember correctly, that it is not so much the result of the alcohol as of the gastritis and enteritis due to the alcohol. My own observations in dealing with a large number of chronic cases of this character leads me to practically the same conclusion. Of course, there are other causes for cirrhosis of the liver which I will not consider.

Dr. Clarke Gapen, Madison, Wis.—I do not believe that anyone can fail to be interested when he takes up the subject of ptomains and notes the enormous number of new clinical combinations that are produced as the result of decompositions occurring in the intestinal tract, some innocuous and others exceedingly poisonous. In investigating this question I have come to the conclusion that, in nine out of ten cases, the true explanation of the so-called liver of intoxication is the development of some of these poisonous substances which are absorbed into the blood and so find their way to the nervous system and liver tissue and so produce their effects. Therefore, as the result of my own experience, I have, for some time past, pursued a treatment that was directed towards the prevention of such decompositions and the elimination of their products. One gentleman has alluded to the salicylate of sodium as being of value in these cases and I have no doubt of his correctness, but I have found that this agent is exceedingly irritating and decomposes in the upper alimentary tract and so is liable to aggravate the condition. I remember a case occurring two years ago which had resisted almost everything; it was characterized by alternating constipation and diarrhea with offensive stools, etc. In this case I used guaiquin, which is a combination of guiacol and quinin, and within three days all the symptoms disappeared. I think that of all remedies pure water in large quantities is the most effective. This idea was suggested to me by the methods in vogue at one of the noted mineral springs of this country. The patient there is directed to drink two glasses of water; then walk a mile; then drink two more glasses, and walk a mile; and this is kept up until the alimentary canal is washed out and the toxemic symptoms disappear. I give water in these cases with the principle in view that if water is poured in at the top of an open tube it will run out at the bottom. I have had, recently, two cases in women who were profoundly bilious subjects and who presented symptoms of so-called liver toxemia whom I treated in this way with great benefit. The relief of the constipation was not sufficient in either of these cases. In both, however, I gave benzozol, which breaks up in the lower part of the alimentary tract well down in the small intestine; guaiquin will also do this and is an excellent tonic remedy as well as an intestinal antiseptic.

DR. GEORGE W. WEBSTER, Chicago—I wish to call attention to one or two symptoms occurring in those cases where there is a considerable collateral circulation established, and in which ascites develops suddenly. If the belly be tapped the fluid rapidly refills and the patient goes on to a rather speedy death in spite of the treatment. During the past two years I have seen two cases which came to autopsy. In one there was no ascites at first but there was a large collateral circulation established; later ascites occurred very suddenly; the patient was tapped, but within thirty-six hours the enlargement of the abdomen was as great as it was before; the fluid reaccumulated in spite of frequent tappings, and the patient died within six weeks.

In another case, there was a fair amount of fluid in the abdomen, but very little collateral circulation. In this case, too, there was a very rapid re-accumulation of fluid, the abdomen refilling within thirty-six hours after tapping. A thrombus of the portal vein was found at the postmortem in both these cases. I think it was Welsh who first called attention to this point.

It has been my experience to find that the inferior hemorrhoidal veins are enlarged; but more often there is an enlargement of the veins in the lower end of the esophagus. All of these cases have gastro-intestinal symptoms and many times patients come to the physician for treatment of some stomach trouble and it is very common for them to receive such routine measures as the Ewald test breakfast with washing out of the stomach; the introduction of the stomach tube has often been followed by fatal hemorrhage. Therefore, one should be very careful not to permit instrumentation of the esophagus in cases where we suspect varicose veins.

DR. W. H. NEILSON, Milwaukee—I am disappointed in the fewness of allusions made to the treatment of hypertrophic cirrhosis because our patients certainly suffer greatly from the nervous phenomena, the itching, and the other symptoms that are produced by the presence of bile, and yet we are not able to find any treatment for their relief. I merely rise to ask if there are any gentlemen present who can relieve these symptoms of this particular form of cirrhosis?

DR. CHARLES G. STOCKTON, in reply—I should like to get a little better understanding of Dr. Preble's views in the matter of the dilatation of the hemorrhoidal veins. I think that the Doctor will agree that the hemorrhoidal veins are very greatly enlarged, as a rule, in atrophic cirrhosis of the liver; but it does not always follow that there is a development of hemorrhoidal tumors with large descending hemorrhoidal veins. I fully agree with the statement that enlargement of the hemorrhoidal veins is constant in the atrophic form of cirrhosis of the liver. The criticism of the term "gastrorrhagia" when the hemorrhage occurs in the lower part of the esophagus is well taken by Dr. Preble; it is often esophageal in origin, but not always so.

DR. FUTCHER, in reply—I had hoped there would be more discussion on the subject of pigmentation in association with cirrhosis of the liver. I attribute the lack of discussion to the fact that this disease is undoubtedly very uncommon, as shown by the fact that only four cases have been reported in this country. I should like to utter a word of warning against the possibility of these cases being mistaken for Addison's disease. In the particular case of which I read brief notes a provisional diagnosis of Addison's disease was made when he first came under observation, but the existence of an enlarged liver and spleen and the presence of hemosiderin in the cells of the sweat glands and rete malpighii.

I am glad that Dr. Herrick referred to the possibility of purpura being a cause of cirrhosis of the liver. I might say that in Anchütz's series of 24 cases evidence of a hemorrhagic diathesis was present in only 6 cases. Purpura was present in moderate degree in 3 cases; in 1 case there was epistaxis; in another hematemesis and the sixth had hematuria. It will thus be seen that purpura did not play a very important part, either primarily or secondarily, in this series.

I should like to refer to a case at present in Dr. Osler's service at the Johns Hopkins Hospital. It is a case of purpura, of seven years' standing, occurring in a man 33 years old. During this time he had almost persistent purpura and he now has a diffuse purpura eruption below the level of the waist. An interesting feature of the case is the markedly enlarged liver and spleen. Dr. Herrick's suggestion that there may be an absorption of blood pigment in such cases, with consequent enlargement of the liver and spleen, is quite apropos in this case. It is possible that this case may be an anomalous form of hemochromatosis.

In regard to the experience with the surgical treatment of ascites at the Johns Hopkins Hospital, I may say there have been six cases operated upon by Dr. Bloodgood and Dr. Mitchell with, I think, results that have justified the operation. The first case was operated on by Dr. Bloodgood four years ago. He gave a marked alcoholic history. The usual operation of stitching the omentum to the abdominal wall was performed, and the patient was cured of his ascites, which has never returned. It is four years since the operation and this man has continued taking alcohol in large quantities and whenever he reports to Dr. Bloodgood he is in an intoxicated condition. This satisfactory result under such unfavorable conditions is very encouraging. In the second case operated upon there was but a temporary improvement. Two cases were not improved by the surgical interference. One case died twenty-four hours after the operation. There is now one case under observation in the hospital who was operated upon two or three weeks ago and up to the present time has been markedly improved. Nature had already set up an anastomosis between the omentum and the abdominal wall to which it was quite adherent. The transverse colon was also adherent to the anterior abdominal wall and in the adhesions large blood vessels were found.

A CASE OF ACROMEGALY PRESENTING CERTAIN FEATURES OF UNUSUAL INTEREST.*

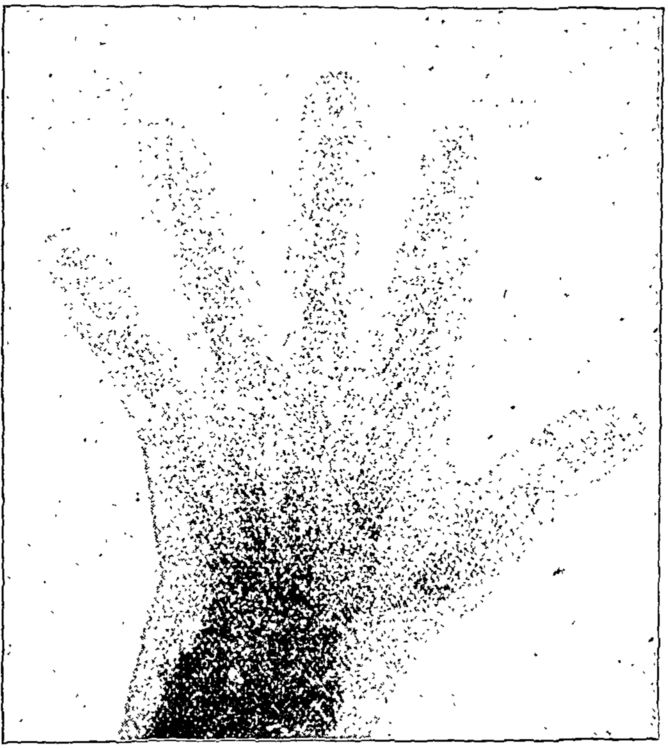
CHARLES LYMAN GREENE, M.D.
Clinical Professor of Medicine and Physical Diagnosis in the University of Minnesota; Attending Physician, City Hospital, St. Luke's Hospital Free Dispensary, Etc.
ST. PAUL, MINN.

In 1886 acromegaly was first introduced to the medical world, through the report of Marie, the name having been applied by him to a disease characterized by a progressive enlargement or overgrowth of certain portions of the body, all tissue being more or less involved, and the hands, feet and face being the earlier and chief seats of the morbid change. There can be no doubt concerning the close relation of acromegaly to giantism; indeed, it may be regarded as a sort of localized giantism. due to certain limitations in the pathologic seat and process, or to the age at which the disease begins. Acromegaly is so strikingly objective in its symptomatology that one finds it difficult to explain how it could have been disregarded for so many centuries. Up to 1891 only 37 cases had been reported, yet in 1893 the number had reached 83; in 1898, 218 had been reported, and at the present time nearly 300 cases are on record. Even this number does not rob it of its claim to rank as one of the rarest of diseases, nor has it in any way lost its interest for the clinician and pathologist.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. Frank Billings, George Dock and J. M. Anders.

Souza Leite, in 1890, first pointed out the fact that in nearly every case it was possible to demonstrate an enlargement of the pituitary gland. This curious gland, normally weighing but half a gram, has been found the size of a hen's egg or even larger, and by its peculiar structure suggests the possession of a double function. In its development its relation to both glandular and nervous structures is evident as its anterior portion is developed from the ectoderm of the buccal cavity, its posterior lobe from the fourth ventricle. The anterior portion is glandular in structure; the posterior contains nervous tissue and a close analogy to the thyroid gland is suggested. It is supposed to possess receptive, selective and elaborative functions. The possible connection between diseases of these two bodies, and hence between myxedema and acromegaly, is suggested by the fact that in myxedema the pituitary body is often enlarged, while in acromegaly the thyroid is frequently the seat of a sclerotic process.



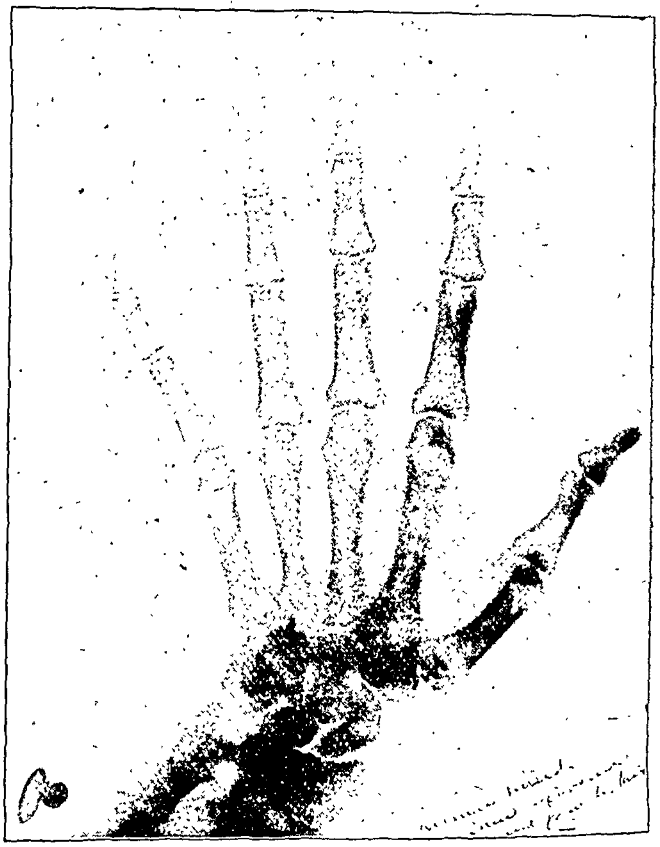
Author's case of Acromegaly.

A. Hymanson reported a case in the *Medical Record* of July 1, 1899, in which the close relationship or coincidence of these two diseases was distinctly suggested, and one of the most interesting features in the case reported below is found in the apparent combination or coincidence of the two diseases. In my patient there are also certain divergences from the type, which make the case one of peculiar interest. Exceptional opportunities have been offered for close observation, extending over a period of three years.

CASE REPORT.

The young man, Girard, is 25 years of age, has had no fixed occupation, but for some years prior to the development of the disease had spent the winter months on the ice, being employed as an ice-cutter, a point of some importance, inasmuch as the history of many of these cases has strongly suggested the influence of prolonged exposure to cold and dampness as a predisposing or exciting cause. The family history is negative. Lues venerea is denied, and there is no history of past illnesses of any importance. Three years ago he suffered from swelling of the knee-joints, which he naturally associated with his winter occupation; he also suffered from lassitude and a certain amount of general weakness, which prevented any steady work. Two years before this time, that is, five years ago, or at the age of 20, he noticed a rapid enlargement of the hands and feet, and the members of his family noticed and commented on the change in his physiognomy.

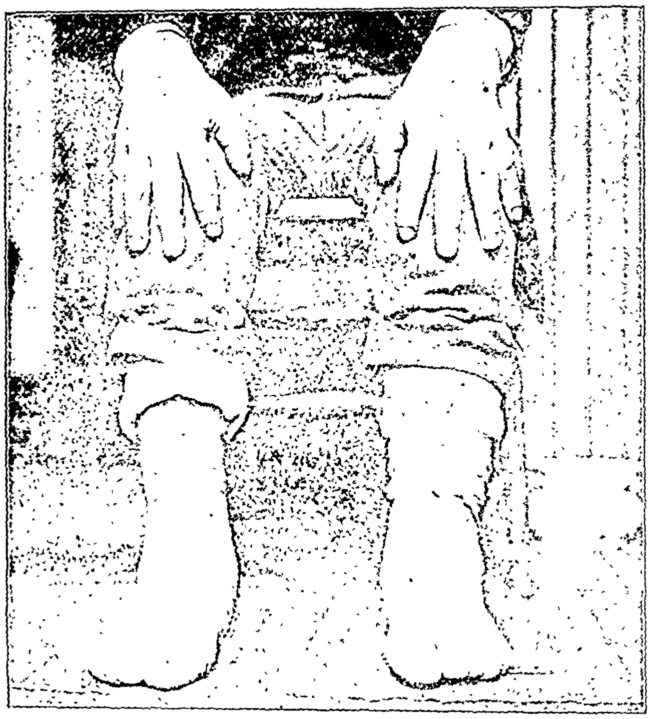
The enlargement of the hands and feet steadily continued and progressed quite rapidly up to the time that he presented himself in the writer's clinic, three years ago. At that time the following description of his appearance was placed upon the case record:



Normal hand, same exposure and focal distance.

> The hands and feet are enormous, the wrist and ankles free from inflammation but bulky, thick and in strong contrast with the forearms and legs, which in the upper four-fifths of their length are quite normal. The patient complains of langour and weakness but has had none of the severer vertical pains so common in acromegaly, nor does he complain of pain in the lumbar region or limbs. There are no signs of disturbance of the special senses nor of the nervous system. The skin throughout the larger portion of the body is nearly normal and lacks the harshness of myxedema. The appearance of the face is especially interesting; there the skin is thickened and hypertrophied, though not rough. Deep furrows have formed over the frontal region, both upper and lower eyelids are thickened and the ears appear clumsy and tumid. The superciliary ridges project, the nose is large and tumid, the nasal arch is prominent, the malar bones project markedly and the lower jaw, while not distinctly prognathic, is apparently enlarged both from the angle to the symphysis and vertically. The upper jaw is enlarged and the patient's attention has been called

to that fact by the gradual separation of certain of the teeth and by the marked forward projection of the superior dental arch. The enlargement of the upper jaw has no doubt masked the changes in the lower jaw, depriving the case of one of the so-called typical signs of the disease. Both the upper and lower lids are thickened and clumsy, the tongue is large but not excessively so, the larynx is enlarged as well, and its cartilages are apparently the seat of hypertrophy. No deformity of the spine or chest exists, nor are there any marked changes in the clavicles or the scapulæ. The fundis oculi is normal and the hands present the usual spade-like appearance with the sausage-like fingers and square, flat nails showing longitudinal striation. The radiograph demonstrates the remarkable enlargement of the bones both in length and thickness. The process seems to involve the lower fifth of the adjacent long bones, and of their overlying tissues, which present the same typical characteristics as the hands. There is no marked enlargement of the great toe, such as has been described in several instances; neither the hands nor the feet are the seat of pain, nor are their movements much restricted. A feature of especial importance, however, is the marked increase in the bulk of the overlaying tissues, which present the appearance and the sensation of a hard edema exactly like that of myxedema. Aside from the presence of dulness over the manubrium the internal organs seem to be normal. This dulness is supposed to be related to persistence of the thymus gland, a condition to which some writers would ascribe a great deal of importance and which some late investigators have shown to be present in a remarkably large proportion of these cases. The condition of the knees is simply indicative of chronic synovitis, the synovial sacs being tightly distended by the contained fluid. This description applies well to the present condition, save that the bony enlargement seems to have progressed, while the soft parts have shrunken to a marked degree.

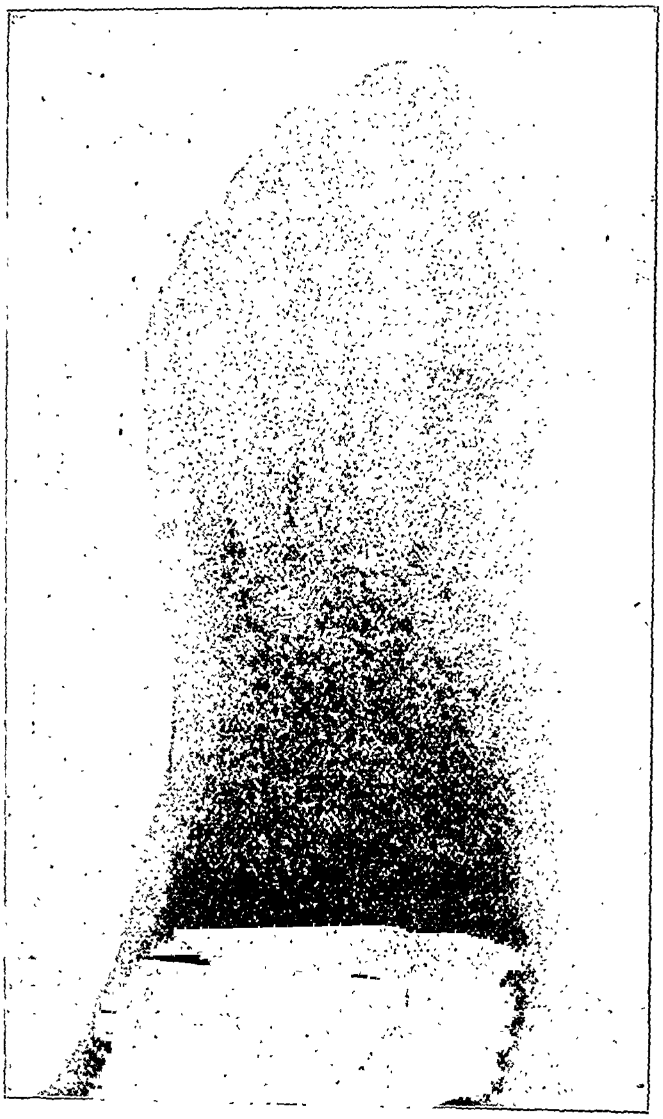


Author's case of Acromegaly.

The case seems to the writer to present several features of marked interest. It is sufficiently typical to make the diagnosis absolute: at the same time it lacks the marked prominence of the lower jaw and in certain respects strongly suggests myxedematous change. For the past five or six months the patient has suffered from cystitis due to a neglected specific, urethritis. This is slowly subsiding and it does not appear to influence the original disease in any way. The examination of the blood reveals nothing abnormal. The treatment has been solely by thyroid extract, the result being an immediate and marked amelioration of the myxedematous condition.

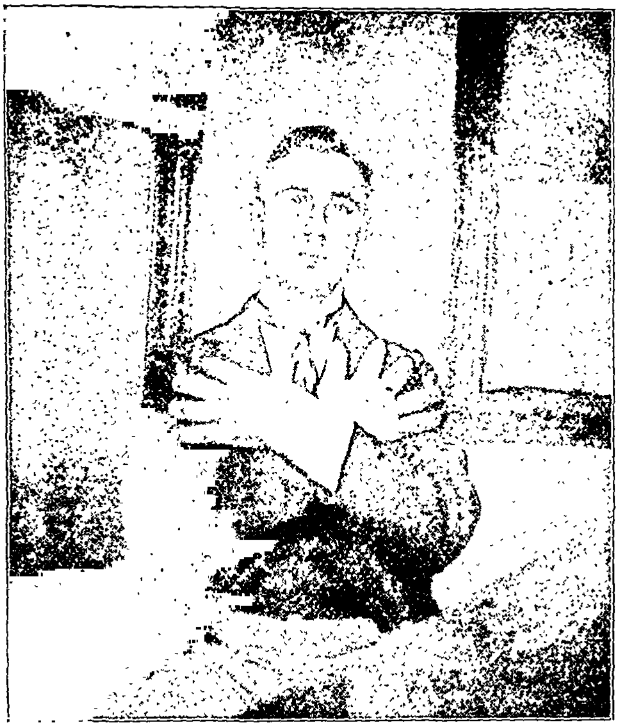
DIAGNOSIS OF ACROMEGALY.

Difficulties in connection with the diagnosis of acromegaly can rarely arise. The late symptoms are so striking that they offer an excellent opportunity for street-car diagnosis, and when fully developed the disease would seem to be quite unmistakable. It is customary, however, to point out the differences between acromegaly, osteitis deformans, myxedema and pulmonary osteo-arthropathy, though no one can hardly confound these diseases when they are fully developed. In the earlier stages myxedema and pulmonary osteo-arthropathy may offer some difficulty, and the following facts should be borne in mind:



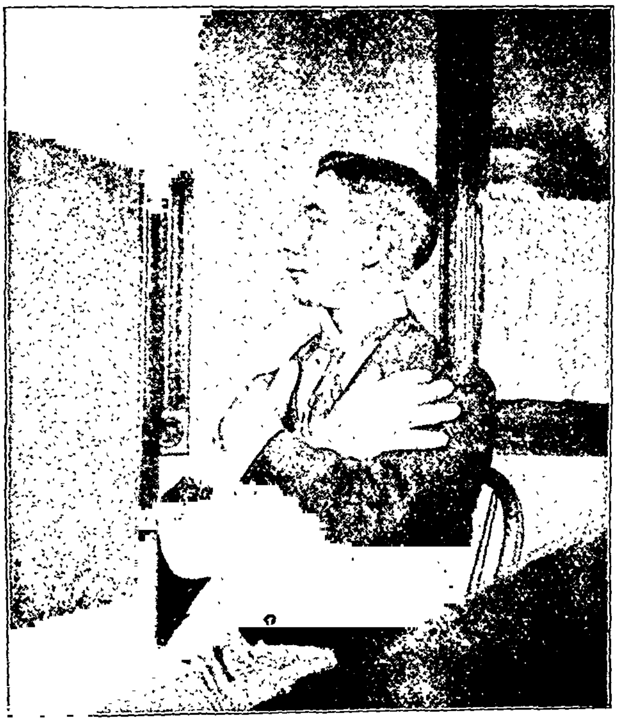
Author's case of Acromegaly. It will be noticed that a decided change is taking place in the great toe, though simple inspection does not reveal it.

Myxedema.—The hands and feet appear to be the seat of a hard edema—this symptom is present in this case—but the bones remain unchanged and the face is full and round, rather than ovoid, as in acromegaly. There is also well marked involvement of the soft tissues, falling of the hair, very often extreme tenderness over various portions of the body, and marked mental depression, apathy or irritability. In certain cases of acromegaly, as in this, it seems certain that myxedematous change is present, and pathologic research and the fact that some patients improve for a time under thyroid would indicate that the two conditions may coexist in the same individual.



Author's case of Acromegaly.

Osteitis Deformans.—The hands and feet are here unaffected and the cranium and shafts of the large bones are chiefly involved.



Author's case of Acromegaly.

Giantism.—This is symmetrical excessive growth and need not be confounded with acromegaly, though it is probably almost identical in etiology. Curious examples of localized enlargement affecting a single member have been noted, and in a case of acromegaly reported by Dr. Kanthack, the second toe of one of the enlarged feet was enormously hypertrophied.

Pulmonary Osteo-arthropathy.—In this disease the bones only are involved and the face is usually normal; the joints are often swollen and painful and there is usually a chronic pulmonary lesion. Moreover, the appearance of the hand is wholly unlike that presented by acromegaly, the changes being chiefly in the distal phalanges, which are clubbed and carry an elongated, curved nail.

PROGNOSIS.

These cases progress slowly, often lasting twenty to thirty years, tending to death by exhaustion, syncope or intercurrent disease.

TREATMENT.

The treatment of acromegaly has not kept pace with its pathology. Thyroid is sometimes of temporary benefit, and the pituitary body has been administered without marked effect. The conjoint administration of both remedies would seem to be indicated in my case. Marie has advocated the iodids, and others have spoken well of arsenic. Until we know more of this strange disease all treatment is at best a "forlorn hope," and our patient can hope for little aid or comfort at our hands.

Note: The clavicles and ribs now show marked enlargement.

THE INCREASING STERILITY OF AMERICAN WOMEN.*

GEORGE J. ENGELMANN, M.D.
BOSTON, MASS.

This investigation is based upon 1700 cases in private and dispensary practice in St. Louis: 1146 American-born, 357 Irish and Germans, 197 negroes. The Americans are grouped into the laboring class from dispensary practice, and the higher class from private practice; amongst these I have distinguished the native American, the American of American parentage, and the American of German and of Irish parentage; in addition, there are 2038 women taken from the genealogical records of Massachusetts.

The results obtained indicate that at the present time *20 per cent. and over of married women are childless,* whilst in the preceding centuries, in the earlier days of the country, only 2 per cent. were sterile; and when we compare these figures with the generally accepted rate of sterility, 11 per cent., found by Simpson and so generally accepted as to be called "Simpson's law," the difference is so great that it would appear that proof is needed before these facts can be accepted; it seemed impossible that sterility should have increased to such an extent in this country and that it should here be so much more common than in Europe.

To secure this proof I add the study of other records and of other of the phases of woman's functional life which are closely correlated; fecundity, intimately associated with sterility, varying in an inverse ratio, and miscarriage and divorce, which are directly parallel with childlessness.

This was necessary, too, because statistical and reliable data with regard to sterility are not numerous. Such as can be found I have here presented, mainly culled from gynecological writers; facts from other sources also were necessary to corroborate my results; valuable for this purpose have been the unpublished records from the dispensary of Dr. Chadwick in Boston, which he has kindly placed at my disposal, 1374 Americans, likewise grouped as Americans or American parentage and of Irish parentage, and 754 Irish. The vital statistics of Michigan, by Dr. Cressy L. Wilbur, afford valuable data as to fecundity among Americans and foreigners as in that state nationality of parents is noted. Similar data I have for Massachusetts from the unpublished manuscript of Dr. Kuczynski, elaborated from the state census, and this, in addition, presents statistics of sterility as well as fecundity. A proof more conclusive than any other one fact is the identity of my results with those deduced from the census of these two great states by the able statisticians who have presented them. The United States census gives only a very general estimate.

For the end of the eighteenth century valuable investigations as to fecundity in Massachusetts are to be found in the "Transactions of the American Academy of Arts and Sciences." Beigel, Mayer, Leudet, De Ott, Vogt, Szukits, Simpson and Mathews Duncan give important data for Germany, France, Russia, Norway, Austria and England, and Nathan Allen with regard to the New England states, Kuczynski for Massachusetts, and Wilbur for Michigan. Finally, for college women, Carroll D. Wright and Mrs. Mary Robert Smith in the United States, with Mrs. Henry Sidgwick in England, is our authority.

The facts presented corroborate my results in every detail and confirm the high sterility and low fecundity in the United States, conditions worse than in any European country save France, and for the native American population worse than that of France.

Definition.—It may be well to define the terms as here used, as they are not always applied in the same sense. By sterility I shall understand the condition of the woman who has been married three years without giving birth to a full-term child; by absolute sterility I hold to mean that she has never conceived; by relative sterility that she has conceived and miscarried, but has never given birth to a living full-term child;[1] abortion and miscarriage I shall use indiscriminately as indicating the expulsion of the ovum before the time of viability.

Sterility among the laboring classes in St. Louis is 21 per cent., varying in different groups 20.4 to 23.7 per cent.; in Boston 23.7 per cent., and 20 per cent. for all American born throughout the entire state, according to the Massachusetts census of 1898. My own records in private practice in St. Louis show 23.6 per cent. of native Americans barren and Americans of German parentage 26.3 per cent., an unusually high rate, which harmonizes, however, with the condition in Boston among Americans of Irish parentage, 27.2 per cent. An equally high sterility, in fact higher than among any other group, is attained by the college graduates, of whom comparatively few marry, and a large proportion of those who do marry are barren, 33.7 per cent. as reported in the investigation of 1885, and 20.5 per cent. in 1900, averaging 27.3 per cent. See Table 1.

My own records of Irish and German give only 17 per cent. among negroes, where invariably I find unfavorable functional conditions, 24 per cent. In Massachusetts 20.2 per cent. of Americans are childless, and only 13.3 per cent. of foreigners; Germans 11.2, French and Irish 11.6, English 14.4 and English-Canadians 19.5 per cent., closely approximating the American, which I have likewise found in all other functional relations, whilst the French-Canadians differ greatly, with a lower sterility and higher fecundity—in other words, with a more normal and healthy functional life.

---

[1] Properly speaking, this should include all those whose sterility is intentional, due to means of prevention; but these can never be all ascertained, not even can we determine with certainty all those who have miscarried. The result depends entirely upon the confidence of patient in physician, and the physician's skill in securing the history.

Foreign records show a great variation from the lowest sterility in Norway, 2.5 per cent., and in one of the districts near Moscow, 2.8 per cent., to 27.3 per cent. in Paris, Lyons and Rouen, in some of the departments of France only 16.8; in Alsace, whose inhabitants differ functionally as well as racially with a later puberty, sterility is very low, being only 3.5 per cent.[2]

Greater luxury and wealth invariably go hand in hand with higher sterility. Mayer of Berlin finds 25.7 per cent. among the higher and middle classes, and only 15 per cent. among the laboring classes. Sir James Y. Simpson found 16.4 per cent. among British peeresses, only 9.6 per cent. among a similar number of English villagers, but among English college women and alumnæ it is 27.6 per cent.. as it is among their American sisters. In Austria 7.4 per cent. is given.

* These figures should be somewhat less, as they indicate the number of children and miscarriages to the childbearing women and not to all married women: the number of miscarriages seems too small; on the contrary, as I am convinced that correct answers were not given, and for these records we must rely on the veracity of the patient.

The number of the absolutely sterile is greater than that of the relatively sterile, that is, the number of those who have never conceived, natural or artificial causes preventing, is greater than that of those who have borne no full-term child, but admit having miscarried one or more times. This deserves attention because it is a condition never before investigated, and barely referred to even by Mathews Duncan in his well-known work on sterility and fecundity. He says that no observations exist; he himself believes the numbers too few to merit attention. My investigation shows that in this country this group of relatively sterile, or as they are erroneously termed by some, secondarily sterile, is over 8 per cent. of all married women; that is, 8 per cent. admit the fact; the actual number is undoubtedly larger, as some conceal the truth and others who are willing to admit have not distinguished between an early miscarriage and a free flow. In my dispensary practice the absolutely sterile are 11.6 per cent. and the relatively sterile 8.8 per cent., and this number remains about the same, whilst the number of the absolutely sterile varies far more in the different classes; among Irish and Germans the relatively sterile are only 6 and 6.5 per cent., with 11 and 10.5 per cent. for the absolutely sterile. The absolutely sterile I find to be about 12 per cent. among Americans, and this practically corresponds with the so-called "law of Simpson," that is, one sterile woman in eight and four-sevenths marriages, or 11 per cent.; but I am convinced that he had reference to all sterile, as he makes no such distinction, and the classification has never before been made; moreover, it corresponds with the total figures for sterility which he gives—16 per cent. for the higher and 9 for the lower classes.

It is evident that the extremes of sterility are reached in this country, although the rate does not exceed, in fact, does not quite come up to that of France, which in large cities is greater, in the country less.

Miscarriage.—Few estimates exist as to the frequency of abortion, but the generally accepted proportion has been that of 1 miscarriage to 5.5 labors at term. Hegar is often quoted with his estimate of one miscarriage in the earlier months to 10 labors at term, which is about the same. I find one miscarriage to 2.8 labors at term. a little more in private practice, most among the native American, 1 to 2.77, and somewhat less, 1 to 3.03, among the American of German parentage; less still among foreigners, among the Irish only one miscarriage to 4.3 labors and among the Germans 1 to 3.6. (See Table 2.)

---

[2] This is the average of four years, 1872 to 1875, of 40,510 families in which either father or mother have died; hence, family life was cut short and many are noted as barren who in time might have borne children; on the other hand, these are the first years of German occupation during the option of migration, of which many availed themselves and these of course were in a great measure the more mobile childless families, so that an undue proportion of families with children remained; all in all the rate of sterility may be 1 per cent. or so below the correct average.

These figures are fully corroborated by the Boston records of Dr. Chadwick, who finds one miscarriage to 2.8 labors among all American-born in his dispensary, precisely as I do in St. Louis, namely, one miscarriage to 2.7 labors among Americans of American parentage and a trifle less, 1 to 3.06, among those of Irish parentage; among the Irish in Boston he finds 1 to 4. The actual number of abortions is 0.6 to 0.7 to each American-born wife and 0.96 for the Irish, 0.95 for the German, but the number of living children for foreigners is so much greater that the proportion of miscarriage to labors is reduced to less than it is among Americans.

Other available data I could discover none, save one German investigation which from 100 miscarriages deduces a proportion of one in 3.3 labors; this is likewise indicative of greater frequency than the accepted teaching of one miscarriage to 5.5 labors.[3] Although frequency of miscarriage is evidently greater in this country, it is not possible that it should be so much more frequent than it is in Europe; I am inclined to believe that the formerly accepted standard of 5.5:1 is vague and never was based on carefully studied facts, or that it is now antiquated and that the records of the higher classes in the larger cities of Europe would show a similar condition, yet I find but meager facts pro or contra.

We have found barrenness in the large cities of France greater than it is in this country, and I believe that the same would be true of miscarriage were the investigation to be made, but no data exist as to European conditions.

Fecundity.—Among the laboring classes in St. Louis I find 2.1 children to the married couple, and I here follow the universal custom of estimating the number of children to all marriages, i. e., to the number of married women, inclusive of the sterile, not only to the number of child-bearing women or mothers.

This is the highest fecundity which is found among the American born in this country (See Table 2), and I believe it due to the large admixture of the German element; it corresponds perfectly with the results found elsewhere; in Boston it is 1.7; in the state of Michigan in the last years 1.8, and for the twenty-five years from 1870 to 1895, it is 2.1, owing to the somewhat higher fecundity in the earlier years; it has there been slowly decreasing, as it has in every state in the Union. My private practice shows a fecundity of 1.7 among Americans of American parentage, less than in the dispensary, and a better condition, 1.9, among Americans of German parentage, precisely the same as among the Americans of Irish parentage in the Boston dispensary, whilst the Americans of American parentage there show 1.74, like the native American in St. Louis, a lower fecundity than anywhere recorded, unless it be in the French metropolis and among college women, English and American.

Very instructive and indicative are the observations made in regard to the effect on the reproductive function by one of the phases of modern female life, by overpressure in schools as shown in the study of fecundity among college graduates, by Carroll D. Wright, and later by one of their number, Professor Smith; there we find the very lowest fecundity, 1.3 and 1.8 (not 1.6 as Mrs. Smith figures it)[4] children to the marriage, an average of 1.6, which is corroborated by a similar group of women who have continued their studies longer, who have taken the advanced degrees, mostly Ph. D., with 1.6 and by English college women with 1.5. With this group of college graduates Mrs. Smith compares their relatives and friends of the same social class, whom she finds more prolific, with a higher fertility of 1.89 (really 2.1), which is precisely what we should expect from that class of American women, and harmonizes perfectly with the general average shown by my tables.

These figures clearly show the influence of college work and nerve exhaustion; among no group is fertility so low as among the college alumnæ; and this is corroborated by reports from England, where we find among female college graduates only 1.53 children to the marriage, whilst the average fertility of English women, as shown by the "Victorian Yearbook," is much greater, 4.2 children to the marriage. A comparison of these figures offers food for serious thought. The Michigan census and Boston dispensary give a trifle less than my own St. Louis records, but the same that I find among the higher class from which the group of sisters or non-college women is also taken.

TABLE 3. FECUNDITY IN THE AMERICAN COLONIES AND THE UNITED STATES IN THE 17TH AND 18TH CENTURIES.

Observer.	Locality.	Date.	Number of children to the married couple.	Number of marriages.
Engelmann. .	From genealogical records. . .	1600–1650	6.7	146
" . .	" " "	1650–1700	6.1	392
" . .	" " "	1700–1750	6.6	503
" . .	" " "	1750–1800	6.1	784
" . .	" " "	1800–1850	4.6	213
" . .	Portsmouth	1804–1811	4.27	
" . .	Hingham	1726–1779	4.32	521
" . .	Salem.	1727–1781	4.55	
Sadler.	United States	1750–1780	5.22	
"	New York State.	" "	5.22	
Holyoke. . . .	Hingham.	1782	4.5	Sickly year
" . . .	"	1783	4.6	Healthy year
Franklin. . . .	United States	. . . . .	8.0	Vague.

These facts very fully establish the low rate of fertility of the American woman at the beginning of the twentieth century. My genealogical records show that from 1600 to 1750, each marriage produced on the average at least 6 children, which, at the beginning of the nineteenth century, was reduced to 4.5, and these figures are corroborated from Salem by Dr. Holyoke, president of Harvard, and by Dr. Wigglesworth from Hingham, by a fertility of respectively 4.3 and 4.5 children to the marriage in the latter half of the eighteenth century.

Benjamin Franklin stated that "one and all considered, each married couple in this country produced 8 children." Whilst this is based upon no positive figures, the opinion of that great statesman is worthy of record, and it is to some extent corroborated when I state that the number of children given in my genealogical tables are only those who have reached maturity, so that the total number of children born must have been greater. Then again, it is well known that in the writings of Malthus, at the end of the last century, the great fecundity of the United States was used, together with that of China, as the basis for his theories of superfecundation, and in the table he gives the United States stands at the head of the list with a fecundity of 5.2, second only to New South Wales with 5.4 children to the marriage.

---

[3] My records clearly show that all the old obstetrical standards are in need of revision. The hitherto accepted standards as to sterility and miscarriage may never have been based on extended statistical investigation, may never have been precise, and at the present day, for this country, they are certainly far from the truth.

[4] The figures given by the writer are incomparable as being the number of children living, after a lapse of years. The number of children born living—the essential result—is not calculated, but proves to be 1.8.

Surprising as may be to us, with the figures of the present at hand, the fecundity of the American colonies of the eighteenth century, yet this is not excessive, as it is exceeded at the present day by the French-Canadian with a fecundity of 9.2 (facts based upon the study of 1000 families, kindly placed at my disposal by Dr. Pellitier, secretary of the Board of Health of the Province of Quebec, 9.3 for the rural and 9.0 for the urban population, but this is the fecundity of the child-bearing woman, not the number of children to the marriage). Then we must remember that at present in a Russian district it is 7.2, and in Norway 5.8 children to the family.

Divorce.—I mention divorce, as it is correlated with sterility and closely connected with the moral causes of childlessness. It has increased in frequency, particularly of late years, in Europe 67 per cent. from 1876 to 1886. and in the United States 72.5 per cent.

For the United States the census of 1890 shows 540 divorces to 100,000 married couples, which is approximated only in Switzerland by 195, in France 80, Germany 77, Russia in Europe 11, England 8.6 and Canada 1.6 to 100,000 marriages.

TABLE 4. DIVORCE.

Canada		1.6	63,000

In Rhode Island for 1898, if I may rely upon so able and accurate an observer as the Rev. Samuel W. Dike, it is one in every 8.2 marriages, which would mean 12,500 divorces to the 100,000 married couples, and for Massachusetts in the same year, 1 to 18.7; startling figures when we recall that in 1880 Rhode Island, by the United States census, is recorded with 1 to 190, and Massachusetts with 1 to 566.

Throughout the state of Ohio there is one divorce to 20 marriages, and in the Western Reserve, those counties settled almost altogether from Connecticut, the conditions are much the same as in the home state, 1 to 11.8; and in Lake and Ashtabula counties, settled by New England farmers, it is respectively 1 to 7.4 and 1 to 8.5. whilst in Callio county, settled by Welchmen and Southerners, it is only 1 to 50.

I myself have made no investigation whatsoever in this direction, but present the figures of Dr. Nathan Allen, figures originally collected by Rev. Samuel W. Dike and referred to in the paper of Dr. Allen, in which he shows the deterioration of the New England family; even if we disregarded these figures, correct though they be, and accept the figures of the United States census, it is apparent how much worse conditions in the United States are than in any European country.

The census corroborates in reference to divorce the relative condition which I have shown to exist in the matter of fecundity and miscarriage between the American of American parentage and the American of foreign parentage, with an average rate of divorce throughout the country of 0.54 *per cent. of all marriages;* among native Americans it is highest, 0.61 per cent., less among Americans of foreign parentage 0.5 per cent., still lower among foreigners, 0.3 per cent., and highest among negroes, 0.67 per cent., precisely the relation which these groups bear to each other in sterility and in an inverse ratio in fecundity.

The causes of the excessive increase of sterility and its concomitants are both moral and physical. Figures I have none, but all the facts point in this direction; so the frequency of relative sterility, the sterility which admits of conception but terminates in miscarriage, seems to me strong proof that causes other than uterine disease prevail; so also the fact that sterility is greater as luxury and comfort increases; that fecundity is less and miscarriage more frequent.

The causes of divorce we know to be purely moral, and the fact that the relative frequency of divorce, miscarriage, sterility and fecundity among the native American, the American of foreign parentage, the foreigner and the negro are so nearly parallel, would indicate that similar causes influence each; the prevailing causes must be the same, and these must be of a moral nature.

That barrenness, in the large majority of instances, is independent of physical causes, seems to be conclusively proven by the astonishing increase of sterility in this country coincident with the progress of gynecology, and with the same giant strides which have marked the development of the very science which should control sterility were it due to disease and physical causes.

All facts here presented indicate the prevalence of moral causes; moreover, the studies of Goodell, Nathan Allen, Charles Fayette Taylor and Edward J. Ill force upon us the belief in the frequency of methods for the prevention of conception, that "too often the young wife enters the sacred bonds with the distinct understanding that she desires no offspring, and does so because of the inconvenience it would give her." As methods of prevention are common so is the resulting barrenness, moral or wilful, so are intentional abortions frequent which lead to the same result; and for this fact, too, I rely on the statements of those who have studied the subject.

A committee appointed by the American Medical Association in vain sought methods by which to stay the progress of criminal abortion, which clearly indicates that there are causes for sterility altogether too frequent that are not referable to malformation or disease of the reproductive organs.

Treatment.—However numerous may be those who willingly avoid conception, and who by early indiscretions have brought upon themselves a sterility they now deplore, there is still a certain number absolutely, or primarily, sterile who seek relief, and these are women who deserve the deepest sympathy of the man and the best skill of the physician; for not one of the many ailments of woman is so distressing as the misery of a barren, childless life to the true womanly woman; she must never be condemned to a hopeless existence, and above all, no treatment of the woman for sterility must be inaugurated until we are thoroughly satisfied that the husband is not at fault, as proven by an examination of the semen.

Male sterility has been too much ignored, and is far more prevalent than is generally accepted. The studies of Gross have placed it as one in every six barren marriages, 16 per cent., and it has been variously estimated by those who have studied the subject from 3 to 57 per cent.

A valuable study by Brothers of New York, which has recently appeared, based upon an examination of 72 men, estimates 1 sterile man in every 5 childless marriages, but from his own figures, and in this he agrees with me, I am more inclined to place it as 1 in 4. Accepting this with the fact that impregnation is known to take place under the most adverse circumstances, as I have seen it after the removal of both ovaries; one tube totally and one in part, with but a shred of ovarian tissue remaining, as it has been found in the abdominal cavity through a slight fistulous aperture after the uterus had been removed (Koeberle); also after removal of both ovaries, with ovarian tissue from another woman transplanted upon the broad ligament (Robert J. Morris),[5] and after fixation of a bit of healthy ovarian tissue in the uterus (Palmer Dudley), it is evident that the condition must be serious which prevents impregnation.

Physical causes of sterility can not well be determined with certainty; first one, then another, has been supposed to be mainly at fault; uterine displacements have been accused; then uterine catarrh, and now we know that salpingitis is a frequent cause. Atresia, the absolute closing of the canals, gonorrhea and salpingitis I take to be the most frequent causes of sterility, and in addition, those forms of endometritis which change the secretions and render them destructive to the spermatozoa.

Treatment of physical causes only is within the province of the gynecologist, and this means a correction of the various pathological conditions which may exist; as we must always remember before inaugurating treatment to establish the potency of the husband, so we must bear in mind that frequently general conditions are at fault, such as anemia, depression, mental or physical; a change of surroundings and climate may bring relief, but whatever the cause, our efforts must never flag in behalf of these unfortunate women, as many cases are recorded where even after long years of sterility a cure has been accomplished and conception resulted.

Not only is the physician called upon to treat the absolutely and primarily sterile, but he is liable to be consulted by those who later in life relent of the nefarious practices of their early married years, and he is then confronted with the pathologic conditions produced by artificial sterility, nervous and physical, local and general, neurasthenia, prostration, impaired functional activity of circulatory and digestive apparatus, with pelvic congestion, uterine and ovarian symptoms.

These cases are tedious and trying, but it is the duty of the physician to persist, not alone for the sake of the innocent sufferer, but equally for her who, suffering from self-inflicted sterility and its sequences, has relented of her selfish life of egotism, and with the best instincts of woman aroused now longs for the joys of motherhood.

Whilst the moral phases of the question do not concern the physician, it is yet his duty to point out to his patient the causes of her sterility and her suffering, and the broadest field is here presented for preventive gynecology.

Two and five-tenths per cent. is probably the normal proportion of barren marriages, for this is the condition existing among the simple, healthy, hard-working people in Norway and in the interior of Russia, and a small percentage of this number is due to the male, not 25 per cent. as in civilized and infected communities; in this country nearly ten times this number of marriages are barren and women childless. This must be due, in a large measure, to methods of prevention, i. e., to artificial controllable causes. If these can be eradicated, preventive gynecology will have accomplished far more than can ever be hoped for from its most splendid therapeutic or surgical achievements.

RESUME.

This investigation is based upon numbers which, as I have emphasized, may seem small to admit of deductions as to conditions existing throughout a great country, but I feel justified in doing so, as the data are exact and cases carefully sifted. In addition, all the facts presented are corroborated in various ways; some directly by independent observers; first and foremost by the census records of two great states, namely, by the census of Michigan and that of Massachusetts; by the Boston dispensary and the records of the college alumnæ; others indirectly by correlated facts, a corresponding decrease of fecundity and increase of miscarriage and divorce. Table 5 forcibly presents the conditions with which we are now confronted in this country.

TABLE 5. MEANS AND EXTREMES OF STERILITY, FECUNDITY, MISCARRIAGE AND DIVORCE.

	Generally accepted average.	Most favorable condition now existing.	American Colonies, 18th century.	United States at the close of the 19th century.
Sterility . . . . Per cent. of childless marriages.	11%	2.5% Norway. . . .	2%	Gen. average. 20% 23% College graduates, 25%.
Fecundity. . . . . Number of children to the marriage.	4.5:1 Europe .	7.5:1 Canadian French. 7.2:1 Kaluga department. 6.4:1 Christiania.	4.5—6:1	1.8 College graduates, 1.6.
Miscarriage . . . . . . Ratio of abortion to full-term labors.	1:5.5	. . . .	. . . . .	1:2.8
Divorce. . . . . Ratio of divorce to marriage.	. . . . .	1:63,000 Canada. 1:11,000 England.	. . . .	1:185 United States. 1:18.7 Massachusetts 1:8.2 Rhode Island.

Sterility is fully 21 per cent. among the laboring class of St. Louis, 20 per cent. throughout the state of Massachusetts, 23 per cent. among the better situated in St. Louis, the same in the city of Boston among the laboring class even; it increases with the increase of comfort and luxury, highest among college graduates, 33 per cent. (or 25 per cent. if we take the total average), higher among American born than among foreigners in this country. Especially is the difference marked in that large and hitherto entirely ignored class of relatively sterile women, those who have conceived but who never have carried a child to full term, which is from 9 to 12 per cent. among Americans and from 3 to 6 per cent. among foreigners.

---

[5] For this I can not vouch: it is my recollection of a most remarkable case, but the authority is not in my hands.

Sterility has increased hand in hand with the much discussed decrease of fecundity; everywhere to some extent; in the United States it has increased to an excessive degree, just as fecundity has diminished more rapidly than in other countries. From a sterility of 2 per cent. in the eighteenth century, and a fecundity of five children to the marriage, conditions better than in any other country, and such as led to the Malthusian theory of super-fecundation, to the fear of over populating the earth's surface, after a lapse of one century, we have attained over 20 per cent., from first we have passed to last, and the other extreme is now presented—sterility greater and fecundity less than that of the women of any other nation, unless it be of France, where the question of the last decade has been one of most serious national importance.

These conditions, while not as yet menacing in any way the future of the country, as is at present the case in our sister republic, are sufficiently serious to indicate an imperative necessity for farther and more extended investigation.

DISCUSSION.

Dr. J. M. Duff, Pittsburg—From my experience during the past two years I feel that I am more than ever qualified to repeat what I said at Columbus, that we are fast becoming a nation of accidents. In investigating this subject I have been astonished when I come to talk with women and have accumulated evidence. The number of children who are the result of accident is enormous. It has certainly been the experience of every one in general practice to be called by a woman who will tell you that she is very sorry that this happened at this particular time because they were not ready or could not support a child. Of course, there are many fathers and mothers who are anxious to have children, and there are many more who say they are. They all believe in the sixteen-day story and as a result there are more children born conceived sixteen days after menstruation than at any other time. Fathers and mothers should be prepared physically and mentally for the production of their offspring, and there should not be accidental results. This question may appear trifling to some, but it is one of the most important and most serious questions before the American people to-day.

Dr. William H. Wathen, Louisville—We find that the prevention of conception is common throughout this country and is not regarded, by even the most religious people, as an evil; hence, few children are born to a family. Again, it is almost universally believed by the laity that there is no moral or religious wrong committed by performing an abortion up to a certain time. When there is a desire to produce an abortion, a means will always be found to accomplish this result, and unfortunately a physician, who is in good standing in the community in which he is living, will sometimes lend himself to that purpose. It is important to impress upon the laity that an abortion at the end of the first month is just as criminal as an abortion at the end of the fifth month, because if there is ever any spirituality in the child it must be at the beginning. Induced abortion is a moral, religious and physical evil. Induced abortions are followed by diseases much more severe than if they occurred naturally.

Dr. A. McDermid, Chicago—The field of operative obstetrics and gynecology is exceedingly attractive to all of us, but that a man should devote his time and attention to the subject in hand is beyond all praise. This work is of value not only to the profession, but to the laity and the state. I am proud of the statistics of my native country. I would ask you to take up the leading journals of the large cities of Canada and see whether you find in their advertising columns that class of advertisements which you find in the leading, respectable journals of the great cities of this country. In the matter of abortion, it occurs to me that the profession has a great work to perform in directing those who come under their care. I recall two instances of young married women who were both frantic when they found themselves pregnant shortly after marriage. By talking to them kindly and by showing them the terrible results following abortion, I succeeded in keeping them from doing anything rash. They are now enthusiastic over the prospect of maternity.

Dr. E. D. Ferguson, Troy, N. Y.—The essayist has put this subject forth in all prominence, but he has said nothing specific as to causation and nothing as to what can be done. National investigations may go on indefinitely; we may talk of the matter here, but there is no way of getting at it except through the 100,000 medical men of this country who will carry their own individual teaching into their own parochial work. The social conditions which have arisen during the century of our existence have made possible the thing which now exists. Our forefathers were not familiar with condums and other things resorted to for that worst of all vices, marital fornication. Neither were there in those days so many instances of double epididymitis. It is not the woman who is always at fault, nor is it a fact that women have graduated from schools of learning that has made them sterile. I do not believe that for one moment. It may be the case in statistics, but it is not in fact. Very likely a double epididymitis of the consort may have been the cause. Each one of you should consider himself a mentor and give out the warning words and point out the proper thing to be done. Every one of us can recall instances in which we have been confided in that the menstrual period had stopped soon after marriage and that we should do something to bring it about. We have then the golden opportunity, but only by our own efforts can we stem the tide of vile publications that appear as advertisements in our newspapers. It must be missionary work done by the physicians of this country and carried into the homes of their families.

Dr. M. F. Porter, Fort Wayne, Ind.—I agree with Dr. Ferguson when he says that it is not because these girls have graduated from Vassar that they are sterile, but that it is in large part the result of an epididymitis. Men contaminate their wives and make them sterile because, unfortunately, instead of becoming impotent they render their wives sterile through infection of the tubes. I believe that this is largely due to the current belief that an ordinary urethral infection in a young man amounts to nothing. Take gonorrhea out of this country and you have robbed the abdominal surgeons of their vocations. We should talk about the fitness of men with a chronic gonorrhea to marry, rather than the fitness of men who have syphilis. The syphilitic men are not killing our women, nor are they increasing the number of divorces; they are not depopulating our country nor making invalids of our daughters to one-half the extent that the men are doing who are the subjects of chronic gonorrhea.

Dr. George N. Jack, Depew, N. Y.—We ought to understand this subject better than we do. As a matter of fact our courses of education are not what they should be. We see evolution being taught in our schools, and we see religion in the decline. New principles are advancing to take the place of it. All people are sustained by a selfish purpose. It is my custom when patients come to me and tell me their troubles, to try and convince them that it is to their own selfish interest to bring forth children. I advance an argument, after which very few of them apply to me for assistance a second time. The matter is not so difficult of control if physicians will take the time and trouble to talk quietly and convincingly to their patients.

Dr. Hannah M. Graham, Indianapolis—The abuse of the physiological law of creation, as his statistics have well shown, weakens morality, murders the unborn, and makes physical wrecks of its followers. I recognize the fact that I am not a voter, but I speak to a body of men, each of whom enjoy the privilege of stamping the law with their individual approval or disapproval, and the question of who shall and who shall not marry has been discussed in our land until you are all familiar with the various objections given.

Dr. M. K. McCoy, Duluth, Minn.—I am very glad that the fault has not all been cast upon the women. However, the women of America have no encouragement to become mothers. What protection has she or her children? Confronting gonorrhea, the saloon on one side, the brothel on the other, and back of it all the abortionist, it is a wonder that any children are born. It is time that the protection of the family and the woman should be considered. The college graduates should not be held responsible for the decreasing family. In many instances these women also have dependent mothers, brothers and sisters, and they can not take upon themselves married life with its accompanying duties.

Dr. Englemann, in reply—It has been correctly stated that nothing was said in regard to the cause of these conditions. Neither did I say anything of the treatment; this was for want of time. The idea has been correctly expressed, as I myself put it, that the treatment is in the hands of every one of us; it is the influence the physician exerts, or should exert, in the home. I have endeavored to show that the causes of sterility and childlessness are moral causes. By far the largest percentage is statistically proven to be due to moral causes. Some few physical causes exist, such as atresia, endometritis, especially that due to a germ of some kind. However, they are not many. That endometritis is the cause of absolute sterility is shown by the breeder; abortion in animals occurs in some 12 per cent. of all cases; 5 per cent. in well-kept herds, but sometimes epidemics of abortion occur of such violence that the breeders speak of an abortion germ which is very likely nothing more than a streptococcus. It is an endometritis which leads to abortion in animals and at all the experiment stations antisepsis is now being practiced. They are guarding against abortion by antiseptic precautions. Inflammation of the mucous membranes is a common cause of sterility in the human being.

It has been rightly said that the male is at fault in a great many cases, but to arrive at a fair estimate of barrenness I believe that we may accept as a normal status in a healthy people the showing made in Russia and Norway where artificial means do not cause sterility, and there is childlessness in only 2 or 3 per cent., of which probably 5 per cent. is due to the male. That sterility of the male is far more common than is generally accepted has been shown in a very admirable manner by Dr. Brothers, of New York; it is so frequent that I must emphasize this precaution. Before treating the woman who comes to you because of sterility, examine carefully the male. It has also been rightly said that if the proper care were taken and an honest course pursued, there would be very little gynecology. The proper advising and guiding of these mothers in health will do more to help women than all gynecology and surgery. Sterility has gone from worse to worse in the face of gynecologic progress. To this astonishing fact I neglected to call your attention, and you may well ponder on the increase of sterility in the face of progress and development of gynecology, showing that sterility has practically nothing to do with physical causes. There are few physical causes; the main causes are moral; therefore, the treatment does not fall strictly within the sphere of the gynecologist. You may rightly ask why I bring this matter before this Section; it is because I do not know where to place it, and in a measure it is gynecological because it deals with pathological conditions of women.

Conception takes place so easily and under the most adverse circumstances that the physical causes which prevent conception must be serious indeed. Women will conceive when there is only a bit of ovarian tissue left, even when the uterus is removed, as in the case of Koeberle; impregnation took place and the ovum developed in the abdomen.

The interesting remarks of Dr. Duff are in the line which must be followed. He clearly pointed out the efforts made to prevent conception with that sixteen-day story, and it would be well to bring prominently before the profession the fact he imparts, i. e., that the mass of children are conceived after that time—after the sixteen days from the cessation of the menses. It is true that the majority of conceptions are mistakes. This is an important subject, for the lack of fertility has invariably been the precursor of national decline.

THE MORTALITY OF APPENDICITIS.*

JOHN B. DEAVER, M.D., and GEORGE G. ROSS, M.D.
PHILADELPHIA.

During the year 1900 there were operated upon at the German Hospital, Philadelphia, 268 cases of appendicitis, of which number 144 were acute attacks of the disease and 124 were chronic. Of those operated upon during the acute stage of the disease, 26, or 17.8 per cent., died, either from the disease or from some intercurrent trouble arising during the illness, or, existing prior to the time of operation. One of the patients who had diabetes mellitus, and in whom the existing abscess was simply drained under local anesthesia, died of diabetic coma three days after operation. Another case had advanced phthisis at the time of the operation and died of peritonitis. Still another case developed a post-operative pneumonia, from which he died on the second day following operation. If we deduct these three cases, the mortality of this series of cases is 15.9 per cent. for acute appendicitis without intercurrent disease.

In the 26 fatal cases the following conditions were noted:

Seven cases had general purulent peritonitis at the time of operation. In 7 others a general purulent peritonitis occurred subsequent to operation; in 8 cases septicemia was the cause of death; 1 case died of shock, and 1 died of shock following a second operation for the relief of an intestinal obstruction due to bands of adhesions. The remaining 2 were the cases of phthisis and diabetes referred to above.

In the 7 cases of post-operative peritonitis the appendix was removed in every instance. In 3 of the cases the appendix was post-cecal, and, by its removal, an unsuspected collection of pus was discovered. In 1 other the appendix occupied the center of a collection of pus and was complicated by a gangrenous cecum. In another the appendix was behind and to the outer side of the cecum, and lay in a mass of infected exudate, and there was also an abscess in the muscular layers of the abdominal walls. In the sixth case an abscess was encountered immediately on opening the abdomen, the contents of which escaped, both externally and into the general peritoneal cavity, before anything could be done to arrest it. In the seventh case the appendix lay to the cecal side of the abscess wall and was not a portion of it. This was the phthisical case, and death was due to septic peritonitis.

The time which had elapsed between the onset of attack and the time of operation was as follows: In 7 cases with purulent peritonitis at time of operation, in Case 1, it was less than 12 hours; in Case 7, 20 hours; in Case 18, 24 hours; in Case 15, 2½ days; in Case 5, 3 days, in Case 9, 10 days; in Case 16, 21 days.

In 7 cases of post-operative peritonitis it appeared as follows: Case 21, 24 hours; Case 13, 5 days; Case 20, 7 days; Case 25, 8 days; Case 8, 14 days; Case 27, 50 days; Case 10, not noted.

In 8 cases of septicemia it was as follows: Case 12, 2 days; Case 2, 2 days; Case 9, 7 days; Case 23, 10 days; Case 19, 10 days; Case 4, 14 days; Case 3, 17 days, and Case 22, 49 days.

Shock was observed in Case 17. There was no history, but there was found an intraligamentary cyst, cystic ovaries and numerous inflammatory cysts. Intestinal obstruction occurred in Case 24 in 24 hours.

As regards the number of attacks, they were as follows: It was the first attack in 13 cases; the second attack in 5 cases; fourth in 2 cases; sixth in 1 case, and it was not noted in 6 cases.

The character and severity of the attack was shown, with classical symptoms, to be severe in 20 cases, and with classical symptoms, to be mild in 6. It was not noted in 1.

The position of the appendix and its relation to other organs was as follows: Post-cecal, in 12 cases; in or toward pelvis, 12; toward spleen, 1; not noted in 1, and not looked for in 1.

The complicating diseases were: Diabetes, 1 case; phthisis, 1; pneumonia, 1; ovarian cyst, 1, and intraligamentary cyst, 1. Nearly every case showed evidence of nephritis after operation, except the case operated under local anesthesia.

The extent of the inflammatory process in appendix was as follows: Intense inflammation in 7 cases; gangrenous in 10; perforation in 3; gangrene and perforation in 5; chronic inflammation in 1, and not sought for in 1.

Secondary collections of pus were encountered in 11 cases; 7 in the pelvis, 3 post-cecal, 1 to the median-line side of right iliac fossa, and 1 in the abdominal walls.

Gangrene of the cecum and colon was encountered in 7 cases. In 5 it existed at the time of operation, and in 2 cases it developed subsequently. It is probable, however, that the damage to the bowel had occurred before the abdomen was opened.

The one death in chronic appendicitis was in a case where an ovarian cyst, which was adherent to the appendix, complicated the appendiceal operation. In addition to the ovarian cyst there were numerous inflammatory cysts. The patient did well until the third day, when the drainage tube was removed, after which she promptly developed a septic peritonitis and died on the sixth day following the operation. Whether the sepsis was introduced from without at this time or whether a latent sepsis in the peritoneal cavity was liberated by the manipulation is a matter of surmise. Yet it is the opinion of the authors that this was a case of post-operative infection.

The fatal cases of appendicitis that I have reported do not by any means cover the subject of the mortality of appendicitis. In consequence of this I will digress a little from these cases for a short discussion of the

MORTALITY IN GENERAL.

In the cases not subjected to surgical treatment, by far the largest factor is septic peritonitis. This arises in one of several ways: 1, transmigration of micro-organisms from an ulcerative or interstitial appendicitis, without rupture of the appendix; 2, gangrenous appendicitis or rupture of the appendix by ulceration, without peritoneal adhesions localizing the septic area, and 3, internal rupture of a peri-appendiceal abscess.

Another quite common termination is an obstruction of the bowel, either by adhesions of the appendix to neighboring small intestines, or by the bands of adhesions thrown out in nature's efforts to localize a septic area.

The factors mentioned above are responsible for by far the greater number of deaths in non-operative cases of appendicitis. Yet there are other complications that are seen quite frequently, for instance, the deposit of septic material in distant parts of the body, as the liver, lungs, brain, heart, etc.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: W. J. Mayo, H. O Walker, and A. J. Ochsner.

Rarely an abscess rupturing into the bladder will causes a fatal cystitis or pyelitis. In regard to the number of attacks, it is to be remembered that the fatal attack may be the solitary severe one, and during it the proper diagnosis is made for the first time. Severe attacks without fatal issue subside to varying degrees, but commonly render the internal symptoms more aggravated.

As we are firm believers in the operative treatment of this affection, our main interest is in the causes of a fatal termination in those cases submitted to surgical treatment. In cases of chronic appendicitis without adhesions, or in acute cases operated during the attack in which the lesions do not spread beyond the peritoneal coat of the appendix, the mortality is confined entirely to those causes that are inseparable from any celiotomy. Septic peritonitis due to errors of aseptic technique, hemorrhage from the slipping of ligatures, nephritis and pneumonia coming on during convalescence, and the unavoidable dangers of anesthesia.

In those cases complicated with adhesions, but without septic infections, the mortality is also very low, yet there are certain operative factors that greatly increase the mortality in these cases over the class just described. The necessity of a large incision, greater liability to hemorrhage from the adhesions, and the danger of tearing the peritoneal coat from the bowel in freeing adhesions, which latter accident is very likely to result in a fatal necrosis of the bowel, all add to the gravity of the operation. In addition, in a certain proportion of these cases, gauze must be packed into the bed of the appendix to control hemorrhage not accessible to ligature, thus adding to the case the dangers connected with gauze drainage. The principal dangers are, infection from without carried to the peritoneal cavity along the gauze, and obstruction of the bowels, either by the disposition of the gauze, or by the adhesions necessarily remaining after its removal.

In the series of cases reported, there is one death belonging to this class of cases. This case was complicated with an ovarian cyst and has been discussed above.

The two classes of cases described above comprise those in which the operation of election was done, and in which the mortality is very low. Of these cases, 124 were operated upon at the German Hospital in 1900, with only one death, or 8 per cent. Contrasting this record with those operated upon in the presence of pus or gangrene, of which there were 144, with 26 deaths, the grounds for my belief in the early operation are clearly seen.

There is one class of cases of appendicitis, however, in which, in the great majority, a lethal termination is reached in spite of any plan of treatment. These cases can be appropriately called fulminating. Several of the fatal cases reported illustrate this type. In them, operation even in the first hours, is too often unavailing, as the first symptoms are those of general purulent peritonitis. In one case of this series, I operated twelve hours after the onset of the attack and found an advanced general purulent peritonitis, a condition from which I have never seen a recovery.

Many cases are reported in the literature as recoveries from general purulent peritonitis, but from my experience I am led to think that there was probably some error in the diagnosis, and that the cases were probably a very extensive, but nevertheless localized peritonitis. In cases in which the first attack is of this type, it is hard to see how a fatal termination can be avoided, but if there have been other attacks previous to the fulminating one, some one is responsible.

In cases of appendicitis with localized collections of pus, the success of the operation to a great measure depends on our success in emptying and thoroughly draining every pocket of pus. Merely opening and draining the main abscess will not do, for there are frequently secondary collections of pus in the pelvis, or among the small bowels, which, if left unevacuated, will render our operation unavailing. The great problem in this operation is how to drain all these collections without infecting the general peritoneal cavity. Irrigation is a frequent cause of this and should only be used with the greatest caution.

Of the four main localities of appendiceal abscesses, that situated to the outside of the cecum gives, perhaps, the most favorable prognosis, as we can keep to the outer side of the general peritoneal cavity, and, by a counter opening in the loin space, secure free drainage. The next most favorable variety is that situated anterior to the cecum and directly under the abdominal wall. Next in order comes collections of pus in the pelvis, and then, most dangerous of all, local collections, one to the median line side whose walls are made up principally by small intestines. Post-cecal collections of pus offer a serious problem to the operator, for it is in this locality that we have post-peritoneal infection and necrosis of the bowel. If the pus be not localized, but free in the peritoneal cavity, there is no hope of recovery, unless perhaps by operation in the first hour or two, when only the serum is infected and peritonitis has not actually begun. The reason for the varying degrees of danger in the different varieties of appendiceal abscesses, lies in their adaptability to evacuation without contamination of the general peritoneal cavity.

The advisability of removing the appendix in the presence of pus has been the subject of much discussion. In the opinion of the author the appendix should be removed except under very exceptional circumstances, for by so doing we render less likely the following possibilities, which are active factors in appendiceal mortality: Fecal fistula; an undiscovered secondary collection of pus; subsequent attacks of the disease, and the danger of subsequent necrosis and obstruction of the bowel. With these objects to be attained and with the surety of freedom from spread of infection by the use of a proper technique, it seems advisable to remove the organ. There are, however, a few cases in which from the depressed condition of the patient we must be content with draining the abscess, leaving the removal of the appendix to a subsequent operation.

Another very common cause of death in these cases is necrosis of the bowel, probably due to septic emboli in the veins of the mesentery, or pressure from the plastic exudates. Metastatic abscesses, septic endocarditis and obstruction of the bowel also account for the death of some of these cases.

Ether for some unexplained reason is especially badly borne by these patients and adds greatly to the anxiety of the operator.

In the 118 cases operated upon during the acute stage of the disease and followed by recovery, it is interesting to note the following facts: In 61 cases pus was present. Of this number, the appendix was perforated and gangrenous in 21 cases; 2 cases had perforation without gangrene; in 25 cases, infection occurred by migration of micro-organisms through the walls of the appendix, and in 13 cases the records fail to show the condition of the appendix. In the remaining 57 cases, the inflammation was confined to the appendix. In 6 cases there occurred fecal fistulæ, 4 of which closed spontaneously, 2 requiring a subsequent operation. There were 56 cases operated upon in the first attack, and in the remaining 62 cases there was an average of 4 attacks.

During the year there were in the hospital 11 cases of acute appendicitis that were not operated upon, 3 of these died. Of the remaining 8, who refused operation, 5 left with a mass in the right iliac fossa, and in 3 the lesions were apparently confined to the appendix.

One thing seems certain, one attack predisposes to other attacks, and, barring the rare cases of obliterating appendicitis, each attack renders the operation more difficult on account of adhesions, *their multiplication and* tendency to denseness and contraction, thus detracting from a favorable prognosis. It is very common, however, to elicit by careful questioning a history of attacks of abdominal pain, which at the time of their occurrence were ascribed to other causes, e. g., bellyache, cholera morbus, "bilious attacks," typhoid fever, cholecystitis, nephritic colic, neuralgia of the stomach or bowel, or to entero-colitis, hepatic colic, etc. In giving a prognosis the possibilities of these being appendiceal in origin *must be taken into consideration.*

The character and severity of attacks is of great moment and must be duly considered in the question of appendiceal mortality. Certain cases begin with an attack, which, from its incipiency, is of the greatest severity, both as to symptoms and pathologic changes as well. These cases are known as the fulminating variety, and the destructive changes in the appendix take place in a few hours. I have operated within twelve hours after the onset of the first attack and have found a gangrenous and perforated appendix, with abscess and gangrene of the cecum, *as shown by Case 1.*

In another patient, Case 21, operated upon within twenty-four hours after the onset of the sixth attack, we found the appendix gangrenous, perforated and bound up in a mass of dense adhesions which involved the cecum, small intestine and parietal peritoneum. This patient died of general purulent peritonitis sixty hours after operation.

In still another, Case 7, which was operated upon twenty hours after the onset, we found a gangrenous, perforated appendix with forming adhesions and general purulent *peritonitis. Here nature was attempting* to protect the peritoneum, but was too slow to encompass the ravages of the diseased process in the appendix.

I might go on and report many cases of this frightfully-rapid type of the disease, where even the earliest operative procedure may be of little avail. Where this has occurred in the first recognized attack, it is difficult to see how matters can be mended, but where it arises in an attack after the original one, some one is at fault, for many such deaths could have been prevented by operation at an expedient time.

In most fatal cases which can not be classed as fulminating, the attacks are of varying severity, although many of them are severe and progressive. However, one must be on the watch for those cases, mild as far as symptoms indicate, but in which, nevertheless, the pathologic changes are progressively destructive. Such a case was found in A. H., who was operated on in the second week of her first attack. The appendix was gangrenous, and, together with the cecum and small intestine, formed the abscess cavity wall. In this case the pelvis was full of pus, and she died of septic peritonitis.

It has been my experience that recurrent attacks of appendicitis are generally progressive in severity, each one adding fuel to the flame. Adhesions grow more numerous and dense. The blood supply of the adherent organs becomes altered. Post-operative necrosis is rendered more probable, and the stripping off of the peritoneal coat of the cecum or bowel is aided, thus favoring post-operative necrosis of the intestine.

POSITION OF APPENDIX.

Its position and relation to other intra-abdominal organs, as illustrated in this series of cases, is as follows: In 12 cases the appendix was found behind the cecum; in 12 others it occupied a position pointing toward the pelvis; in 1 toward the spleen; in 1 the position was not noted, and in the other the organ was not looked for. This series would seem to point to an equal division of severity so far as the position goes, but nevertheless an appendix pointing toward the pelvis is rather more favorably located than one behind the cecum.

The position of the appendix is of the utmost importance in a conideration of the subject before us. An appendix which *occupies a position behind the cecum.* pointing upward toward the liver, is a favorable locality for fatal attacks of appendicitis. An acute inflammation of an appendix in this position favors post-peritoneal infection, either by the route of the lymphatic or venous circulation. Collections of pus dissect up the posterior layer of the peritoneum; by the burrowing pus, the blood supply of the cecum is interfered with, and necrosis of the gut is apt to follow. This location of a septic collection favors abscess of the liver, a condition, however, which is rarely met with as a complication of appendicitis. Then, too, in this class of cases septicemiæ plays an important rôle.

The appendix, holding a position in the pelvis or in the direction of the pelvis, offers a slightly better prog*nosis than when it is behind the cecum.* This is, however, far from being a favorable locality; for in a fair percentage of the fatal cases the appendix occupies this position and the pelvis contains a large amount of pus.

In the female, a collection of pus in the pelvis is not only unfavorable to the life of the patient, but the disastrous effects upon the uterine adnexa are marked even in those cases which recover, and such patients are condemned to lives of invalidism. Pyosalpinx, uterine and bladder adhesion, and adhesions between the uterus and sigmoid or rectum, are common events in this class of cases.

In the male a sloughing of the pelvic fascia is not uncommonly met with, and is a condition of great seriousness, not only as to life, but also as to the health of *the patient who does not succumb* in the acute stage of the disease.

In connection with the subject of the locality of the appendix, a point which has been very forcibly brought to my notice is the frequency with which collections of pus have been found in the pelvis. I make it a routine practice to pass a glass drainage tube into the pelvis in every acute case of appendicitis, and have with astonishing frequency discovered pus.

When the appendix points toward the spleen, general peritonitis is of common occurrence, and this position must therefore be considered a dangerous one. It is with this direction of the appendix that secondary abscesses occupying an area to the median line side of the right iliac fossa so commonly occur and are frequently overlooked. Other positions, such as in the ileo-cecal, ileo-colic or sub-cecal fossa, are associated with destructive phenomena.

DISEASES COMPLICATING.

Diabetes as an associated trouble enters into the consideration of our subject, for recently I had a case of an acute attack where the abscess was opened under local anesthesia, but the patient succumbed to diabetic coma.

Nephritis is far more common, and its relationship and true value as a factor is not as entirely established as one would wish or could expect. Nearly all my cases, both the fatal ones and those which recover, show albumin and hyaline and granular casts after operation. Is this due to the ether? In those which recover, the symptoms of the nephritis gradually subside without any evidence of permanent injury to the kidneys. It does seem probable, however, that, other things duly considered, in the fatal cases the nephritic condition must play an important part in lowering the patient's resistance by the retention of constitutional poisons and the alteration of the blood pressure.

A septic condition of the heart and its membranes is a serious complication and is invariably fatal. Endocarditis is not uncommon, and although the fatal issue may be deferred, it is none the less sure. The same can be said of myocarditis and pericarditis.

Septic pneumonias are common, but not necessarily fatal, as a fair percentage of these cases do get well. It is, however, a serious matter, and may determine the end.

Appendicitis in a phthisical patient offers a problem which is difficult of solution. I operate on them when pus is present, but only as a last resource, and then do as little surgery as will meet the indications.

Infection of the appendix by the typhoid bacillus is far more common than is usually accepted by our medical brothers. The active stage of the enteric fever does not, *per se,* offer a contra-indication to operation in the presence of acute suppurative appendiceal disease. I have on several occasions operated under these circumstances with a happy result.

TIME BETWEEN ONSET AND OPERATION.

This brings up the often-debated point as to the time for operation, and I would like to state here, with all the emphasis at my command, that delay in operation is responsible for more deaths in appendicitis than are all the other factors which have to do with the disease. Barring some cases of the fulminating variety, where nothing that man can do avails, there are no cases which, if operated upon within the early hours (preferably the first 12 hours, and at the latest 18 to 24 hours), that can not be saved, not only to live useful lives, but to live them minus fecal fistulæ, tugging adhesions, danger of intestinal obstruction, and chronic or subchronic invalidism. Also allow me to emphasize the ever-increasing difficulties of operation with a directly corresponding decrease of a favorable prognosis, which attends each succeeding attack of appendicitis. I am sure that those of you who are constantly seeing and meeting this disease in its various phases will agree that early operation stands without a peer as the method of choice.

EXTENT OF INFLAMMATION.

The various degrees of inflammation are all attended with a mortality; the acute catarrhal being the lowest in the scale. Interstitial appendicitis is very commonly attended with peri-appendicular infection from migration of organisms through the diseased walls, and has a higher percentage of mortality than the catarrhal. Gangrenous and perforative conditions, which can be properly classed together, are attended with the largest death rate of all varieties of appendicitis. There we have a direct outpouring of the highly septic contents of the organ into the surrounding tissues, which, from the inflammatory process set up by nature to protect it against the coming invasion, has become a fertile soil for the growth of the infecting organisms.

The location of the perforation and the relation it bears to surrounding tissues and organs is a very important point. An appendix pointing into the pelvis which perforates at its tip will offer a better chance for localization of the subsequent abscess to the pelvis and insure a better prognosis than if the perforation takes place at or near the proximal end, for here the chances of general peritoneal infection are increased.

An appendix situated behind the cecum, pointing toward the liver, will be followed by serious results, no matter where the perforation occurs, although a perforation at the distal end will increase the danger on account of the proximity of the liver and kidney. A perforation at the base of an appendix located behind the cecum, and particularly if it be on the posterior wall, will favor retroperitoneal infection.

It may be laid down as an axiom that the danger of death in acute appendicitis increases in direct ratio to the area of peritoneum involved in the septic process.

When the process is limited to the right iliac fossa, the lowest percentage of mortality is accomplished with the spread of the septic process to the pelvis, and thence becoming diffused, we have an ever-increasing fatality until we arrive at the infection of the general peritoneum, when the apex of the scale of mortality is reached. I can say truthfully that I have never seen a patient recover in which the general peritoneal cavity was infected throughout its entirety.

With all due deference to my professional brethren who report cures of general septic peritonitis, I must nevertheless say that their cases were extensive, no doubt, but just as surely were they cases of localized infection in which there remained some healthy, uninfected peritoneum.

ANESTHESIA.

This plays but a minor part in the mortality of the cases upon which this paper is based. Ether is used almost invariably and we have had but few accidents, and rarely a death which could be ascribed to the anesthetic. We have used spinal cocainization, but do not see that it offers any advantages or decreased risks over ether narcosis and it has certain decided objections. It does not secure muscular relaxation and therefore interferes with the operator and increases the risk of infection by the forcing of a knuckle of gut into the area of infection.

Occasionally a patient will inspire mucus, calling for tracheotomy, and this may be followed by an inspiration pneumonia. These accidents are to be laid to the condition of the patient rather than to the anesthetic. A patient with a septic condition in his abdomen will frequently take ether very badly and have respiratory failure or clogging of the trachea and larynx with mucus.

DIFFICULT CONDITIONS.

The position of the appendix, as has been said, in its relationship to contiguous organs, influences the difficulties of operation and the prognosis. It is far more difficult to remove an appendix which forms part of the wall of the abscess cavity or infected area, or one which is behind the cecum, than one which springs into view as soon as the peritoneum is opened, and undoubtedly the removal of an appendix under such circumstances increases the risk unless it is performed by one whose technique is highly developed, and who fully realizes the dangers to the patient. I believe, and to my own satisfaction have demonstrated, that the removal of the appendix, except in rare instances, will give the lowest percentage of mortality.

Adhesions always mean increased operative difficulties and both directly and indirectly are responsible for appendiceal mortality. Directly, by the danger of desseminating infection, by the concealment of secondary collections of pus, and by hemorrhage; and indirectly, by intestinal obstruction, by stripping off of the serous coat of the bowel and subsequent necrosis, and by tearing the mesentery with the same result. And yet adhesions are of use to those unfortunates who are denied, by their own or their physician's prejudices, the benefits of early operation. The post-operative pains of patients who have had abdominal adhesions are so common that one dreads to meet with them at the time of operation. The pain is due to tugging and pressure on the adherent organs.

Perforation of the appendix is not necessarily a fatal accident, yet it is of common occurrence in fatal cases. As has been said, the danger of perforation lies in the locality of the perforation and its relation to the position of the appendix. When perforation occurs in the early hours of an attack, before the confining wall of lymph has become sufficiently organized to protect the peritoneum, the danger of a fatal peritonitis is increased. Perforation is always indicative of an extensive pathologic change, those leading to the rupture and those which follow as a result of the free outflow of infectious material. What has been said of the perforative type is to a great extent true of the gangrenous, for the two are usually found to co-exist. It is in these two varieties that the secondary septic complications arise that are responsible for so many deaths.

There are the following five varieties of appendiceal abscess dependent upon the location of the collection:

1. This is the most common in my experience, and is the one in which the collection is located post-cecal, or between the layers of the ascending meso-colon. This variety is attended by a high rate of mortality. Here it is that we find post-peritoneal infection, lymphadenitis, phlebitis and pyelo-phlebitis. I have come to dread the consequences of this last variety of abscess on account of the tendency to gangrene of the cecum and colon, as a result of the disturbance of the circulation of the bowel by the dissecting process of the pus, to pressure necrosis and to septic thrombosis of the mesenteric arteries. This has occurred in a large percentage of my fatal cases of post-cecal abscess. The gangrenous condition of the bowel may occur prior to and subsequent to the time of operation, coming on as late as two or four days after operation; and when it does occur is apt to be rapidly fatal.

2. This variety is that in which the collection is immediately beneath the parietal peritoneum, being confined by the cecum, coils of small intestine, the omentum, the appendix, parietal peritoneum and masses of inflammatory lymph. In this variety the mortality is much lower than in the previous one, for the general peritoneum and lymph channels are shut off from infection. It is here that the question of the removal of the appendix comes up. Every case must be judged by itself, and a procedure decided upon which will best suit the case in point. However, in the vast majority of these cases the appendix can be and should be removed. Simply draining the abscess will allow your patient to recover from that particular attack, but does not offer a cure of the disease, for the likelihood of recurrence is not removed, and with each subsequent return the difficulties of operation and the dangers of an unsuccessful termination are distinctly increased.

In the cases of several of my patients who died of peritonitis subsequent to removal of the appendix, under the above-mentioned circumstances, the infection may have occurred as a result of this procedure. Nevertheless, more cases will get permanently well by removal of the appendix than would do so by allowing the gangrenous and perforated mass to remain.

3. In this variety the collection occupies the pelvis, and it is very common. It is, however, frequently unsuspected and undiscovered. Of all the varieties of appendiceal abscess, this is the most favorable for recovery, although it is frequently attended by involvement of the pelvic organs, especially in the female. The favorable prognosis of this variety is due to the isolation of the pus, owing to the dependent position of the pelvic collection.

4. This variety in which the collection is located near the median line of the abdomen and to the median line of the cecum renders a fatal issue exceedingly likely. It is this variety that is most apt to be associated with secondary collections. The difficulty of treating such an abscess, without infecting the general peritoneum, is extreme and frequently impossible.

5. Here the collection is free in the general peritoneal cavity, and in this variety the cases are practically all fatal unless operated upon very early.

Case. 1.—W. C., aged 21 years, single; American; machinist. Admitted July 4, 1900.

Not feeling well for two days before admission. Complained of diarrhea and slight pain in abdomen. Twelve hours before admission was taken suddenly ill with severe pains in abdomen, vomiting several times. On admission abdomen distended, tympanitic and exquisitely tender. No movement of bowels or passage of flatus for 12 hours. Pulse wiry, rapid.

Operation immediately after admission: incision about four inches long, through right rectus muscle; as soon as the peritoneum was opened a large quantity of cloudy, brownish fluid escaped; intestines were red, injected, lusterless, and covered in places with a grayish-white exudate, as was cecum around the attachment of appendix. Appendix was ligated and cut off. Pelvis was drained with a glass tube, and one piece of iodoform gauze. Incision closed with silkworm-gut sutures.

Died 36 hours after operation, with symptoms of general peritonitis.

Urine after operation was scanty, albuminous and contained hyaline and granular casts.

This case belongs to the fulminating class in which operation must be performed in the first hours of the attack if the life is to be saved, for although the patient was operated upon within 12 hours from the beginning of the attack, the pathologic conditions found at operation would make recovery very exceptional.

Case 2.—W. C., aged 32 years; married; American; machinist. Admitted to German Hospital Nov. 1, 1900, and the following history was obtained:

His father died of old age; mother living and well; 1 brother died of an accident, and 1 sister died in infancy; 3 brothers are living and well. Has used tobacco and malt liquors habitually. Denies venereal diseases. He had measles in childhood, but has been in good health since then. He had a slight attack of abdominal pain two weeks ago, but no other history of appendicitis. His present condition began two days ago. The onset was sudden, with pain in right side of abdomen and tenderness. Bowels were regular before attack; during attack he took castor oil, from which he had two or three bowel movements. The pain was cramp-like, and became steadily worse hour by hour. He had no digestive disturbances; there was rigidity of the right rectus muscle, but no distension.

Operation one hour after admission. Ether was used, which he took badly, becoming markedly cyanosed, with dilated pupils and rapid pulse, while his abdominal walls were not relaxed. An incision five inches long was made through the right rectus muscle. The omentum was red, inflamed and adherent to the intestines. The appendix and bowel around it were densely adherent; appendix was behind the cecum, gangrenous and adherent, and surrounded by a collection of pus. Appendix was freed and removed and cavity drained. Wound partly closed with through-and-through sutures of silkworm gut.

Nov. 4, 1900. Abdomen is flat; passes flatus; stomach retentive; is extremely restless and can not sleep. Has an anxious expression; cold, clammy hands; leaky skin; rapid weak pulse. He is mentally clear. Died at 8 p. m.

Partial postmortem through incision showed partially gangrenous condition of colon, and cecum with a plastic peritonitis; right-sided chronic pleurisy; a severe parenchymatous nephritis.

In this case, as in the previous one, earlier operation was almost essential to a favorable outcome. From the conditions found, there must have been previous attacks, as the adhesions were too dense to have formed entirely in two days. Another of the disadvantages of late operation was here shown, in the large amount of ether he required and a subsequent ether nephritis.

Death was directly due to a septic absorption from a gangrenous bowel, caused either by pressure of exudate, or more likely septic thrombus in the mesenteric vessels. This is probably a commoner cause of death in cases like this than is general septic peritonitis.

Case 3.—H. L., aged 45 years; married; Irish. Was admitted to German Hospital, Jan. 12, 1900, with the following history:

Parents died of old age; does not remember having any of the diseases of childhood; was never sick until present time; smokes moderately; denies venereal disease.

Was first taken sick on Christmas day, 1899, with pain in the right iliac region. The pain came on suddenly and was associated with tenderness and constipation, but no vomiting. Does not think anything that he ate caused the trouble. Has been subject to bellyache for two years, but has had no attacks as severe as the present one. The pain has persisted ever since it began, being a little better for a day or so, and then again worse.

On admission, has pain and tenderness in right iliac region; there is rigidity of right rectus. Blood count: Hemoglobin, 75 per cent.; 4,550,000 reds and 16,000 whites.

Operation, Jan. 18, 1900. The patient was etherized and a long incision made through the rectus muscle. The cecum and appendix were bound down by dense adhesions; when the bowel was finally freed, it was bleeding from numerous points.

An attempt was made to cover the bleeding points with folds from the contiguous peritoneal coat of the cecum. In doing this it was found that the serous coat of the bowel was soft and friable. The appendix was cut out of the cecum, and the wound closed with Lembert sutures. Two large pieces of iodoform gauze were left in for drainage, and the wound partially closed.

Patient died five days after operation, with symptoms pointing to septic absorption from gangrenous bowel, although no postmortem examination was made.

This case was probably one of subacute appendix of two years' standing, and ought to have been operated upon long before.

Case 4.—A. H., aged 18 years, single. Admitted May 13, 1900, to German Hospital, with the following history:

Parents are in good health; 2 brothers died in childhood; 2 brothers and 3 sisters living and well. Except for the diseases of childhood has always been well. Menstruation normal, began at 16 years.

Present illness began two weeks ago with a sharp pain in the right side, accompanied by tenderness and vomiting. The pain continued three days, then gradually subsided, only to return in two days, and was again associated with vomiting. Yesterday—May 12—was the last attack of sharp pain; it lasted several hours, during which she vomited twice.

On admission there is no pain, no tenderness, no rigidity, no nausea or vomiting. No mass palpable through the abdominal wall, but a distinct mass, tender to the touch, is felt through the rectum.

Operation, May 14, 1900; Incision made through the right rectus. The cecum and coils of small bowel in the right iliac fossa were adherent, and when separated a small abscess behind the cecum was ruptured liberating about 50 c.c. of offensive pus. Gauze had been packed about the region to wall off the general peritoneal cavity. The appendix was part of the wall of the abscess referred to, and as it was not sufficient to account for the mass felt in the pelvis per rectum, the pelvis was explored, and an abscess was found containing about 160 c.c. of very malodorous pus. This was evacuated, and a glass drainage tube was inserted. A counter opening was made in the flank, and rubber drainage introduced. One piece of gauze was lightly packed about the rubber tube, to control some bleeding, and two pieces of gauze were placed about the glass drainage. The wound was partially closed with through-and-through sutures.

May 15. Fecal material is coming through the glass drainage. Glass drainage tube removed.

Patient died on the seventh day, May 21, with symptoms of general sepsis.

Urine albuminous with hyaline and granular casts.

This case illustrates what serious conditions may be present, and yet show very few symptoms. Of course, operation should have been done two weeks earlier.

Case 5.—R. J., aged 14, single, schoolboy. Admitted May 19, 1900, and the following history obtained:

Has been sick for three days. The attack came on suddenly with severe pains in abdomen, nausea and vomiting. On admission abdomen distended and painful to touch. Operation as soon as admitted.

An incision was made through the right rectus muscle. On opening the peritoneum a large quantity of yellowish fluid containing white flakes escaped. The appendix was found in the pelvis, surrounded by a large quantity of very offensive pus. The appendix was ligated and excised. Glass drainage tube placed in pelvis. The general abdominal cavity was then thoroughly washed with saline solution. Iodoform gauze placed in for drainage. Part of incision closed with silkworm-gut.

The patient died two days later of general purulent peritonitis.

Case 6.—S. J. N.. Acute appendicitis. Admitted May 28, 1900.

Was sick for ten days before admission; complained of nausea, constipation, pains in abdomen, and tenderness in right side. Two days before admission symptoms became severe.

On admission: Abdomen distended, tympanitic and very painful. Pulse rapid and wiry.

Operation: Incision about 6 inches long made through right rectus muscle. On opening peritoneum about one gallon of cloudy, yellowish serum escaped. Intestines red, covered with exudate, lusterless. The appendix was bound down by adhesions and was gangrenous and contained pus. Appendix was removed; large quantity of offensive pus found in pelvis.

Glass drainage put in pelvis, and three pieces of iodoform gauze packed in, ends being brought out lower part incision. Balance of incision closed with silkworm-gut sutures. Urine albuminous with hyaline and granular casts.

Patient died on third day after operation of septic peritonitis.

Case 7.—M. M., 13 years. Admitted Nov. 15, 1900. Has never had an attack of acute abdominal pain. Has had several bilious attacks in which he had headache and vomiting.

Two days before admission he began to feel sick, nausea and vomiting. The night before admission he was suddenly taken with acute abdominal pain—very severe cramp colic—and vomiting. His bowels moved on day of admission. He had no chill.

When admitted had temperature 102. Pulse 124 and rather weak. He was cyanosed, hands were cold, complained of much pain and tenderness in abdomen. Passed no flatus. Abdomen was very rigid, tender, slightly distended, and tympanitic.

Under ether, the abdomen was opened through the right rectus. Upon opening the peritoneum the pus gushed forth. The abdomen everywhere was filled with foul-smelling, yellowish, thin pus. The intestines were very much inflamed, and in some places covered with lymph and plastic exudate. The appendix, which was behind the cecum, was slightly adherent, gangrenous, perforated in the middle. It was ligated and removed. The abdominal cavity was flushed very thoroughly with saline solution. A glass drainage put in pelvis, and five pieces of iodoform gauze.

During the operation he had a poor pulse, so rapid that it could not be counted. After the operation it was very weak. He vomited, became delirious and very restless. Morphin was given, but it did not act and he suddenly died 21 hours after operation of purulent peritonitis.

Case 8.—B. W. S., age 22 years. Admitted May 31, 1900.

First attack two weeks ago after riding wheel very fast. Was taken suddenly sick with severe pain in abdomen, which became localized on right side. He was treated for a sprain; has been getting progressively worse. Pain not so severe.

On admission: Very tender right side; a fluctuating mass can be felt in the right iliac fossa.

Operation: Incision about 6 inches long made through right rectus muscle; after walling off general cavity with sterile gauze, abscess opened, contained 500 or 600 c.c. offensive pus. Appendix behind cecum and perforated. Second incision was then made in flank to secure free drainage. Abscess cavity packed with iodoform gauze, and incision closed with silkworm-gut.

Patient died 12 hours after operation of shock and peritonitis.

Case 9.—P. B. J., age 26 years. Acute appendicitis. Admission Feb. 5, 1900.

Patient was too ill to get a history. Only a few questions were asked. It was his first attack. Had been taken ill suddenly one week before coming to the hospital. Thought he had an ordinary bellyache and did not send for the doctor until two days later. There was at first great abdominal pain and tenderness all over the abdomen, accompanied by vomiting. The pain gradually localized in the right iliac fossa, and became more severe.

On admission: Patient was having considerable pain, and was exquisitely tender. The rectus was rigid, and there was a mass in the right iliac fossa.

February 6, operation: Patient etherized and a long incision made through the rectus. The cecum and a part of the ilium gangrenous. There were numerous adhesions. In the effort to free the appendix a large abscess below the cecum was ruptured, and a quantity of foul pus liberated.

Blood count: Hemoglobin, 78 per cent.; erythrocytes, 5,020,000; leucocytes, 41,600.

Died 36 hours after operation. Temperature 104 degrees.

Case 10.—Miss M. S., age 27 years. Admitted June 10, 1900.

On admission the patient had pain in the right iliac fossa. There was rigidity, tenderness and dulness in the right iliac fossa. Vaginal examination revealed a tender mass to the fossa of the cervix.

June 10, operation: Incision through the right rectus. Cecal region walled off with gauze. Appendix found turned on itself and behind the cecum. In the attempt to release it an abscess was evacuated. Appendix ligated and cut off. Two pieces of iodoform gauze and a rubber tube were put in as drainage.

Urine albuminous, granular casts.

Patient died on the third day with symptoms of general purulent peritonitis. If organ had not been searched for the abscess would not have been discovered.

Case 11.—W. B., age 52 years. Acute appendicitis. Admitted July 7, 1900.

Family history negative. Always in good health until 50 years of age. Complained then of malaise. Appetite good; bowels constipated; throat felt dry; drank large quantities of water. Passed large quantities of urine. One year ago had right leg bruised. Broke down and had open sore for two or three months. Six months ago noticed left big toe black and stiff. Small sore under toe which was discharging. This went on until had an ulcer along tendon leading to big toe; three months later toe came off; no pain. Now complains of dryness of mouth and throat. Drinking does not satisfy. Is beginning to lose appetite; some nausea and vomiting; lost weight; 12 days ago had an attack of cramp-like pains in abdomen; came on suddenly; nausea and vomiting. Three days later had fly blisters put on right side. This raised blister which instead of healing left two running ulcers.

On admission: An exquisitely tender and very hard mass can be felt in the right flank and iliac fossa. No fluctuation at this time. Later the mass broke down and showed fluctuation. Not so tender.

Operation: Incision about 2 inches long made transversely above crest of ilium under local anesthesia. Large quantity, 500 c.c. E, dark vile-smelling pus evacuated. Abscess cavity washed out and three pieces rubber tubing inserted for drainage. Wound then dressed antiseptically.

While pus was being evacuated a piece of rotten tissue came out, was about 4 inches long and ¼-inch wide. Could not tell what kind of tissue. Supposed to be appendix. Died on third day after operation in diabetic coma.

Case 12.—H. K., age 17 years. Acute appendicitis. Admitted June 8, 1900.

Always in very good health until two months ago, when had an attack of appendicitis. Was then sick for several days. Attack came on suddenly with cramp-like pains in abdomen, very severe. These pains lasted for several hours, then had pain in lower part of abdomen, particularly in right side. Was then up working on delivery wagon, noticing at times slight pains in right side when jumping off wagon. Two weeks later had another attack lasting three or five days. Few days later had third attack, was sick for two days, but did not have to go to bed. Present trouble began two days before admission; had cramps in abdomen for short time, since then had continuous pain in lower part of abdomen and right side. Has vomited twice. Examination shows tenderness on pressure in left and right inguinal regions. Rectus muscles, both sides, more rigid than normal, especially right.

Operation: Incision about 3 inches long made through right rectus muscle; appendix found in pelvis bound down by adhesions. After protecting general peritoneal cavity by packing with gauze, adhesions broken up, finding several c.c. of purulent, bad-smelling pus.

Death due to general septic infection.

Did not have a general peritonitis; in this case the abscess was not discovered until the appendix was searched for.

Case 13.—C. C., age 22 years. Acute appendicitis. Admitted Dec. 24, 1900.

Patient has always been in good health with the exception of slight colds and an attack of influenza. His habits good. Does not use tobacco or alcohol. Denies venereal diseases. Has never had an attack of appendicitis before. Bowels regular. Appetite and digestion good.

Five days before admission he complained of feeling unwell. He had pain under the lower border of ribs on the right side. He had no appetite. Bowels moved regularly.

The pain became worse and more general, but more marked on right side, from the level of the umbilicus to the lower border of ribs. The pain was constant and cramp-like, and two days later there was marked tenderness all over right side, high up, near gall bladder, but pressure over the appendix caused the pain to become worse. Appendicitis with the appendix pointing up toward the liver was diagnosed. There was no marked distension or dulness.

Under ether an incision was made at McBurney's point. The abdominal walls were not thoroughly relaxed. The appendix was very long, and ran under the cecum up to the liver, and was gangrenous in three places. It could not be delivered in the usual manner, so the proximal end was ligated and then pulled out without ligating the appendicular artery, which was so deep that it could not be reached. There was pus present behind cecum. Drainage by rubber tube in loin and six pieces of iodoform gauze.

After operation his pulse became very rapid and there was a marked hemorrhage through the loin incision, which was controlled by packing with gauze.

His abdomen became distended on second day; pulse was very weak. He received streptococcic serum, but it had no effect. He was transfused four times the last 36 hours before death, receiving 8500 c.c. salines. He became restless, delirious, and on receiving hyoscin and morphin, he slept until the end without being conscious.

Incision was not opened for postmortem.

December 25: Hemoglobin, 95 per cent.; erythrocytes, 4,110,000; leucocytes, 14,200.

December 26: Hemoglobin, 90 per cent.; erythrocytes, 4,150,000; leucocytes, 20,400.

Probable post-operative gangrene of cecum. The hemorrhage after operation was an important factor in this man's death, as it lowered his powers of resistance.

Case 14.—J. D. Acute appendicitis. Admitted May 7, 1900.

Had been sick for three days; was taken suddenly sick with acute pains in abdomen, which became localized in right side; bowels constipated. On admission found exquisite tenderness, right side. Rigidity of right rectus muscle. Mass can be felt in right flank.

May 8, operation: Incision through right rectus muscle. Appendix behind cecum bound down firmly by adhesions. Abscess behind cecum extending upward and backward. Appendix perforated at distal end. Abscess evacuated and appendix removed and hole in cecum closed. Incision made in flank, rubber drainage tube inserted. Abscess cavity packed with six pieces of iodoform gauze.

May 9, 7 a. m; few râles noticed over right side of chest; 10:20 a. m., crepitant râles; increased fremitus and resonance, right base; slight cough.

Died on second day after operation of pneumonia.

Urine contained albumin and casts.

Case 15.—J. S., age 52 years. Acute appendicitis. Admitted March 24, 1900.

Patient was suddenly taken ill two and one-half days before admission, with pain, nausea and rigidity. Pain became localized to right iliac fossa. Operation advised, and took place 20 minutes after arrival in hospital, so that little history was obtained.

Much pain, distension, and shock on admission. No flatus or feces passed for 12 hours. Probably due to a paresis of bowel.

March 24, operation: Incision 5 inches long in right rectus. Peritoneum opened; bowels red, injected, and much distended. Appendix behind cecum, bound down by adhesions and gangrenous. Patient died on operating table.

Case 16.—C. H., age 21 years. Acute appendicitis. Admitted May 28, 1900.

Sick four days. Attack came on suddenly with severe pain in abdomen, nausea, vomiting and constipation. No passage of gas. Abdomen distended, muscles rigid and exquisitely tender.

Operation: Found general purulent peritonitis. Appendix bound down by dense adhesions, and surrounded by inflammatory lymph. Appendix, which pointed toward pelvis, was gangrenous, as was cecum near attachment of appendix. Appendix ligated and excised. Glass drainage with four pieces of iodoform gauze packed around.

Patient did not come out of ether, and died four hours after operation.

Case 17.—E. A. G., age 28 years. Acute appendicitis. Admitted May 19, 1900.

Has had trouble for several years.

Operation: Incision made parallel to Poupart's ligament, opening up abscess which extended down into the pelvis. Second incision then made through right rectus muscle, intestines bound together with firm adhesions, and between the coils numerous small cysts filled with dark, cloudy fluid. Appendix, which was gangrenous, was found in pelvis, was ligated and removed. Large cyst of right broad ligament, both ovaries cystic.

Glass drainage tube and two pieces of iodoform gauze put in place, and incision partly closed with silkworm-gut sutures. First incision packed with iodoform gauze.

During operation patient's lungs and trachea became full of mucus. Pulse weak and rapid. Face blue. Inability to breathe. Tracheotomy then done and patient revived after artificial respiration kept up for several minutes.

10 p. m., patient transfused 3000 c.c. saline solution. Died at 6 a. m., 12 hours after operation, from shock.

Case 18.—J. B., age 19. Acute appendicitis. Admitted Nov. 20, 1900.

Has never been sick in bed. Had several slight colds. Denies gonorrhea and syphilis. Had an attack of abdominal pain which lasted four days in August.

Had an attack of acute abdominal pain at 10:30 last night. Came on gradually with acute pain all over the abdomen, localized near umbilicus. No localized pain at McBurney's point. Bowels moved soon after attack began. Was nauseated and vomited. Could not sleep on account of pain, which was dull in character with occasional paroxysms. Had eaten nothing unusual before the attack.

When admitted had pulse of 116. Temperature 101 4/5. Had received a hypodermic of morphia before he was admitted, from effects of which he was drowsy. Had no pain and was not tender on gentle touch over the appendix or on the left side. The abdomen was markedly rigid on both sides. No dulness noted. Did not vomit. Lungs clear; heart normal; liver dulness, not enlarged; spleen normal.

Operation: Under ether, an incision was made through the right rectus muscle. On opening the peritoneum, pus escaped. There was pus all over the abdomen. The bowels were injected. Large pieces of gauze were put into abdomen to wall of the bowels, and the appendix, which occupied the pelvis, was then delivered, ligated, cut off, and the stump washed with bichlorid and carbolic solution. A glass drainage tube was introduced into pelvis, and there was a great discharge of pus. The most of the purulent matter, which was creamy in color, and of not very foul odor, was in the pelvis. A large piece of iodoform gauze was put down into the pelvis, one along the cecum, and one over the intestines. Three pieces of gauze and a glass drainage tube left in. The wound was partially closed with silkworm-gut sutures through and through.

Second day after operation, began to have distension of abdomen, passed no flatus. Pulse became weaker. The distension soon became marked. He began to vomit and was restless. The gauze was removed on the fourth day, when he showed all the symptoms of a general peritonitis. He was transfused with 2000 c.c. salines. He was conscious to the end. The pulse was better after the transfusion for six hours only. He died while vomiting; the vomit seemed to get into his larynx and strangle him. Urine scanty and albuminous, with granular casts. General peritonitis.

CASE 19.—M. K., age 25 years. Acute appendicitis. Admitted Aug. 19, 1900.

Had had several well-defined attacks of appendicitis during the past four years, none of which, however, were very severe.

Present illness began suddenly 10 days before admission, with severe cramp-like pains in the abdomen accompanied by diarrhea and vomiting. Later the pain localized itself to the right iliac fossa, where he was very tender and a mass could be distinctly palpated.

Operation: Performed immediately after admission. Incision 5 inches long through right rectus muscle. Bowels packed away with sterile gauze. Abscess found behind the cecum, with the appendix, which was inflamed, bound down in the pelvis by adhesions. Adhesions broken up and appendix ligated and removed.

Patient reacted from the ether, but during the second twenty-four hours after operation vomited a few times. Passed gas freely and bowels moved on the second day and stomach became retentive. Patient was excessively nervous and at times became delirious.

Tube became perfectly dry on the 4th day, and was removed along with the gauze and replaced by two rubber tubes. Patient's nervousness and restlessness increased every hour, in spite of all that could be done to control it, and he died finally of exhaustion on the 7th day after operation, due to septic infection.

Urine scanty and albuminous, containing hyaline and granular casts.

CASE 20.—J. K., age 29 years. Acute appendicitis. Admitted Dec. 7, 1900.

Father, mother, two brothers and two sisters living and well. No family history of phthisis. Had the milder diseases of childhood. Enteric fever in summer of 1899. Has not been well since. Always complained of pain in chest and abdomen.

Nov. 5, 1900, was taken suddenly sick with abdominal pain, which was very severe for a few hours, and came on again from time to time. December 1, he was again taken with severe pain, vomiting, tenderness in right iliac fossa which gradually grew worse. Had history of phthisis. When admitted he had a mass in right iliac fossa, prominence of wh could be seen. He was very tender, there was dulness present and marked rigidity. He was operated upon as soon as admitted.

Under ether, incision was made through right semilunar line; there was a large mass on right side walled off by small bowels and omentum. The abscess cavity was between the parietal peritoneum and the cecum. This was opened and thoroughly cleansed by bichlorid solution. Part of the omentum was indurated; this was tied and cut off. The appendix was on the cecal side of the abscess. It was gangrenous, very large and fragile. It was tied off and removed.

Five pieces of iodoform gauze and a glass drainage tube was put into abscess cavity and part of wound closed with silkworm-gut sutures.

After the operation his pulse was better than before. He was restless, vomited and hiccoughed a great deal. Tube was cleaned, and contained pus and blood. He did not cough. Stomach was not retentive. Twelve hours before death he became very restless, pulse became very weak. He was conscious to the end. Vomited fecal matter, bowels became very loose, and died with symptoms of peritonitis.

Blood count: Hemoglobin, 68 per cent.; erythrocytes, 4,470,000; leucocytes, 19,000. Urine albuminous and casts. General purulent peritonitis.

CASE 21.—M. S. M., aged 30 years. Acute appendicitis. admitted Sept. 25, 1900.

Has had six attacks of appendicitis of varied intensity and duration, from a few hours up to 10 days. Usually vomited with the attacks.

Present attack began 24 hours before admission; had had diarrhea for a day or two before. Was suddenly seized with general abdominal pain and vomiting, after a few hours pain became localized to right iliac fossa, where it became very severe, and was accompanied by exquisite tenderness. Pain was so severe that he had taken 2½ grains of morphia in the twenty-four hours before admission, without entirely controlling it.

On admission: Temperature 102, pulse 96 and soft. Abdomen slightly distended; right rectus very rigid; exquisitely tender in right iliac fossa, where there is a sense of fulness on palpation, although no distinct mass can be made out.

Incision 6 inches long through right rectus muscle. Appendix found to be perforated and gangrenous, and to be tied up with the cecum. and small bowel in mass of adhesions. A small quantity of pus around the appendix. Pus evacuated and appendix freed, but on tightening it, tissues so friable that it cut through. Hole in cecum closed as well as possible, but owing to its devitalized condition stitches cut out very often. Meso-cecum brought over the place and fastened there; omentum too gangrenous to serve. Lower part of omentum ligated and cut off. Three pieces of iodoform gauze packed around the infected area separating it from the general abdominal cavity. Upper and lower parts of wound closed.

Patient came out of ether all right, but after a few hours general peritonitis set in, and patient died about 60 hours after operation.

CASE 22.—Mrs. R. O'B. Acute appendicitis. Admitted Jan. 19, 1900. Has always had good health. No previous attack of appendicitis.

The patient was taken ill with fever, slight abdominal pain, some diarrhea, headache, pains in back and legs, and marked malaise. This was about seven weeks before she was brought to the hospital. For some time she was treated on the supposition that she had influenza of the gastro-intestinal type, or a mild enteric fever, although there were no spots or nose bleeding. Then the diarrhea was followed by constipation, the abdominal pain became much more severe, and was cramp-like, the right iliac fossa began to be markedly tender on the slightest palpation, and on careful examination a slight localized mass could be made out in the appendiceal region. There was no vomiting. The patient and family were advised that an operation was necessary, but refused to follow the advice. Patient gradually lost flesh and strength, and attained a septic appearance. At times she would perspire freely, and at other times have chilly sensations. The pain gradually disappeared to a large extent. The mass was easily palpable. The fever persisted and was decidedly septic in character. Finally an operation was consented to.

Operation: January 21, an incision about 4 inches in length was made through the right rectus muscle. An abscess about the size of a goose egg lay back of the cecum, and in this lay the gangrenous appendix, running up to the posterior aspect of the cecum so that the tip almost reached the lower border of the liver. The pus was evacuated, and the appendix, with the neighboring necrosed structures and indurated masses of tissue, was removed. The weakened and in places slightly ruptured portions of the posterior aspect of the cecum were sutured with fine black silk. A counter incision was made in the flank to permit through-and-through drainage.

Urine albuminous. Hyaline and granular casts.

Died on the 12th day after operation. Bowels very loose from operation to time of death. Pulse rapid and weak.

Symptoms pointed to death from septic absorption from gangrenous bowel.

CASE 23.—J. E. V., age 36. Acute appendicitis. Admitted Nov. 23, 1900.

Has never been sick in bed except with appendicitis. Two years ago had an attack of appendicitis. Was sick six weeks. Bowels inclined to be constipated. Had an irritable stomach.

Present attack began about 10 days before admission; had pain in his abdomen, which became very severe a few days before admission. Vomited very often. Pain and tenderness were much worse on right side. When admitted he had temperature 101, pulse 112. Had a large mass in right iliac fossa.

Under ether an incision was made on the right side, going through the rectus muscle. The appendix, which pointed towards the pelvis, was bound down by many adhesions. The large and small bowel were adherent. The adhesions were separated in freeing the appendix, which was markedly inflamed and surrounded by pus. The appendix was ligated and removed.

Developed a fecal fistula a few days after operation. Patient was never strong after operation. Stomach was irritable. An abscess developed in right buttock. Several days before his death there was pus in his stools, and after it made its appearance he began to sink. It was caused by the rupture of a deep abscess in his buttock, rupturing into the rectum. This wound was opened after death. The intestines were in good shape. The kidneys were enlarged, and the seat of parenchymatous inflammation. Underneath the peritoneum and traveling along the psoas muscle was an abscess which pointed in the buttock, and ruptured into the rectum. This so weakened him that he finally became delirious and died.

Urine albuminous with hyaline and granular casts.

On admission, blood count: Hemoglobin, 75 per cent.; erythrocytes, 4,970,000; leucocytes, 14,800.

Case 24.—C. L., aged 17 years. Acute appendicitis. Admitted Jan. 29, 1900.

One week before admission the patient was suddenly seized with a pain in the right iliac fossa. While there was some general abdominal pain, it was most acute in the lower right quadrant. Bowels had been sluggish for some time before this. Vomiting started the second day. These symptoms, with great tenderness, persisted until the third day, when all the symptoms diminished in severity. On the day before admission to the hospital an exacerbation of the symptoms occurred, the patient suffering more than in the beginning of the attack. On admission it was found that there was exquisite tenderness and a mass in the right iliac fossa. The right rectus was markedly rigid.

Operation: A long incision was made through the right rectus muscle. Immediately upon opening the peritoneum a large quantity of malodorous pus escaped. The intestines in the lower right quadrant were matted together by adhesions, and there was an abundance of organized lymph gluing everything together. After considerable work separating the bowel, the head of the colon was freed sufficiently to locate the appendix. It was in such a position to the inner side of the cecum as to point toward the spleen. There was a small perforation near the distal end, and the entire organ was encased in organized lymph. As the cecum could not be brought out of the wound, the appendix was ligated and cut off the cecum. Glass drainage.

February 22. Intestinal obstruction: The patient has been having severe pains off and on for a week or two, and they have been growing worse, coming oftener, and lasting longer. Yesterday he began to vomit. To-day vomiting, no flatus and the outline of the bowels showing on the surface of the abdomen. Great pain. In a fit of coughing broke the wound partly open, and the intestines protrude.

Old incision opened; numerous adhesions found, and at one point the ileum was caught in such a way as to be an obstruction to the lumen of the bowel. Below this point it was collapsed, above inflated. The bowel was freed and all adhesions broken up, and the wound closed as usual.

Patient died within 12 hours after the second operation. Intestinal obstruction from adhesions.

Case 25.—A. B., aged 50 years. Acute appendicitis with abscess. Admitted Aug. 23, 1900.

Patient was admitted on the eighth day of an attack of acute appendicitis. Could speak Italian only, and no history was obtainable. On admission temperature was 100 degrees, pulse 96. Has a large tender mass occupying the right iliac fossa.

An incision 7 inches long was made through the right rectus muscle. Immediately on opening the peritoneum a large collection of pus was encountered; this escaped both externally and into the general peritoneal cavity.

The abscess wall was found to consist of thickened mesentery and coils of small bowel, glued together by inflammatory exudate. Appendix, which pointed toward the cecum, was ligated and removed.

The patient came out of ether nicely, and was comfortable all night, but on the next day general peritonitis began, and the patient died 48 hours later.

Case 26.—J. S., age 20. Appendicitis; chronic ovarian cyst. Admitted Aug. 7, 1900.

One year ago had an attack of appendicitis, was sick six weeks. Since then complained of a feeling of fulness and some pain in the right iliac fossa. No nausea or vomiting. Menses normal.

Examination shows tenderness on pressure in the region of appendix.

Operation: Incision made through right rectus muscle. General peritoneal cavity walled off with gauze; found ovarian cyst about size of an orange. Appendix in pelvis, and bound to cyst by numerous adhesions; many small cysts between knuckles of bowels, filled with yellowish, muddy fluid. Adhesions broken up and right tube and ovary removed. Cyst was filled with dark-yellowish, cloudy serum. Appendix, which showed chronic inflammation changes, was ligated and removed. Great omentum was adherent to cyst. These adhesions broken up, omentum ligated and about 1½ inches excised. Glass drainage tube put in place and wound closed.

Patient was apparently doing well after operation, bowels moving freely on the second day. On the third day glass drainage was removed, and wound closed completely, by tying the previously introduced stitches.

Twenty-four hours later symptoms of general septic peritonitis began, with pulse of 132. Vomiting was practically continuous, and in a few hours became the typical black vomit of septic peritonitis. Abdomen became tympanitic and was extremely tender. Twenty-four hours after onset of peritonitis, the lower part of the incision was opened, and the abdomen flushed out and drainage again introduced. This, however, failed to arrest the progress of the disease, and the patient died on the sixth day after operation.

Infected at the time of removal of the drainage tube.

Case 27.—E. D., aged 38 years. Acute appendicitis. Admitted April 2, 1900. Had congestion of brain and spine three years ago. Present trouble began February 10, complained of general abdominal pain, cramp-like in character; later pain localized, right side. Bowels regular. Vomited for 3 or 4 hours.

On admission find mass in right side about 4 inches long by 2 wide, very hard, and painful to touch. Can not straighten out right leg. History of having passed pus from bowels four times.

First incision 3½ inches long, made just inside anterior superior spine of ileum, near mass, at angle of about 45 degrees to Poupart's ligament and running up and outward above anterior superior spine. On reaching external oblique muscle, found it hard and indurated from inflammatory infiltration. On cutting deeper, knife entered mass soft broken down anterior. This was washed out with carbolic and bichlorid. Lightly packed with two pieces of iodoform gauze.

Second incision made to right median line through right rectus muscle into peritoneal cavity. On elevating abdominal wall, found ileum and cecum adherent to parietal peritoneum; cecum separated from peritoneum with difficulty. This done, the appendix was found behind and to the outer side of cecum, enmassed in considerable amount of organized lymph.

Blood count; Hemoglobin, 70 per cent.; erythrocytes, 3,840,000; leucocytes, 21,580. Urine normal. Died on third day after operation of general purulent peritonitis.

This case is probably one which was infected at the time of operation, although every precaution to protect the peritoneum was taken. Abscess of the abdominal wall.

Early Sign of Measles.—Two French writers have recently called attention to the sore throat, studded with white dots, which they have observed in a large number of cases of measles. This sore throat precedes the other symptoms of measles by several days, and the diphtheria bacillus was found in the throat in several instances, leading to an erroneous diagnosis.

SYMPTOMATOLOGY OF CEREBRAL HEMORRHAGE.[*]

F. SAVARY PEARCE, M.D.
Professor of Nervous and Mental Diseases in the Medico-Chirurgical College of Philadelphia; Neurologist to the Philadelphia Hospital.
PHILADELPHIA.

The symptoms of cerebral hemorrhage, in unison with many other of the acute affections of the central nervous system, are so frequently aberrant and simulated by different diseases producing a sudden insult to that vital organ of the body, the brain, that rehearsing the subject as a whole seems timely before this representative body. We shall dwell upon the cardinal symptoms in due measure, we trust, and yet hope to point out the more unusual signs resulting from rupture of the cerebral vessels. Coming under the head of cerebral hemorrhage, not only an extravasation of blood in or about the brain, but thrombosis or embolism producing acute softening, which latter is indeed difficult to distinguish from a slow exudation of blood within the encephalon. This latter condition was shown recently in consultation with Dr. Küsel in a man, aged 63, visited on March 7, 1901. There was no history of alcoholism or specific disease. He had had, five years ago, an "attack" in which vertigo was a prominent symptom, there being no paralysis resultant, but he was left with difficulty of speech (motor aphasia) and acute asthenia following the injury to the brain, which confined him to bed for three weeks. The man had never been well since; he complained of feebleness but no paralysis, the speech defect remaining up to the day of his present illness, which occurred Feb. 1, 1901. His speech first becoming worse as to the aphasia, he was taken to his bed with what was pronounced a complicating attack of influenza. About a week after he had been confined to the bed, it was noticed there was some weakness of the right upper and lower extremities, and of the body. There was never conjugate deviation of the eyes. When I saw him on March 7 he was moribund; there was no pupillary response, nor could reflexes be detected anywhere. The temperature in the right axilla was 105.8 F.; in the left axilla, 105. The bladder was distended with urine which, when drawn, proved negative; this in all probability eliminated nephritis as an etiological factor.

The particular symptom occurring for three or four days before death perhaps has some weight in the diagnosis of these cases from hemorrhage *per se*, i. e., the symptom of decided mental excitement, still somewhat under the control of the individual. This was shown by the fact that this man, during the spells of hallooing at the top of his voice, could be quieted for the time being by his wife's forcibly correcting him, the patient relapsing again into excitement; he could not explain why he had cried out so. As said before, it seems to me that this symptom deserves some stress laid upon it as a sign of acute softening of the brain rather than massive hemorrhage, where, as in this case, it is difficult to determine the extent of the motor paralysis.

At necropsy, we found an area of softening in the left parietal lobe extending down to the lateral ventricle, the size of a silver dollar at its base on the cortex, due to arteriosclerosis of the cerebral arteries, especially of the posterior cerebral artery.

Symptoms of a typical case of cerebral hemorrhage are divided into those of the acute stage and those of the later or chronic stage. While the patient may have been feeling some premonitory signs, such as dizziness, headache and dulness of mentality for some days or weeks before the onset of the attack, still it is the rule that he is feeling particularly well immediately preceding the apoplexy, which in the majority of instances occurs during the sleeping hours of the night. This fact has always interested me from a psychological point of view, and is probably explained by the fact that inhibition generally is lessened during the early hours of the morning and very likely there is much less resistance within the encephalon, thus allowing overdistension of the cerebral vessels which produces the "breaking strain" in sclerosed cerebral arteries. This does seem somewhat paradoxical when considered in relation to physics, since increase of vascular area and therefore capacity to bring lessened arterial tension at any given point; but as inferred above, the greatly reduced "force de résistance" at the vulnerable point occurring at the site of a patch of sclerosis and fatty degeneration, will permit overdistension of the media and thus rupture. The patient, therefore, in 50 per cent. of instances on awakening, discovers that he is paretic or totally paralyzed in one side of the body. There may be little or no sensory phenomena so-called; the effort to move alone attracts his attention; or it may be that a motor aphasia is the only symptom the patient complains of, which in itself produces a mental excitement from apprehension as well as, no doubt, from disturbing the proper co-relation of neuronic force—the so-called nervous energy. This leads me to the suggestion to apply this same theory of disturbed nerve currents (somewhat identical with the ultimate result of disturbance of nerve energy due to the coaptation or retraction of the protoplasm of the neuron—the so-called neuronic theory) in explanation of the peculiar emotional state of the person suffering from cerebral hemorrhage. This manifestation of the psychology of apoplexy very likely may be produced by the abrupt severance of the proper association of other concept centers with the center of ideation.

If the hemorrhage has been massive, the patient will, of course, be found comatose. The conjugate deviation of the eyes will occur towards the affected side, the pupils will be dilated generally one more than the other and will be only slightly responsive to light stimuli. The reflexes will be found abolished on the affected side at this stage. At the end of a few hours, the knee-jerk and other reflexes which have been abolished now return and become increased from day to day due to irritation of the motor tract from the cerebral lesion whether it be a hemorrhage, embolus or thrombus. The patient will breathe heavily; perhaps the Cheyne-Stokes style of respiration will prevail. The temperature will be found increased both on the surface, where the affected side of the body shows an increase of 2/5 or 3/5 above the opposite side, the degree of caloric developed being 102 to 103 in the axilla and slightly above this when taken under the tongue or in the rectum. The patient generally lies supine, the paralyzed extremities may be hyperesthetic and within an hour or so when consciousness partially returns, if the case progresses favorably, the patient will frequently brush away the clothing or any irritating body, as a house fly, which may light on the paretic member. If the patient is to recover, the temperature drops at the end of four or six hours; the pulse which had been slow and full will become softer and will increase in frequency to slightly above the normal. Flushing and cyanosis of the face will then disappear and the mentality be restored gradually, although the mental anxiety and lacrymoses may be shown at once in the physiognomy of the patient, aside from any paralysis in the face or vocal apparatus which may maintain. This sudden change of expression of the individual is an interesting and sad indicator of the havoc played by extensive organic rupture in the brain mass. There usually is a secondary rise of temperature even in a favorable case, due no doubt to irritation of the heat regulating mechanism; finally, after six or seven days, the temperature will remain irregular and hovering about the normal line. Within ten days or two weeks in the average case, the patient may be able to move about with the assistance of crutches if his previous condition of health has been fair; if he has been in a low stage of health, the ability to use the musculature will be proportionately lessened, all depending therefore on the idiosyncrasy and reserve nerve force. As a rule, it is safe to say that the patient's nervous system is insulted enough by any sort of hemorrhage to warrant absolute quiet for a fortnight, which should be carried out religiously by the physician if relapse is to be prevented.

---

[*] Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

The diagnosis of pachymeningitis interna hæmorrhagic might at first seem unnecessary to mention in a paper on symptomatology of cerebral hemorrhage, but the condition is most difficult to diagnose. Two cases recently coming under my observation will uphold this view.

In my own case, that of J. McM., white, age 38, admitted to the Philadelphia Hospital on March 4, 1901, gave a history of previous venereal infection and that he had always been a heavy drinker. He had lately been intoxicated for three weeks, had mental stupor when first examined with hallucinations of hearing and sight. For the past three years he has been more or less a sufferer from shooting pains in the legs which he says were slightly rigid; this rigidity did not grow worse, although there was no lessening of the symptom. About two months before admission, the patient complained of incontinence of urine; and about a week previous to admission, of incontinence of the rectal muscle. On examination, the pupils were equal and slightly irregular in outline, the right pupil being smaller, both reacting sluggishly to light. The tongue was protruded straight; the speech was slow but not tremulous; the pulse was slow, intermittent, irregular. There was marked arteriosclerosis. The patient lay heavily in the bed in log-like inactivity, moving the arms and legs but slightly. The right leg was markedly spastic, the knee-jerk being very much exaggerated but the spasticity so great as to prevent the development of ankle clonus. There was no local atrophy; there was hyperesthesia of the plantar surface of the right foot; there was no Babinski reflex; there was but slight spasticity of the left leg and foot. Knee-jerk was greatly exaggerated and feeble ankle clonus was present. Sensation of pain and touch seemed absent over left foot and leg to the level of the knee; there was feeble plantar reflex on the left; sensation was retarded over the remaining portion of the left lower limb. There was much spasticity of the arms, the patient being lifted from the bed while lying supine, when there was forcible extension of the forearms of the right side, evidently caused by the contraction of the scapular and trapezius muscles. The spasticity was of lead-pipe quality, more marked on the right side, but also present as stated on the left. Sensation to pain was present, not localized as to point of pressure, but referred downward in the course of the periphery of the nerve.

Examined March 8, it was noted that the left pupil was twice as large as the right; the man was in a semi-conscious condition; answered questions only in monosyllables; there was marked tremor of the lips; the right elbow could not be extended to a right angle, the right arm being held pronated. The patient had a fair grasp in the right hand; but there was no grasp in the left hand, though the spasticity in the left arm seems almost as great as that in the right; the right leg was very spastic and a large tremor grew as it was raised from the bed. There was no clonus on the right side nor on the left to-day; there was no evidence of ecchymosis anywhere. There was flexion of ankle on irritating the sole of right foot, although the toes themselves did not extend as is usual in the Babinski reflex; in the left foot, the toes did extend on irritating the sole, although there was not as much extension as of ankle flexion as compared to the right side. The skin was reddened in the sacral region. Hearing was much obtunded, although he could appreciate the watch tick on contact. There was some slight retraction of the neck. Patient lies supine. There is no form of aphasia present to account for the difficulty of expressing himself; this being entirely mental. There is no astereognosis in the right hand, but the left hand seems to be anesthetic in the palm and up to the forearm to the elbow, making absence of ability to appreciate objects in shape and size.

March 9, the patient is more stuporous, although he will answer questions in monosyllables.

March 10, patient seems somewhat brighter, complains of general pain in the head. Pupils are almost equal in size. Right arm can be moved quite freely; left arm is spastic and can not be moved by the patient. He can move right leg freely, and left leg not at all. Both legs are slightly spastic, but much less so than two days ago.

March 11, patient is perspiring freely. Seems rational, although he talks in a very low voice. Complains of pain in chest. A few sonorous râles. Resonance clear.

March 13, patient is incoherent; will obey commands, however; opens and shuts his eyes.

March 16, pulse soft and rapid. Respiration rapid and shallow, not stertorous. Temperature gradually rose to 103 degrees. Death supervened.

Autopsy.—Upon opening skull cap, considerable blood escaped and a large hemorrhage was found. This proved to be subdural, and on the right side. It extended from the occipital to the frontal lobe and downward to the Sylvian fissure, extending into the latter so as to separate the temporal and opercular convolutions from the island of Reil. A glass held below the skull as the brain was removed, collected 50 c.c. of blood and cerebrospinal fluid. When the dura mater, containing a large clot, was removed, the surface of the brain was considerably flattened; therefore must have been under considerable pressure. Vessels of pia were deeply congested. On opening left lateral ventricle, it was distended with cerebrospinal fluid, lateral ventricle of right side compressed so as to be almost occluded. Choroid plexus of left side terminated in a soft tumor the size of a soap bean.

Case II.—Through the kindness of Dr. James Tyson, I am permitted to report a case of similar nature though the lesion is on the left side of the brain. The man was admitted to the medical wards of the Philadelphia Hospital, and died of chronic nephritis.

Male, white, aged 71, semiconscious on admission, due to the uremia. He was able to walk about at the end of a week, with spastic hemiplegia, right side. How long, as in my own case (3 years), he had been afflicted with the dural disease, does not appear from his vague statements; although he was likely afflicted many months.

Autopsy.—Dura mater quite adherent to skull over left hemisphere; and pachymeningitis interna hæmorrhagica was found. Hemisphere below this was somewhat compressed; and the lateral ventricle below it was collapsed. Brain itself was normal. Hemorrhagic area extends over the whole superior and external portion of the left hemisphere, descending to the level of the fissure of Sylvius.

Paralysis is never so complete in the hemiplegia from pachymeningitis interna hemorrhagica, for if complete, death would supervene. Therefore, in a given case of hemiplegia, a positive sign that it is not due to dural hemorrhage, would be in the occurrence of complete pachymeningitis. Fifty per cent. of cases are unilateral in pachymeningitis hæmorrhagica.

Ingravescent hemorrhage and pachymeningitis interna hæmorrhagica have some points in common which are confusing in diagnosis. In both there is apt to be no loss of consciousness; although in the former there is less likelihood of rise of temperature, while in the latter there is elevation of the temperature curve to 102 or 103 or more degrees F., but of irregular type and associated with rather severe pain in the head. Then the spasticity which would occur from cortical irritation from pachymeningitis, would be the positive point as against hemorrhage in the external capsule.

Another differential point in diagnosis between ingravescent hemorrhage and subcortical tumor in the motor area, is to be made in some cases. The history of the case would be important as bearing upon this subject, as well as the examination of the eye grounds where optic neuritis would be present and of high grade in the case of tumor; it almost never being present in the slow hemorrhage, since the neuritis would not have time to develop at the moment of examination.

Hemorrhage into the crus cerebri would be told by the irregularity of symptoms in the first place, and secondly from the alternate hemiplegia following and generally associated with some sensory loss on the hemiplegia side and accompanied by paralysis of the oculomotor nerve on the same side.

Hemorrhage into the pons is very difficult of determination but would be told by critical examination for a crossed paralysis affecting the face on the same side, as hemiplegia in the case of hemorrhage into the upper portion of the oblongata; or secondly, of the face on the same side, if the hemorrhage were situated in the lower portion of the pons. The association of urgent cardiac and respiratory symptoms would be indicative of hemorrhage into the pons. I presented the rare specimen of a case of hemorrhage bilaterally into the pons and into one crus cerebri, this winter before the Pathological Society of Philadelphia, and which I will have the pleasure of showing to the Section. The mixed symptoms resultant from such a lesion, it would seem to me, make diagnosis quite impossible.

Hemorrhage into the spinal cord high up, would be apt to occur in specific cases and the Brown-Séquard syndrome would follow. Hemorrhage into the membranes into the cord would be associated with large paresthesia or pain distributed to the periphery of the nerves from the segment of the cord encroached upon, and in my experience, not the most difficult for diagnosis; as shown in the case seen with Professor Rodman, this winter, where diagnosis has been confirmed, I take it, by the constant improvement in the case through electric treatment, massage and rest, to quite complete restoration of the paraplegia sequent upon pressure in the lumbar cord, due to a fall down an elevator shaft. Trauma, too, is apt to be a point gotten in the history of such cases. But it is not my province to go in for discussion of disease of the spinal cord.

In the above cursory way, the writer has attempted to give the salient features that have come to his observation for actual determination of one of the most difficult neural affections within the cranium or spinal canal to positively differentiate.

DISCUSSION.

Dr. Hugh T. Patrick, Chicago—I simply wish to say a word in reference to the mystery as to why hemorrhage of the brain comes with peculiar frequency at night, while the patient is asleep and there is no increase of arterial tension. Like the old question, why is it that a vessel nearly filled with water into which a fish is introduced weighs just the same as it did before, the explanation is, that it does not. Cerebral hemorrhage does not occur with peculiar frequency during the night or while people are asleep. That was a theory which was asserted prematurely and it has been disproven a number of times. The statistics gathered by Dana and others show that cerebral hemorrhage does not occur with especial frequency at night. Thrombosis, on the other hand, occurs more frequently at night. I will not take up any more time by discussing the theory of neuron contraction, to which Dr. Pearce referred, as it would be a pure waste of cerebral activity. The theory of neuron contraction never had a single solitary basis upon which to rest.

Dr. F. W. Langdon, Cincinnati—I indorse what Dr. Patrick has said about the infrequency of cerebral hemorrhage at night. It has been my custom, in the course of my teaching, to refer to this as one of the differential points between cerebral hemorrhage and thrombosis. The latter occurs with diseased blood vessels and low blood pressure, while the hemorrhage occurs with weak blood vessels and high pressure. Gowers has also called attention to the fact that the state of the pulse, as indicating low blood pressure, points to thrombosis, while a high tension pulse—not necessarily a high rate—indicates hemorrhage.

I regard this as an exceedingly important point to take note of—both in diagnosis and treatment.

Dr. John Punton, Kansas City—Dr. Pearce, in his paper, failed to mention coma as an important symptom of cerebral hemorrhage. The longer the coma lasts, the less are the patient's chances of recovery. A study of this symptom has also an important bearing upon the surgical aspect of cerebral hemorrhage. The symptoms of cerebral hemorrhage vary considerably, depending upon the seat of the lesion; the diagnosis in some cases being very difficult, while in others quite easy. Another point to which I desire to call attention is that cerebral hemorrhage now occurs much earlier in life than formerly. The text-books teach that it is a disease of beyond middle life, usually coming on between 50 and 60. I am rather inclined to think that nowadays it not infrequently is seen during the active period of life. I can recall several cases in patients between the age of 30 and 35 years.

Dr. W. A. Jones, Minneapolis—I had hoped that Dr. Pearce would enter more into detail regarding the differential diagnosis between the three conditions of cerebral hemorrhage, embolism and thrombosis. The most puzzling cases to me are those of diseased arteries, without hemorrhage. In many such I have been led to suspect hemorrhage, only to find a hardened, thick blood vessel or an obstructed blood vessel. I agree with Dr. Punton that cerebral hemorrhage is now observed more frequently early in life. Thrombosis, on the contrary, is more common in later life. The treatment of the three conditions is decidedly different, and for that reason we should endeavor to make the differential diagnosis.

Dr. E. G. Carpenter, Columbus—A number of cases of ingravescent hemorrhage have come under my observation during the past year, and I hoped to hear more on that subject. I have in mind particularly one case where the postmortem revealed a very interesting state of affairs: The patient was a young man, about 30, in excellent circumstances. He grew dissipated in his habits and in the course of a debauch he fell, receiving a severe injury of the head. He was brought to our institution, in Columbus, for inebriety, and kept under careful observation. He developed no particular symptoms at first, but on the tenth day after the receipt of his injury he died suddenly with all the characteristic symptoms of apoplexy. During the three days preceding his death it had been noticed that he was apathetic and drowsy. At the autopsy the entire right hemisphere was found covered with a large thick clot. This case illustrates the fact that in some instances of the ingravescent form of cerebral hemorrhage the tissues may become very tolerant to the presence of a foreign body, and the hemorrhage may grow to large dimensions without causing many or severe symptoms.

Dr. Pearce, in reply—Most of the cases of cerebral hemorrhage that have come under my observation have occurred at night. In the general symptomatology in which I made the statement of the nocturnal attack prevailing, I included both thrombosis and embolism, which no one will doubt occur more frequently at night. As regards the neuronic theory, I agree with Dr. Patrick that it has not been proven. On the other hand, neither has it been disproven, and I am still inclined to cling to a theory which is fascinating and which explains, in an apparently reasonable manner, the mechanism of some normal and abnormal brain functions.

DANGEROUS HEMORRHAGE AFTER REMOVAL OF ENLARGED TONSILS AND ADENOIDS WITH THE REPORT OF A CASE.

A. C. GETCHELL, M.D.
WORCESTER, MASS.

April 30, 1901, at 5 p.m., I operated, at the Worcester City Hospital, upon Josephine H., a child of 5 years, removing large tonsils and an adenoid growth. The operation was done under ether anesthesia, which at no time was profound, but, on the other hand, just enough was given to keep her beyond the border line of consciousness. The tonsils were removed first and when the hemorrhage, which was rather profuse, but not alarming, had ceased the adenoid growth was removed. The tonsils were removed with a guillotine and the adenoid with forceps and curette. The bleeding promptly stopped, the recovery from the anesthesia was satisfactory and I left the hospital with a sense of relief that an operation that had caused me some anxiety was successfully completed.

At 7 o'clock I received an urgent call to come to the hospital. Much nausea had followed the ether, and previous to my coming the child had vomited a fluid resembling fresh blood at five different times, and about two ounces each time. She had been very thirsty and begged for ice constantly. She had also been very restless and tossed from one part of the bed to another, throwing her arms about and kicking off the bedcloths. The loss of blood, great thirst, restlessness, sighing respiration and failing pulse alarmed the attendants and I was called.

When I saw her bleeding had stopped. The throat had been examined, but no bleeding points were found, and I did not disturb her for further examination. She was greatly bleached, her lips were colorless, ears waxy and pulse very rapid and thready. To insure freedom from disturbing influences, she was put into a separate room under the care of a special nurse. At 8.30, from two to three ounces of dark-brown vomitus, mixed with much blood-clot, was emitted. This did not have the bright character of the former vomitus. The thirst was now intense. At 9, the pulse was 160, the restlessness had increased and delirium had developed, the hallucination being a glass of water on the floor. At 10 o'clock, no radial pulse could be felt, but, with the stethoscope, the heart-beats were found to be 192 per minute. The panting respiration was often interrupted by sighs and the child had lost all interest in her surroundings, although the restlessness was as marked as ever. At this time an enema was given, consisting of the following:

℞.	Albumin water	℥ss
	Bovinine	ʒ 3/4
	Peptonized milk	℥i
	Pinch of salt,	
	Dover's powder	gr. iiss

This was retained.

At 11, the pulse was 180 and a faint flickering could be felt at the wrist. At midnight, however, the pulse had not continued to improve, it being 184, and it was decided to administer a salt solution subcutaneously. The solution was made of common salt and water by adding to a pint of water, made sterile by boiling, a dram of salt. This was reboiled to prevent the deposit of a sediment. The solution was then placed in a glass bottle, with a cotton stopper, and again sterilized in the oven. The apparatus for administration consisted of a glass cylinder holding eight ounces, drawn to a tube at its lower end, to which was attached a rubber tube; to the distal end of this was attached the hypodermic needle. To keep the fluid at the proper temperature the rubber tube was run through a glass tube around which was laid a water-bag filled with hot water. The fluid was forced into the tissues by gravity.

Six ounces of the salt solution were injected under the skin, inside the inferior angle of the scapula, and in half an hour it was entirely absorbed. The effect on the pulse was striking. At 1 a.m. it was plainly counted at the wrist, beating at 160. Besides this injection, Jacobi's mixture was started at midnight. This was given by mouth and consisted of

℞.	Barley water	℥iv
	Brandy	ʒii
	White of one egg,	
	Salt and sugar.	

It was given in doses of ʒii every fifteen minutes, *which meant a teaspoonful of brandy every two hours.*

At 1 o'clock, twenty minims of elixir of chloralimid was given by mouth. At 2, the pulse was 160 and the nutrient enema was repeated. At 3, she vomited two ounces of a bright-red fluid mixed with blood-clots. The pulse was 160. Four and one half ounces of salt solution was injected below the other scapula. At 4, the pulse was 176. At 5, the pulse was 160, and the nutrient enema was repeated. This was followed by undisturbed sleep for twenty minutes. She made no objection to the enemata. At 6, the pulse was 160. At 7, it was 152. Ten and one-half ounces of salt solution was given, and at 8 o'clock the pulse had fallen to 140. At this time Jacobi's mixture, which had been given during the night every fifteen minutes, or as near that as possible, without awakening the child, was omitted, and brandy 20 minims, with sulphate of strychnia, 1/120 gr., was administered every two hours.

The child was kept in the hospital for about a week. She was fed with great care and very closely watched and made steady progress to recovery.

This patient I had not seen previous to the time set for the operation, the arrangements having been made over the telephone, by her father, who said a physician had seen the child and advised operation. She was a delicate-looking child, frail, with transparent skin and large eyes, and when I saw her I was quite taken aback, and for some minutes tried to find with myself some excuse for postponing or modifying the operation.

In such a case four courses suggest themselves: 1. Postpone operation and endeavor to get the child in better condition. 2. Remove the tonsils without anesthetic, paying no attention to the adenoid. 3. Remove the tonsils under an anesthetic and if the bleeding is slight and an adenoid is present remove it also. 4. Do the whole operation, even if a considerable amount of blood is lost in the tonsillotomy.

The last course, the one contrary to my usual practice and against my judgment, is the one I pursued.

Ingravescent hemorrhage and pachymeningitis interna hæmorrhagica have some points in common which are confusing in diagnosis. In both there is apt to be no loss of consciousness; although in the former there is less likelihood of rise of temperature, while in the latter there is elevation of the temperature curve to 102 or 103 or more degrees F., but of irregular type and associated with rather severe pain in the head. Then the spasticity which would occur from cortical irritation from pachymeningitis, would be the positive point as against hemorrhage in the external capsule.

Another differential point in diagnosis between ingravescent hemorrhage and subcortical tumor in the motor area, is to be made in some cases. The history of the case would be important as bearing upon this subject, as well as the examination of the eye grounds where optic neuritis would be present and of high grade in the case of tumor; it almost never being present in the slow hemorrhage, since the neuritis would not have time to develop at the moment of examination.

Hemorrhage into the crus cerebri would be told by the irregularity of symptoms in the first place, and secondly from the alternate hemiplegia following and generally associated with some sensory loss on the hemiplegia side and accompanied by paralysis of the oculomotor nerve on the same side.

Hemorrhage into the pons is very difficult of determination but would be told by critical examination for a crossed paralysis affecting the face on the same side, as hemiplegia in the case of hemorrhage into the upper portion of the oblongata; or secondly, of the face on the same side, if the hemorrhage were situated in the lower portion of the pons. The association of urgent cardiac and respiratory symptoms would be indicative of hemorrhage into the pons. I presented the rare specimen of a case of hemorrhage bilaterally into the pons and into one crus cerebri, this winter before the Pathological Society of Philadelphia, and which I will have the pleasure of showing to the Section. The mixed symptoms resultant from such a lesion, it would seem to me, make diagnosis quite impossible.

Hemorrhage into the spinal cord high up, would be apt to occur in specific cases and the Brown-Séquard syndrome would follow. Hemorrhage into the membranes into the cord would be associated with large paresthesia or pain distributed to the periphery of the nerves from the segment of the cord encroached upon, and in my experience, not the most difficult for diagnosis; as shown in the case seen with Professor Rodman, this winter, where diagnosis has been confirmed, I take it, by the constant improvement in the case through electric treatment, massage and rest, to quite complete restoration of the paraplegia sequent upon pressure in the lumbar cord, due to a fall down an elevator shaft. Trauma, too, is apt to be a point gotten in the history of such cases. But it is not my province to go in for discussion of disease of the spinal cord.

In the above cursory way, the writer has attempted to give the salient features that have come to his observation for actual determination of one of the most difficult neural affections within the cranium or spinal canal to positively differentiate.

DISCUSSION.

Dr. Hugh T. Patrick, Chicago—I simply wish to say a word in reference to the mystery as to why hemorrhage of the brain comes with peculiar frequency at night, while the patient is asleep and there is no increase of arterial tension. Like the old question, why is it that a vessel nearly filled with water into which a fish is introduced weighs just the same as it did before, the explanation is, that it does not. Cerebral hemorrhage does not occur with peculiar frequency during the night or while people are asleep. That was a theory which was asserted prematurely and it has been disproven a number of times. The statistics gathered by Dana and others show that cerebral hemorrhage does not occur with especial frequency at night. Thrombosis, on the other hand, occurs more frequently at night. I will not take up any more time by discussing the theory of neuron contraction, to which Dr. Pearce referred, as it would be a pure waste of cerebral activity. The theory of neuron contraction never had a single solitary basis upon which to rest.

Dr. F. W. Langdon, Cincinnati—I indorse what Dr. Patrick has said about the infrequency of cerebral hemorrhage at night. It has been my custom, in the course of my teaching, to refer to this as one of the differential points between cerebral hemorrhage and thrombosis. The latter occurs with diseased blood vessels and low blood pressure, while the hemorrhage occurs with weak blood vessels and high pressure. Gowers has also called attention to the fact that the state of the pulse, as indicating low blood pressure, points to thrombosis, while a high tension pulse—not necessarily a high rate—indicates hemorrhage.

I regard this as an exceedingly important point to take note of—both in diagnosis and treatment.

Dr. John Punton, Kansas City—Dr. Pearce, in his paper, failed to mention coma as an important symptom of cerebral hemorrhage. The longer the coma lasts, the less are the patient's chances of recovery. A study of this symptom has also an important bearing upon the surgical aspect of cerebral hemorrhage. The symptoms of cerebral hemorrhage vary considerably, depending upon the seat of the lesion; the diagnosis in some cases being very difficult, while in others quite easy. Another point to which I desire to call attention is that cerebral hemorrhage now occurs much earlier in life than formerly. This case illustrates the fact that in some instances of the ingravescent form of cerebral hemorrhage the tissues may become very tolerant to the presence of a foreign body, and the hemorrhage may grow to large dimensions without causing many or severe symptoms.

Dr. Pearce, in reply—Most of the cases of cerebral hemorrhage that have come under my observation have occurred at night. In the general symptomatology in which I made the statement of the nocturnal attack prevailing, I included both thrombosis and embolism, which no one will doubt occur more frequently at night. As regards the neuronic theory, I agree with Dr. Patrick that it has not been proven. On the other hand, neither has it been disproven, and I am still inclined to cling to a theory which is fascinating and which explains, in an apparently reasonable manner, the mechanism of some normal and abnormal brain functions.

DANGEROUS HEMORRHAGE AFTER REMOVAL OF ENLARGED TONSILS AND ADENOIDS WITH THE REPORT OF A CASE.

A. C. GETCHELL, M.D.
WORCESTER, MASS.

April 30, 1901, at 5 p.m., I operated, at the Worcester City Hospital, upon Josephine H., a child of 5 years, removing large tonsils and an adenoid growth. The operation was done under ether anesthesia, which at no time was profound, but, on the other hand, just enough was given to keep her beyond the border line of consciousness. The tonsils were removed first and when the hemorrhage, which was rather profuse, but not alarming, had ceased the adenoid growth was removed. The tonsils were removed with a guillotine and the adenoid with forceps and curette. The bleeding promptly stopped, the recovery from the anesthesia was satisfactory and I left the hospital with a sense of relief that an operation that had caused me some anxiety was successfully completed.

At 7 o'clock I received an urgent call to come to the hospital. Much nausea had followed the ether, and previous to my coming the child had vomited a fluid resembling fresh blood at five different times, and about two ounces each time. She had been very thirsty and begged for ice constantly. She had also been very restless and tossed from one part of the bed to another, throwing her arms about and kicking off the bedcloths. The loss of blood, great thirst, restlessness, sighing respiration and failing pulse alarmed the attendants and I was called.

When I saw her bleeding had stopped. The throat had been examined, but no bleeding points were found, and I did not disturb her for further examination. She was greatly bleached, her lips were colorless, ears waxy and pulse very rapid and thready. To insure freedom from disturbing influences, she was put into a separate room under the care of a special nurse. At 8.30, from two to three ounces of dark-brown vomitus, mixed with much blood-clot, was emitted. This did not have the bright character of the former vomitus. The thirst was now intense. At 9, the pulse was 160, the restlessness had increased and delirium had developed, the hallucination being a glass of water on the floor. At 10 o'clock, no radial pulse could be felt, but, with the stethoscope, the heart-beats were found to be 192 per minute. The panting respiration was often interrupted by sighs and the child had lost all interest in her surroundings, although the restlessness was as marked as ever. At this time an enema was given, consisting of the following:

℞.	Albumin water	℥ss
	Bovinine	ʒ 3/4
	Peptonized milk	℥i
	Pinch of salt,	
	Dover's powder	gr. iiss

This was retained.

At 11, the pulse was 180 and a faint flickering could be felt at the wrist. At midnight, however, the pulse had not continued to improve, it being 184, and it was decided to administer a salt solution subcutaneously. The solution was made of common salt and water by adding to a pint of water, made sterile by boiling, a dram of salt. This was reboiled to prevent the deposit of a sediment. The solution was then placed in a glass bottle, with a cotton stopper, and again sterilized in the oven. The apparatus for administration consisted of a glass cylinder holding eight ounces, drawn to a tube at its lower end, to which was attached a rubber tube; to the distal end of this was attached the hypodermic needle. To keep the fluid at the proper temperature the rubber tube was run through a glass tube around which was laid a water-bag filled with hot water. The fluid was forced into the tissues by gravity.

Six ounces of the salt solution were injected under the skin, inside the inferior angle of the scapula, and in half an hour it was entirely absorbed. The effect on the pulse was striking. At 1 a.m. it was plainly counted at the wrist, beating at 160. Besides this injection, Jacobi's mixture was started at midnight. This was given by mouth and consisted of

℞.	Barley water	℥iv
	Brandy	ʒii
	White of one egg,	
	Salt and sugar.	

It was given in doses of ʒii every fifteen minutes, which meant a teaspoonful of brandy every two hours.

At 1 o'clock, twenty minims of elixir of chloralimid was given by mouth. At 2, the pulse was 160 and the nutrient enema was repeated. At 3, she vomited two ounces of a bright-red fluid mixed with blood-clots. The pulse was 160. Four and one half ounces of salt solution was injected below the other scapula. At 4, the pulse was 176. At 5, the pulse was 160, and the nutrient enema was repeated. This was followed by undisturbed sleep for twenty minutes. She made no objection to the enemata. At 6, the pulse was 160. At 7, it was 152. Ten and one-half ounces of salt solution was given, and at 8 o'clock the pulse had fallen to 140. At this time Jacobi's mixture, which had been given during the night every fifteen minutes, or as near that as possible, without awakening the child, was omitted, and brandy 20 minims, with sulphate of strychnia, 1/120 gr., was administered every two hours.

The child was kept in the hospital for about a week. She was fed with great care and very closely watched and made steady progress to recovery.

This patient I had not seen previous to the time set for the operation, the arrangements having been made over the telephone, by her father, who said a physician had seen the child and advised operation. She was a delicate-looking child, frail, with transparent skin and large eyes, and when I saw her I was quite taken aback, and for some minutes tried to find with myself some excuse for postponing or modifying the operation.

In such a case four courses suggest themselves: 1. Postpone operation and endeavor to get the child in better condition. 2. Remove the tonsils without anesthetic, paying no attention to the adenoid. 3. Remove the tonsils under an anesthetic and if the bleeding is slight and an adenoid is present remove it also. 4. Do the whole operation, even if a considerable amount of blood is lost in the tonsillotomy.

The last course, the one contrary to my usual practice and against my judgment, is the one I pursued.

I did it because the child was there and the parents expected the operation to be done, and, furthermore, because it was evident that the child needed the help that would come from the removal of very large tonsils. The adenoid was removed because I felt that the child might not be brought for a subsequent operation, and, therefore, this operation would be incomplete; to her disadvantage and my discredit.

However, I followed the operation through with much caution, both as to the use of the anesthetic and the removal of the growths. The hemorrhage from the tonsillotomies was profuse, but did not alarm me. I had seen much severer ones with no untoward aftereffect and I did not feel that the risk was great; but I reckoned without my host.

The operative hemorrhage alone probably would not have produced alarming symptoms, neither would the poor recovery from ether, but she was of such a frail constitution that the weakness brought about by both these causes induced the post-operative hemorrhage, which was serious and bade fair to be fatal. One or two of the obstacles to recovery she might have overcome, but the three were too much for her, and it seems she surely would have died but for the prompt and skilful treatment she received. She had all the advantages of a well-equipped institution, and particularly of the services of a peculiarly capable house physician, Dr. W. W. McKibben, to whom I am indebted for many of these notes.

This experience confirms me in the conviction—that under the age of 5 years one should do the complete operation for removal of tonsils and adenoids with a great deal of caution, and where the tonsils are very large and the child is delicate and anemic, the complete operation under ether should not be attempted. The tonsils can and should be removed, but this can be done with no anesthesia or with a few whiffs of chloroform. The incompleteness of the operation should be explained to the parents and a future removal of the adenoid growth, under an anesthetic, should be considered and planned. Indeed, after the gain in health that usually follows the removal of the tonsils this becomes a safe proceeding.

In the consideration of this topic it would be proper to discuss the methods of operating that have been proposed to minimize hemorrhage. Some of them I have tried, others have promised such slight advantages that I have not tried them, and I will not take time for other enumeration.

For young children, I find no instrument is so generally useful as the tonsillotome for the tonsils, and the forceps, curette and finger-nail for the removal of adenoid growths. The choice is to be exercised not so much in the selection of instruments and methods, as in careful observation of the patient and the selection of proper time and conditions for the operation.

NOTES ON ONE HUNDRED AND FIFTY CASES OF SMALLPOX IN PRIVATE PRACTICE.

ALBERT SOILAND, M.D.
LONG LEAF, LA.

There exists some diversity of opinion among members of our profession regarding the true nature of the disease which has been rather epidemic in some sections of our country during the last few years, and which has been termed by the various writers variola, modified smallpox, pseudo-smallpox, varicella, Cuban itch, elephant itch, Philippine rash, etc. It is true that the great majority of physicians recognize this disease as genuine smallpox; yet there are a number of careful observers who will not admit that such is the case, but who insist that this is a new unclassified disease; others again hold that it is an unusually severe type of chickenpox.

During the past twelve months I have had the opportunity to observe and treat 150 cases of this disease, as they occurred in private practice, principally among the negroes, in Central Louisiana, and I do not hesitate to state that these cases were genuine smallpox and could not be confounded with any other disease. I also saw a number of cases of variola in Northern Mexico three years ago, just before the disease became general throughout the United States, and these cases were identical in type with my recent ones.

Clinically, the course of my cases followed that laid down in the text-books to a large extent, with the exception that the secondary fever was low in most of the patients. It was, however, high in a number and altogether absent in a few of the extremely mild cases.

The onset was usually sudden, with high temperature, gastric disturbances and pains in the back. This last symptom proved to be quite a diagnostic point in my cases, as it would not yield to medication before the eruption appeared. The period of eruption followed also the typical course, papule, vesicle, pustule and crust, the vesicles becoming distinctly umbilicated in nearly every case, and the four stages occurring in cyclic order; not as in varicella where all stages of eruption may be found at one time. In 34 of my cases the eruption was confluent, no part of the body being exempt from attack. Here the pustules coalesced, forming large patches over the entire body, making a picture horrible to behold, and a condition almost unbearable for the poor sufferers, who can not be comfortable in any position.

During desquamation, which is prolonged here owing to the deepest structures of skin being involved, large casts are thrown off from the four extremities. This is a condition which never exists in varicella as far as I can learn and I have never heard of the eruption in varicella appearing upon the plantar surface of the feet and the palmar surface of the hands. There was delirium present in all these severe cases.

The course of the disease ranged from three to eight weeks, according to the intensity of eruption and the amount of constitutional disturbance [illegible] case. It is true that a number of [illegible] suffered no further inconvenience than that occasioned by the amount of eruption present, and felt fairly at ease after eruption appeared. In all of the confluent and in a few of the discrete cases, the prostration was very marked, and as stated, the disease followed the typical orthodox course. It was impossible to determine by the prodomal symptoms whether a discrete or confluent case would follow, as in a number of instances the most severe prodromes would be followed by a mild eruption and vice versa. The disease seemed to have a selective preference for the negroes, probably on account of their careless personal hygiene, although a number of whites were also attacked.

One of my cases proved fatal and that was the only one with a hemorrhagic type of the disease I have seen. This was a young mulatto about 25 years old who had suffered from arrhythmia and a cardiac neurosis for several years. He contracted smallpox a few days after arriving in our settlement, and died on the fourth morning after onset. In his case the hemorrhage took place in the papules before they were mature, the skin resembling that of erysipelas, being tense and shiny.

As long as our knowledge of the specific poison of smallpox is lacking, we can only direct our attention to the treatment of symptoms, and prophylaxis. In my cases I practiced isolation as much as possible, used the coal tar derivative, acetanilid, citrophen, thermol, etc., for the early symptoms with varying success. For the constitutional disturbances a morning saline and quinia and strychnia t. i. d., together with milk and soft-food diet were given. Calcium sulphid, which has been lately recommended as a specific, yielded very indifferent results, although faithfully used in about one-half of the cases. In fact, the only two cases of general furunculosis which developed after patients had recovered from the effects of the smallpox eruption occurred where this drug had been exhibited.

For the eruption various washes and ointments were applied, as carbolic acid and bichlorid solutions, boric acid, glycerin and ichthyol in different proportions. That which gave most satisfaction was a 5 per cent. lotion of liquor carbonis detergens in water; the skin surface was kept moist with it continually. This seemed to control the secondary fever and render the eruption less irritating.

The so-called characteristic odor of variola becomes very marked as pustulation advances, and is, of course, due to the necrotic processes in the skin. This unpleasant odor is masked by keeping body moistened with the detergent solution named or carbolic acid.

The one point which I wish to emphasize, however, and which I think of paramount importance, is the fact that not one of the cases in my district had been vaccinated, and that not one person who was successfully vaccinated contracted the disease. The significance of this statement will be realized when we consider that these people were very careless about exposing themselves, and would mingle daily with those who were already stricken, and when not actually watched, would spend some time visiting houses where probably five or six patients were in bed with smallpox. About 350 persons in all were vaccinated, and not a single one of these contracted the disease, although they were all exposed at different times.

In this connection one peculiarity was noticed which happened altogether too frequently to be due to mere chance. When one member of a family came down with smallpox I would immediately vaccinate the other members, one or two of whom would not react, and these would subsequently develop smallpox, but at a comparatively late period. Often in a family of five or six the father would take sick first. If the others had not already been vaccinated they would then submit to it—usually under protest—and within a week two or three would respond favorably, but one or two would fail to take. I would then revaccinate these as often as practicable, but would get no reaction. Now, after several weeks, and when the other members of the family had recovered, those who had failed to react to the several vaccinations would invariably come down with smallpox. I can not say whether the vaccinations in these instances retarded the outbreak of the disease, or whether the personal resistance against it was the factor.

A SATISFACTORY OPERATION FOR CERTAIN CASES OF RETROVERSION OF THE UTERUS.

J. CLARENCE WEBSTER, M.D.
Professor of Obstetrics and Gynecology, Rush Medical College, affiliated with the University of Chicago; Obstetrician and Gynecologist, Presbyterian Hospital.
CHICAGO.

During the past year I have carried out the following procedure in a number of cases where operative interference has been deemed advisable for retroversion of the uterus.

The patient being in the Trendelenburg position, the abdomen is opened, adhesions are separated and other pathologic conditions, which may be present, attended to. The fundus of the uterus is elevated and pushed forward. A small hole is then made through the broad ligament on one side under the utero-ovarian ligament near the uterus. Through it a pair of forceps is passed from behind in order to grasp the round ligament about an inch from its uterine end. The latter is then pulled through the broad ligament in a double fold. It is carried across the back of the uterus a short distance above the utero-sacral ligaments and is then stitched in this position with chromic catgut. A similar procedure is carried out on the other side, the second round ligament being stitched to the back of the uterus above or below the first one or crossing it. The amount of overlapping of the round ligaments depends upon their length and laxity.

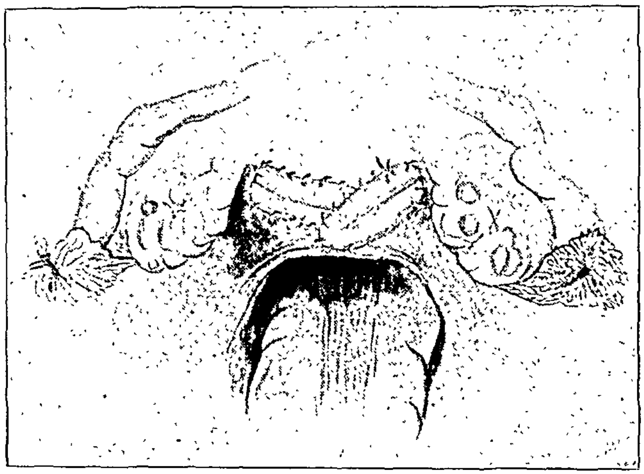

Diagram representing the round ligaments doubled up, drawn through the broad ligaments and stitched to the posterior surface of the uterus above the utero-sacral ligaments.

Each ligament is also stitched to the edge of the hole in the broad ligament. As a result of this operation, the round ligaments are much shortened and through their new attachment to the posterior and lower part of the uterus, act both in elevating the uterus as a whole and in preventing it from returning to its retroverted position. The ovaries are also elevated. No raw surface is produced on which adhesions can form. No new ligament is formed to act as a possible cause of intestinal obstruction and of trouble in pregnancy and labor. The normal range of uterine movements is not materially altered. There is no possibility of any interference with pregnancy and labor.

The operation can be performed equally well by vaginal section. It seems, therefore, to me to be more advantageous than the other operative procedures commonly employed in the treatment of retroversion of the uterus.

ARE ATOMS REAL ENTITIES?

At the opening of the 71st annual session of the British Association for the Advancement of Science, which met in Glasgow last September, President Rücker of the University of London devoted his address to an interesting discussion of the present atomic theory of the constitution of matter. Through the century just ended, a century of wonderful progress in chemical and physical knowledge, three grand conceptions have dominated the so-called physical sciences as distinct from the biological, 1, that matter is made up of separate particles—Dalton's fruitful and comprehensive theory of the existence of atoms; 2, that heat is due to movement among these particles, and 3, that there is an all-pervading subtle medium called ether. While these conceptions have grown in strength with each succeeding decade, they have not been blindly accepted without question. Especially during recent years have voices been raised against their universal acceptance, and the opinion has been expressed that the atomic theory and the theory of the existence of ether have served their purpose. It may be freely admitted that the view that matter is consituted by aggregations of separate particles has been useful in helping us to get some sort of understanding of the properties of matter in the past, but we are urged not to forget that these units are simply speculative and not objective and real. The terms "atoms" and "ether," useful and convenient fictions, answer the purpose of working drawings which though different from material reality yet help us to gain an insight into its arrangement and its properties, and to codify observed facts and laws. But the working model is probably very much unlike the real thing.

At the present time chemistry teaches the existence of about 100 different elemental forms of matter. Their weight-relationships to one another are, however, suggestively near multiples of the same number, and this resemblance in relative weight coincides with other resemblances, so that chemistry is pervaded by an indistinct belief that there is a common element which is the substratum of all kinds of matter. This dream that matter of all kinds will some day prove to be fundamentally the same has survived many shocks. Atmospheric air, carbonic dioxid and other mixtures and compounds may be broken up into several distinct, tangible entities, and the question is, can these gases be broken up further into molecules and atoms whose very motion we may be able to trace by actual, tangible proof? Of course, matter in bulk appears continuous, but how are we to explain the phenomena of diffusion and expansion and heat if all substances are perfectly uniform in all their parts? Air diffuses into water, and water penetrates into air, and the rights of way for the one through the other apparently exist. Rücker cites a recent classical experiment by Sir W. Roberts Austen, who placed pieces of gold and lead in contact at a temperature of 18 C. "After four years the gold had traveled into the lead to such an extent that not only were the two metals united, but, on analysis, appreciable quantities of the gold were detected even at a distance of more than 5 millimeters from the common surface, while within a distance of three-quarters of a millimeter from the surface gold had penetrated into the lead to the extent of 1 oz. 6 dwt. per ton." A simple, satisfactory explanation of such phenomena is found in the conception that matter consists of separate particles in motion, "which can penetrate into the spaces between the corresponding parts of surrounding bodies." There seems to be no limit to the expansion of matter, such as a gas, but it is certainly inconceivable that a continous material present in every part of a space can also be present in every part of a space a million times as great. Different kinds of light all travel at the same speed in interplanetary space, but at different rates in matter—a fact also explained by the coarse-grainedness of matter. Being forced to accept the particulate nature of matter what if anything do we know of the properties of these particles! What we do know of the properties of matter we have learned through the forces acting on our organism. These properties are of the aggregate of particles composing matter and as long as we are unable to detach a molecule or an atom we are not able to learn anything of its properties in isolation. Emerson has said in his essay on farming that "you can not detach an atom from its holdings, or strip off from it the electricity, gravitation, chemic affinity, or the relation to heat and light, and leave the atom bare," and such seems to be the case even to-day.

The question of the existence of molecules and atoms may be regarded as settled, the outstanding difficulties relating wholly to the nature and constitution of the granules. It has been said that every great advance in chemistry in the last 90 years finds its interpretation in Dalton's theory of atoms, and Rücker emphasizes strongly the fact that the atomic theory imparts a unity to all physical science. He likens a crowd of molecules to a fog and recounts the experiments of Wilson and J. J. Thomson in causing vapor to condense upon the molecules of highly rarefied gas until they become magnified into a visible mist. Fine dust facilitates greatly the production of fog, and these investigators show that electrified particles may act in a similar manner as nuclei for the condensation of vapor. Such electrified particles result from the breaking up of molecules into ions. Indeed, the atomic theory has received strong support from the recent studies of electrolytic dissociation. J. J. Thomson's recent work on cathode-ray phenomena has led him to results that indicate even the divisibility of atoms into negatively electrified corpuscles.[1]

PROGNOSIS.

The soothsayers of old were looked upon with awe when by flight of birds, by falling star or by weird incantations they foretold the future. When to-day by examination of the tongue or pulse, by throwing a light into the eye so that he may inspect the eye-grounds, by listening to the working of the lung or heart, or by the study of secretions in the test-tube and under the microscope, the physician pronounces upon the fate of his patient, the same feeling of mystery comes over the listener, and the same unconscious homage is done the superior being who can peer into the future as was accorded the soothsayer. Much more credit is often given to a physician for a correct prognosis than for the acute diagnosis or skilled treatment that underlies his statement as to the course of the disease and its termination. He predicts that on a certain day the crisis will occur or the rash will disappear, or convulsions may take place. With wonder the laity see what was foretold come to pass and their amazement is great and the physician is credited with insight almost supernatural. Even though the doctor in his helpless ignorance may say that he can not tell what the result will be, that the patient may recover and live to a ripe old age or may die within twenty-four hours, he is accorded, perhaps unmerited, praise for his ability and the question is discussed as to how the doctor could tell such and such would happen.

The ability to make a prognosis depends on no mysterious or occult power, on no supernatural gift, but on study and experience. The natural history of disease, the effect of treatment, and an accurate knowledge of the existing conditions present in the given case must be known. This enables the physician to take a comprehensive view of the case and to hazard something more than a shrewd guess. A prognosis may be based largely upon an accurate knowledge of statistics, yet each case has to be considered by itself, the surroundings of the patient, the virulence of the disease process, the resisting power of the invalid, his individual peculiarities, and the condition of all the vital organs. It is here that the physician of broad education, of wide experience and of shrewd observation is often enabled to foretell the future to the upsetting of statistical tables and the amazement of the friends of the patient, and often of other physicians.

While the ability to make an accurate prognosis depends to a large extent upon actual experience, it must be remembered that this power is not entirely a natural gift, or a mysterious power granted to the few, but that it is just as much the result of reading, study, observation at the bedside and in the deadhouse, and of logical reasoning as is a scientific diagnosis or rational therapy.

VACCINATION AND SMALLPOX.

The *Popular Science Monthly* for October contains an article by Professor J. Nevins Hyde on the late or still-present smallpox epidemic in this country. He shows first how massing together of people, who thus lose their customary adaptation to environment, creates a peril and that this is especially accentuated when the assemblage is the form of camps and in time of war. War and pestilence are twin brothers, but they do not always appear side by side. More often pestilence follows war, and he illustrates this from our own history—the skin diseases so abundant after the Revolution, the cholera epidemic following the Mexican war, and the prevalence of typho-malarial fevers after the Civil war. Our late Spanish war is no exception; it has introduced into our country an epidemic of smallpox sweeping from the Eastern and Southern portion to the Pacific and involving all sorts and conditions of men. It came also in a form that has troubled the diagnostician and for this reason its range has been the more extended, the mildness of the malady in most cases leading to neglect of precautions and consequent spread of the contagion.

The cause of the mildness of the disease is explained by Hyde by the immunity conferred by vaccination through generations, an immunity conferred even in unvaccinated by inheritance, which he thinks must be admitted, not merely as a logical sequence of laboratory experiments, but from clinical facts. "Not the sins alone of the fathers, but some of the safeguards, are visited upon the children." The germs were brought from the Spanish hotbeds of smallpox by our vaccinated soldiers and were thus attenuated in virulence. It has been largely an epidemic of modified varioloid, but capable of producing in virgin soil the typical variola, as has been shown in many instances. Vaccination, however, while probably as near perfection as a preventive of smallpox as any human means can be, is still not absolutely perfect, and its failures show most plainly in epidemics when those ordinarily resistant to vaccinia become amenable and vaccination may even apparently succeed after or during the developed smallpox itself.

These exceptional facts, however, prove nothing against the rule, and the anti-vaccinationists overlook the signal victories over smallpox of which the general character of the present epidemic is itself an evidence. Hyde shows that, were it necessary to appeal to statistics at this late day to prove the value of vaccination, the experience of Porto Rico alone, where smallpox has been practically stamped out in two years, would be sufficient. She "bombarded us with a filth germ and in revenge we made her clean." His article concludes with the demand that "vaccination should be the seal on the passport of entrance to the public schools, to the voter's booth, to the box of the juryman and to every position of duty, privilege, profit or honor in the gift of either the State or the Nation.

ASTONISHING IF TRUE.

In an editorial notice of an article by Kretzner on the pathology of the Jew, the *British Medical Journal* makes the following astonishing quotation, apparently from Benedikt: "At the present day among orthodox Jews every female is condemned from nativity till the menopause to an uninterrupted series of pregnancies, parturitions and lactations." This is important if true. We have heard much of the remarkable qualities of the Jewish race, but its precocity has never so impressed us before. It is so common for us to see in British publications remarks on our own deficiencies in the use of the English language that we can not think they do not know how to use it over there at its source, or we would believe the editor of our contemporary had made a mistake.

THE TEACHING OF PHYSICAL THERAPEUTICS.

The time is past when the treatment of disease is comprised in the administration of drugs, and to-day more than ever it is recognized that other forces of nature may be so employed as to render valuable therapeutic aid. If evidence of this fact were wanting it could be found in the circumstances that there are at present being published in English and in German, systems of therapeutics in which physical agents especially are discussed, such as heat, light, water, air, electricity, massage, rest, diet, etc. These are subjects, however, to which scant attention has been given in the past in the medical schools and by reason of their great importance it would seem that the time is now ripe for their inclusion in the medical curriculum.

YELLOW FEVER INVESTIGATION BY THE MARINE-HOSPITAL SERVICE.

In a letter to the Secretary of the Treasury, Surgeon General Wyman of the Marine-Hospital Service proposes a plan for the organization of a yellow fever institute under the auspices of his bureau. The members are to be the officers of the Marine-Hospital Service and others specially qualified, who may be invited to assist. The plan includes four sections, each having special topics for its consideration, and each section will be under the direction of one of the bureau medical officers who, with the surgeon general, the director of the hygienic laboratory and a secretary, will constitute a supervising body. There will be bulletins published from time to time as material is afforded by the investigations and "it is believed that the organization will meet with a degree of success warranting its existence." The prime motive for the proposed organization appears to be the demands by commercial interests for the modification of the quarantine laws. The necessity of the regulations heretofore in force against yellow fever infection has been questioned since the publication of the results of the studies of the army surgeons, and the bureau wishes to make a complete study of the subject. Medical men generally are inclined to accept the findings of Drs. Reed and Carroll and their co-workers as final, but there may be a few questions still open as regards the limits of usefulness of quarantine measures. We do not understand that the proposed studies are intended in any way to conflict with the work of other investigators, but rather to confirm them and to definitely establish the practical measures needed to exclude yellow fever from our shores. There is also a broad field of inquiry in regard to yellow fever that is yet to be satisfactorily worked. It is to be hoped that the proposed institute will occupy it profitably.

THE DISPENSARY EVIL.

The Pennsylvania State Medical Society proposes to attack the dispensary abuse in a new way. It asks the state legislature to pass a law requiring all persons seeking aid at dispensaries and other charitable institutions to record their names and addresses over their own signatures, or marks if unable to write, in a book kept for the purpose which shall be open for inspection, and to inflict a penalty upon those who fraudulently receive aid. The plan is certainly simple enough and if made universal by legislative act ought to be effective. Of course, everything would depend upon its faithful execution, and we fear that in the competition for clinical material there may be some chances of failure in this respect. Everything really depends upon the dispensary authorities and to check any possible laches on their part it should be the business of the medical societies on behalf of the profession to inspect the books and see that they do their duty. If this were done by some responsible agent and a sufficient penalty enforced, the charities could do better work and not be, as they sometimes now are, an imposition on the long-suffering general practitioners of our great centers of population. The medical colleges, especially those that might well be spared, would probably have some of their clinics diminished, but the profession as a whole would be better off. It is not the altruism of us as a whole, but the egoism of a few that keeps up these abuses.

LAXITY IN PENSION EXAMINERS.

The Commissioner of Pensions recently sent out to all examining pension boards a circular-letter calling attention to certain abuses. He sent his letters broadcast to avoid laying open to personal attacks those particular boards he had in mind. It appears that there has been in some quarters a serious carelessness, to say the least; twenty applications for example made at once from one section of the country were all certified as cases of heart disease. This aroused suspicion and special examinations by disinterested physicians ordered by the commissioner revealed no heart disease in any of the cases. Other similar experiences led to the dismissal of certain boards and the issuance of this letter. The public generally has a conviction that there is a vast amount of fraud in the pension business, and the publication of such facts as these confirm it. It seems that there are members of our profession who, through mistaken sentimentality or something else, will return a false report or acquiesce without personal attention to the cases in an erroneous diagnosis of another physician or even to the mere statement of the claimant. It is not pleasant to have official evidence of such a fact, but there is no doubt such things have been done. The medical pension examiner who does not realize the fact that he is charged as a public officer to act honorably and honestly in his work, is, to use an expression that means much more than it says, no better than he should be. In short, he is aiding and abetting fraud. There has been either a laxity of professional honor and good morals in his case, or, what is nearly as bad, of competency to perform the work he swears to do.

VOLUNTEER HEALTH INSPECTORS.

The Chicago Health Department has utilized, during the past five years, the services of volunteer health inspectors whose duty was chiefly or largely to go out in the sections occupied by the poorer classes and give instructions as to hygienic needs. Their work was done especially in the hot midsummer months when the sanitary shortcomings are most serious in their effects, particularly to infants and young children. The results are best shown by the fact that the deaths of children under five years of age, since these inspections have been made, are 14,000 less in number than during the preceding five years. Over 10,000 homes have been inspected and many cases of contagious disease without medical attendance were found; a vast amount of insanitary conditions was corrected, largely by the householders themselves at the suggestion of the inspectors. So far as possible, anything like harsh police methods was avoided; the inspectors sought to win the confidence of the people, and generally with success. The inspections have been of special value during the past summer; they have insured better supplies of milk and ice, and have located the origin of many cases of typhoid and prevented other cases from the same. While the call for volunteers was instigated by a reduction of the working force of the department, it seems to have been readily responded to by the physicians of the city, and the results above stated are proofs that the efficiency of the city sanitary service has not been in any way impaired, but rather the contrary. To the physicians who volunteer it has the advantage of bringing them in contact with the people, of extending their acquaintance, and of serving to a certain extent as a clinical course in practical hygiene. What was at first an experiment has passed beyond the experimental stage and proven its value as a health-securing and life-saving procedure. The success in Chicago is a suggestion to other places that have as yet not adopted the plan.

CARELESS REPORTING.

As an example of careless reporting of experiments the following is worthy of mention. In the *British Medical Journal* of September 14 there appears an article giving some interesting observations on the penetration of the skin by the larva of the ankylostoma. The author says: "The experiment upon Dr. Looss is not convincing because he had, as I have said, previously suffered from the presence of ankylostoma in his intestines. He next experimented on a piece of skin removed from a fresh human corpse, and warmed to 99 F.; but this did not show any entry of embryos, possibly because the skin at once became too shriveled up. The next attempt was more successful. It was made upon the leg of a boy, aged 13 years, one hour before the limb was amputated. The leg was thoroughly washed with soap, nail brush, and water, then dried; and then one drop of water containing many larvæ was dropped on the skin and left to itself without being rubbed in. The drop spread out and dried up in ten minutes, and produced no redness of skin. The patient was not asked whether he felt a burning sensation. One hour after the drop came in contact with the leg the limb was amputated, and the suspected skin was at once removed from it and spread out with pins, gradually hardened in alcohol, and then embedded for section cutting, etc." There is nothing out of the way in this to a physician, because he would at once understand that there was some valid cause for the amputation and the opportunity was only utilized for an experiment that caused no suffering. But it should have been so stated. It is just such a report as would be taken up by our friends, the anti-vivisectionists, as evidence that this physician amputated the boy's leg to determine the pathologic question he was investigating. Even if they were aware that the amputation was for reasons not given, it would still probably come under their condemnation; but as it stands we expect to see it added to the list of horrible human vivisections in some future pamphlet attacking the inhuman doctors. One must be most particular how he writes in view of such possibilities.

POLITICS IN STATE INSTITUTIONS.

A beautiful example of the effects of political management of public charitable institutions was afforded recently at the Arkansas State Insane Hospital. The managing board passed a resolution ordering the superintendent to discharge all "alien" employes (nonvoters?) within ninety days and fill their places with Arkansans. The attendants thereupon joined in signing a memorial to the Governor asking for assurances as to the security of their positions. He replied that it was in the discretion of the superintendent to keep them till he could fill their places as directed. The result of this was that they quit work in a body and the Governor was obliged to make a personal visit to the institution and give them the desired assurance before they would return to their duties. It is not surprising that, with the examples about them, the strike should come to be the recourse of hospital attendants, and the serious consequences that might follow are readily imaginable by anyone familiar with asylums. Under the political management existing in many of our state institutions this may come to be one of the possible abuses. When the ideals of the governing authorities are no higher than to make these public charities simply a portion of the political spoil system, the lower officials will also be likely to neglect the humanitarian aspects of their work and we may have strikes for any possible cause, such as the discharge for cause of a popular fellow attendant or the engagement or retention of an unpopular one. When the state officers and managers look on these institutions simply as a means for their own political advancement, the subordinates are not likely to be very altruistic in their ideals or conduct. Hence, this gives rise to the scandals that are so frequent and that afford such welcome material for the sensational newspaper press. The medical profession owes it to itself to start a reform in this matter, to make politicians as well as soldiers respect the neutrality of hospitals. This is needed for our own credit, which has suffered and is still suffering from conditions as they have existed in the past and to a too great extent still exist. We can not begin the work of reform too soon.

LIMIT OSTEOPATHS TO WHAT THEY PROFESS.

Osteopathy, according to its founders and its advocates, is a system of treatment of disease without drugs, and they have had special laws passed in several states for their benefit embodying this idea. In these it is particularly specified that they are not authorized to administer drugs or to perform surgical operations. It has been urged in objection to these laws that they were only a subterfuge to evade the medical practice laws of the state and that the osteopaths would not confine themselves to the methods they profess to exclusively follow. That this is the case is revealed by the evidence in a recent suit in Denver, Colo., where a female professor of osteopathy sued for services rendered and it came out in the trial that she had not confined herself to osteopathic manipulations, but had prescribed medicines and administered treatment which only licensed physicians are entitled to give. The judge, while favoring osteopathy to the extent that he would not allow a non-suit on account of the plaintiff's lack of license, instructed the jury to find for the defendant if it believed she had been prescribing drugs. The case was decided for the defense and appealed by the plaintiff. Our confrères in Denver are, it is understood, taking up the matter vigorously, and a determined fight will be made to prevent this form of quackery from thriving on its illegitimate methods in the state. There is no doubt whatever that osteopathy laws are designed as entering wedges to open up a way to unlimited irregular practice. Consistency is not likely to be regarded by their advocates and beneficiaries; they care little as to the difference between their practice and their professions as long as they can successfully fool the public. While their use of drugs is practically self-stultification, it matters nothing to them provided the money comes in. The outcome of the fight in Colorado will be watched for with interest as the same matter will probably have to be fought over elsewhere. It is well to call the attention of the medical profession generally to the subject and to see that the osteopaths and others of their kind are not permitted to exceed their legal limitations. Every law that has been enacted for their benefit was passed through most positive assurances on their part that only manipulative procedures would be practiced by them in their treatment. Now let us be on guard to keep them to what they profess. If their treatment is limited to manipulation, osteopathy so-called will soon be a thing of the past, or exist only under its true designation, massage.

ENGLISH COMMENT ON THE M'KINLEY CASE.

While it has been a cause of satisfaction that the foreign newspapers, reflecting the sentiments of their readers, have spoken so highly of our late President, there is none the less gratification to us as medical men to read in the foreign medical journals so far received endorsements of the treatment of the case. The *Lancet* says:

> The favorable prognosis which was put forth at first was so far justified that in some cases recovery might have followed, but the issue hardly comes as a surprise. The injuries were terrible, the patient was no longer young, and the circumstances were such as to produce, even in a man of iron courage, the maximum of shock. If we may venture to criticise any portion of the treatment we feel inclined to suggest that the feeding by the mouth was somewhat in excess of that which is usually considered advisable. But while we say this we know that to the brilliant surgeons and experienced physicians around President McKinley's bed there may have been indications for the bolder treatment impossible to be disregarded. In short, on a careful review of the whole case we feel justified in saying that surgery did its best; the sad result is to be ascribed to the lack of vitality of the tissues themselves.

The *British Medical Journal's* comments do not contain even a hint at criticism, and the last part of the quotation below is certainly more pleasing reading than the harsh and uncalled-for criticism in an American medical weekly, referred to last week:

> A large bullet was discharged, with low velocity; instead of a clean wound the result of cleavage, there was a wide channel, with much surrounding bruising and laceration, and sloughing followed. There is no need to assign any influence to a supposed escape of pancreatic secretion or to a poisoned bullet. The mechanical conditions are ample to account for all the disturbance found. Much also seems to have been made in comment by the lay papers of the absence of healing described in the record of the necropsy. Such a lethargy on the part of wounds is, unfortunately, not an infrequent experience in abdominal surgery. In gastro-enterostomy for malignant disease of the pylorus, or in any short-circuiting operations performed in conditions of acute obstruction or of exhaustion resulting from malignant disease, complete absence of reparative power may be observed. One hears the pathologist say that the serous surfaces of the wound "fell apart" when examined, or that there was "no attempt at healing," and so forth. If the bruising of the stomach spread widely from the perforations made by the bullet, it is not idle to suppose that a local and coextensive "stunning," a complete cessation of activity, was also present. In such a condition healing is impossible.
>
> We can only repeat, though perhaps with greater emphasis, as more is now known of the facts, what was said last week as to the conduct of the case. In such a catastrophe operation affords the only hope of relief, and the earlier it is performed the greater the chance of success. Whether a resection of the bruised portion of the stomach would have affected the result we can not, in the absence of exact details, determine; but this we may with confidence assert, that American surgery ranks as high as that of any country in the world, and that in the medical men chosen to attend the late President, America was worthily represented. Success in such a case would have been a triumph, but defeat is not disgrace.

Medical News.

CALIFORNIA.

Street Cuspidors.—Dr. T. J. McCoy, Los Angeles, favors the placing of cuspidors on street corners and in office buildings, with sewer connections and constantly flushed with running water. This, he believes, would do away with a very potent source of tuberculosis infection.

Los Angeles County Hospital.—An additional tax levy has been ordered which will provide $150,000 for a new county hospital for Los Angeles. The institution is to consist of fifteen two-story wards with accommodations for nurses and attendants, fire-proof and equipped with all modern conveniences.

COLORADO.

Dr. John W. O'Connor, chief surgeon of the Denver and Rio Grande Railway, has been appointed chief surgeon of the Rio Grande Western Railway, vice Dr. Frederick J. Bancroft, resigned.

New Teller County Hospital.—The plans for a new county hospital, to be located at Cripple Creek, have been approved by the State Board of Charities and Corrections, and the building will be speedily erected. It is to cost $15,000.

GEORGIA.

Personal.—Dr. Everett Daniel, Boston, has located in Moultrie.——Dr. W. C. Kellogg, who has been in service at the National Soldiers' Home, Washington, D. C., has opened an office in Augusta, with Dr. Theodore E. Oertel.——Dr. Craig Barrow has returned from his studies in Germany and will practice in Savannah.

Memorial to Dr. Holt.—The Macon Medical Association, at its meeting, September 20, passed the following resolutions: "That this Association recognizes an irreparable loss in the death of Dr. William Flewellen Holt. That his high tone, dignified courtesy and beautiful character commend him to the whole profession as one of its worthiest members, whose example is deserving of closest imitation."

Whisky Prescriptions.—Four Forsyth physicians who are also proprietors of drug stores and have furnished whisky on prescription to patients, have been indicted by the grand jury for failing to register as dealers and to pay the state tax of $200. The first called was found guilty and fined $400. When the cases against the others were called, they, believing that the indictments against them were illegal, refused to appear in court and their bonds were forfeited. The physicians say that when they pay their State professional tax they have a right to prescribe any medicine they may deem necessary.

ILLINOIS.

St. Mary's Hospital, Quincy.—The new addition to St. Mary's Hospital, Quincy, was formally dedicated, September 17.

Smallpox at Quincy.—A new case of smallpox was discovered at Quincy, September 23, and the patient taken to the City Hospital.

The Board Enjoined.—Dr. James A. Marshall, Pontiac, who claims that the Board of Managers of the State Reformatory are endeavoring to remove him for political reasons, has secured an injunction restraining the board from removing him.

Consumptives' Hospital.—The cornerstone of St. Anne's Hospital, Austin, a home for consumptives, which is being erected by the Sisters of St. Elizabeth Hospital, will be laid October 20. The building will cost $150,000 and will occupy grounds of ten acres.

Personal.—Dr. Henry T. Schildroth, Belleville, has been appointed medical examiner to the Civil Service Commission and has gone to Washington, D. C.——Dr. Thomas J. O'Malley has moved from Joliet to Chicago.——Dr. Edgar Thompson, U. S. Navy, has been visiting friends in Lebanon. He has been on duty in the Orient for two years.——Dr. Louis Ostrom has returned to Rock Island from Kansas.——Dr. William Wood, Cairo, is seriously ill at his home, Woodside.——Dr. Paul Healy has purchased the practice and property of Dr. William K. Farley, Waterman.

Chicago.

The College of Physicians and Surgeons held its opening exercises, October 1, Dr. Sanger Brown delivering the address.

Bequest to Presbyterian Hospital.—By the will of the late Henry C. Durand, Lake Forest, $10,000 is bequeathed to the Presbyterian Hospital.

Personal.—Dr. Alexander Hugh Ferguson has returned from Europe.——Dr. Ludvig Hektoen returned, last week, from his summer of study in Europe.

The Woman's Medical School of Northwestern University held its thirty-second annual opening exercises, October 1. The annual address was given by Dr. Martha Foote Crowe.

Rush Medical College graduated a class of 16, September 30. The address was delivered by Dr. Ferdinand C. Hotz. On October 1 the fall term opened with a large increase in the number of students.

Scarlet fever is said to have taken a strong hold in Austin; 17 cases have been reported. In Rogers Park the epidemic is thought to be under control and the school which had been closed was opened this week.

Chicago Medical Society.—The first meeting of this Society after the summer vacation was held in the new meeting-place, Schiller Hall, October 2, President Fenger in the chair. Dr. N. S. Davis, Sr., delivered an address on "The Origin and Progress of the Chicago Medical Society," and Dr. W. A. Evans presented a paper on "Fat Necrosis."

Illinois Medical College held its annual commencement exercises, September 26, graduating a class of fourteen. Dr. Henry Sewall, of Denver, delivered the doctorate address on "The Physician's Ideal." The new college buildings at Halsted Street and Washington Boulevard will be ready for occupancy January 1, 1902. In the evening a banquet was given at the Auditorium Hotel, at which Dr. Seth S. Bishop was toastmaster.

Northwestern University Medical School.—At the opening exercises of this school, October 1, a handsome portrait of Dr. N. S. Davis, Sr., was unveiled. The presentation speech was made by Dr. Winfield S. Hall, who spoke of the connection of Dr. Davis with the school for many years, and the portrait was accepted on behalf of the faculty by Dr. John E. Owens. Dr. N. S. Davis, Jr., who now occupies the position as dean of the school, formerly held by his father, presided and introduced James H. Eckels, who delivered the address of the evening. Rev. Robert D. Sheppard, D.D., spoke on behalf of the university and told of the advantages the occupancy of the Tremont House property would give to the medical students. Dr. Arthur R. Edwards, secretary of the medical faculty, spoke briefly. The enrolment in the medical school is 450, which is 100 more than in former years.

Diminishing Infant Mortality.—A satisfactory disclosure of steadily diminishing infant mortality was made during the week just ended, through a compilation of the records for the summer months of 1899, 1900 and 1901, made by the Department of Health, in response to a request from an eastern sanitarium for infants and children, and the figures are as follows for the months of June, July and August in the respective years: In 1899, total deaths under 1 year of age, 1819; in 1900, total 1551; in 1901, total 1545. These figures give annual death rates per 1000 of population of 4.43, 3.65 and 3.51, respectively; and of total mortality at all ages, 28.4 per cent., 26.2 per cent. and 24.5 per cent., respectively. Thus, in the last three years the mortality of infants has diminished 13 per cent. in proportion to total mortality at all ages and 20 per cent. in proportion to actual population, and there were 274 fewer infant deaths this year out of a population of 1,758,000 than in 1899 out of a population of 1,639,000.

IOWA.

Personal.—Dr. Paul Gardner, West Union, has located in New Hampton.——Dr. Addison J. Beebe has moved from Greeley to Hudson.

Hospital Fair.—The women of the Ottumwa Hospital Association are to conduct a county fair, October 10 and 11, for the benefit of the hospital.

Communicable Diseases.—Diphtheria is reported to be on the increase at Rowley, where schools and churches have been closed. Smallpox has reappeared in Des Moines, and three light cases of the disease are reported from Red Oak.

KANSAS.

Dr. Thomas Blakeslee, Neodesha, has been removed from his position as deputy internal revenue collector for Southeastern Kansas.

Hospital for Negroes.—The management of Douglas Hospital and Training School, Kansas City, has arranged for the purchase of a site for a hospital and training school in that city for the negro people of Kansas City, Kas., and Kansas City, Mo. An effort is being made to raise a fund for the work and $1000 is now on hand to make the first payment.

To Test Medical Law.—A requisition has been issued by the Governor for Horace L. Wilson, who is now supposed to be in Oklahoma. Wilson is a physician who formerly practiced in Ellis. It is charged that since September 1, when the law went into effect, he has violated its provisions by practicing without a certificate from the State Board of Medical Registration and Examination. It is also claimed that he is not a graduate of a regular medical college or a practicing physician of seven years' standing in the state. By this trial the constitutionality of the medical law will doubtless be brought into question.

Board Serves Free.—From August on the members of the State Board of Medical Registration and Examination serve without pay. The appropriation of $1200 passed by the last Legislature to pay salaries and expenses for the two years ending June 30, 1903, has been exhausted. After the first of September the board will hold meetings but once in three months and the members will pay their own expenses. The expenditures of the board were greater than expected on account of the great amount of work resulting from the issuance to physicians of certificates to practice in the state, as required by the new medical law.

MARYLAND.

Scarlet fever and diphtheria are prevailing in Montgomery County and several of the public schools have been closed in consequence.

Personal.—Dr. C. P. Gowman has moved from Odentown to Crumption.——Dr. Frank Dorsey, of Green Spring Valley, is in Boise City, Idaho.

Smallpox and Typhoid.—Maryland Health Officer Noble reports 16 cases of smallpox near Federalsburg, Caroline County, near the Deleware line and an epidemic of typhoid fever at Burrsville in the same county.

Baltimore.

The University of Maryland opened its year in the medical department without formal exercises.

Baltimore University School of Medicine opened September 30 with an introductory lecture by Dr. B. S. Hayden.

The Woman's Medical College opened its session October 1, with addresses on "The Medicine and Doctors of Juvenal," by Dr. Cordell, and on "The International Congress of Tuberculosis," by Dr. R. H. Thomas.

Maryland Medical College.—At the opening of Maryland Medical College Dr. William H. Pearce delivered the introductory address on "The Evolution of the Medical Profession." Baltimore Medical College began its year with an introductory address by Dr. S. K. Merrick, on September 26.

Care of the Insane.—The Board of Estimates approved the request of the Supervisors of City Charities for an additional $15,000 appropriation for the care of the insane in order to relieve the overcrowded condition of Bayview Hospital, making the total appropriation for the insane $119,400.

Infectious Disease Hospital.—A site has been selected for the infectious disease hospital on the Reisterstown Road, not far from Druid Hill Park. A tract of 10 acres has been bought for $20,000; $25,000 was appropriated some time ago for the purpose. The old quarantine grounds on the Patapsco opposite Fort McHenry, embracing 100 acres, will be sold. It is expected that $50,000 to $75,000 can be gotten for it which will help to put up a new building.

Personal.—Dr. Samuel C. Chew returned from Europe September 25.——Dr. James E. Willing has returned from a visit to the New England coast.——Dr. Marie E. Thalwitzer has returned from Europe.——Dr. John N. Mackenzie has returned from Narragansett Pier.——Dr. William Lee Howard has returned from his yachting excursion to the Azores.——Drs. Harvey Cushing and Mactier Warfield have returned from Europe.——Dr. W. G. MacCallum of Johns Hopkins Hospital has returned from his vacation.——Dr. Robert W. Johnson has returned from Europe.——Dr. F. M. Owens has been appointed resident physician at the City Hospital.——Dr. Melvin Rosenthal, who has recently returned from Europe, has been appointed associate professor of diseases of the skin at the College of Physicians and Surgeons.——Dr. Ira Remsen returned on September 23 to Baltimore after spending the summer in Maine and Massachusetts, but left again two days later to deliver the address at the dedication of the new laboratory of chemistry at Oberlin College, Ohio. While away Dr. Remsen finished another of his series of text-books on chemistry which is now ready for publication.

MICHIGAN.

Ann Arbor Medical Students, registered up to September 27, numbered 432, a decrease of 37 as compared with 1900. This falling-off is probably due to the changes in the requirements for admission.

Lying-in Hospitals.—The Detroit Board of Health has appointed Drs. Kennedy, Guy L. Kiefer and John L. Irwin a committee to investigate applications for licenses under the new law regulating lying-in hospitals.

No Spitting in Grand Rapids.—The Grand Rapids Board of Health has authorized signs to be made reading "No Spitting on the Sidewalks. By Order of the Board of Health," which are to be placed in prominent positions throughout the city.

Personal.—Dr. Murdock Kerr, health officer of Laurium, has resigned.——Dr. K. G. Brandes, Owosso, has moved to Quincy, Ill., where he has a hospital appointment.——Dr. James W. McMeekin, Saginaw, is recovering from a severe illness caused by septic infection.

August Mortality.—There were only 2672 deaths returned to the Secretary of State for the month of August, corresponding to an annual death rate of 13.1 per 1000. This is an unusually low mortality for August, the number of deaths returned being nearly 300 less than for August, 1900.

MINNESOTA.

St. Luke's Hospital.—The new St. Luke's Hospital, Duluth, is so well under way that it is now expected that it will be completed by Feb. 1, 1902.

Smallpox is spreading among the Indians in the state. It has appeared in virulent form on the Fond du Lac reservation, but has been apparently checked on the Mille Lacs reservation.

Diphtheria in virulent form has broken out at Friber, Otter Tail County, where six cases are reported. The disease is unusually prevalent in Minneapolis and the health commissioner is using his utmost efforts to enforce quarantine.

Personal.—Dr. Elbert E. Persons, U. S. Army, has been ordered to Fort Snelling to relieve Contract Surgeon Herbert J. Harris, who has been transferred to the Department of Cuba.——Dr. Louis B. Rennick, Glenwood, has moved to Lidgerwood, N. Dak.——Dr. James W. Robertson, Litchfield, has been appointed pension examining surgeon.

The Medical Department of the University of Minnesota held its opening exercises, September 23, in the old medical building, Minneapolis. Addresses were delivered by President Northrop, Dr. Parks Ritchie, Dr. Jacob E. Schadle and the Governor of the state. Dr. Schadle in his address reviewed the history of medicine from 500 B. C. to the present time.

NEW JERSEY.

Overbrook Asylum.—The new wing at Overbrook Asylum is now ready and 80 female patients have been transferred to their new quarters.

Did Not Report Disease.—An Orange and a Jersey City physician have been arraigned for failing to report cases of contagious disease, as required by law.

Personal.—Dr. Charles Waters has opened an office in Trenton.——Dr. Henry R. Baldwin, New Brunswick, was stricken with paralysis at Trenton, September 26.

Authority of Board of Medical Examiners.—A Newark applicant for a license to practice medicine, who was refused examination by the Examining Board on the ground that he had been convicted of malpractice, proposes to test the legality of the medical act. His attorney claimed that as his client had pursued a medical course in a reputable medical institution and had a certificate to that effect, had deposited the required fee and complied with all other legal preliminary requirements, the Board had exceeded its authority in refusing to allow him to take the Examination. He holds that the Board's province is to pass on the medical skill of applicants and not on their moral fitness. The Board, however, did not change its ruling.

NEW YORK.

Mystery Solved.—The mysterious disappearance of Dr. Charles W. Hoyt, Corning, has been cleared up by the finding of his body in Lake Erie, near Geneva, Ohio.

Personal.—Dr. Harold L. Baldwin, Syracuse, has entered into partnership with Dr. Henry C. Baum.——Upon the expiration of his term of office as Assemblyman, Dr. Nelson H. Henry, New York City, is to become Adjutant-General of this state.

School Children Examined.—The bureau of health of Syracuse has decided that the pupils of the public schools must be examined as to the condition of their health, twice a month. The principal object is to guard against contagious disease, but the physicians will also try to detect and remedy other physical defects. Defects in eyesight especially will be remedied as far as possible.

Sues State Hospital.—Dr. Marie L. Benoit, New York City, has brought suit against the board of managers of the New York State Custodial Asylum for Feeble-Minded Women.

Newark, and seeks to obtain reinstatement on the civil service list and salary, with value of maintenance as provided by law, for the months of July, August and September of this year. The plaintiff accuses the managers and the superintendent of breaking their contract with her, the terms of which, she claims, guaranteed her the position of resident physician at the institution until October 1. She claims her removal was ordered because she criticised the quality of the food supplied to the patients.

Albany Medical College opened for the session of 1901-1902 on September 24. Dr. Howard Van Rensselaer delivered the opening address. The following changes in faculty have been made: Dr. Willis G. Tucker, successor to the late Dr. Maurice Perkins, as professor of chemical philosophy and organic chemistry. Dr. Howard Van Rensselaer will be professor of materia medica, vice Dr. John V. Hennessy, resigned. The following appointments have been made as clinical professors: Dr. Leo Haendel Neuman, theory and practice of medicine and gastro-enteric diseases; Dr. Jesse Montgomery Mosher, insanity, neurology and electro-therapeutics; lecturers: Dr. William Olin Stillman, history of medicine; Dr. Harry Judson Lipes, obstetrics; Dr. Charles Harper Richardson, minor surgery; Dr. Arthur Wells Elting, surgical pathology; Dr. George Emory Lochner, gynecology, and Dr. Arthur Turner Laird, clinical microscopy.

Buffalo.

Professor Czerny, Heidelberg, Germany, has been a guest of Dr. Roswell Park.

Dr. C. A. Haman, Cleveland, read a paper on "Spasmodic Torticollis and Its Surgical Treatment" before the Surgical Section of the Buffalo Academy of Medicine, Tuesday, October 1, 1901.

The Experts Who Examined Czolgosz as to his sanity will be allowed fees by Erie County, at the rate of, approximately, $100 per examination. It will cost Erie County in the neighborhood of $2000 for their services.

The Medical Department of the University of Buffalo opened its fifty-sixth annual session, Sept. 30, 1901. Dr. F. C. Busch, professor of physiology, delivered the address of welcome, a review of the advances in medicine and surgery.

Emergency Hospital.—The throng of sightseers which daily has besieged the emergency hospital at the Pan-American Exposition since the wounded President was treated there, has become so great that the hospital staff found it almost impossible to perform the regular duties. A sign has been displayed that non-professional visitors are requested not to take up the time or attention of the hospital staff. Up to the time of the shooting the hospital was looked upon as a sort of exhibit and was open to the public at all hours of the day.

OHIO.

Dr. Lansing's Estate.—The estate of the late Dr. R. H. Lansing, Chillicothe, is valued at from $35,000 to $40,000.

Diphtheria is prevalent in Coshocton. Two Zanesville physicians have been arrested on the charge of failure to report cases of the disease.

Toledo Medical College held its twenty-first annual opening exercises, September 26. Addresses were made by Rev. Dr. Belsey, Dr. John S. Pyle and other members of the faculty.

The College of Physicians and Surgeons, Cleveland, for its forty-first term, opened September 18, without formal exercises. Dr. Charles B. Parker made a short address of welcome to the students.

Osteopath Arrested.—On complaint of Health Officer Beardsley, of Findlay, an osteopath of that place was arrested, September 24, charged with practicing medicine and with prescribing drugs for the cure of physical ailments, without complying with the state laws governing physicians.

Personal.—Dr. John F. Hesse had a second attack of paralysis at his office in Cincinnati, September 16, and is in a critical condition.——Dr. John E. Brown, Columbus, has returned from a three months' trip to Europe.——Dr. Edward Vail, Newark, the oldest practitioner in Licking County, was stricken with paralysis, September 21.

PENNSYLVANIA.

Measles is epidemic in South Williamsport.

A correspondence school of personal magnetism, magnetic healing and hypnotism is the latest Philadelphia novelty.

Woman's Medical College, Philadelphia, opened its fifty-second annual session, September 25. The address was delivered by Dr. Caroline M. Burnell.

A reception was tendered by the trustees and the faculty of the Medico-Chirurgical College, Philadelphia, to the members of the State Medical Society, guests and visiting ladies, at the college building, September 26, from 5 to 7 p. m.

Protest Against Isolation Hospital.—As vigorous protests were made to the mayor of Philadelphia against the establishment of an emergency hospital for contagious diseases in the twenty-eighth ward, he has directed that all work be stopped and to abandon the proposed location. He has ordered temporary pavilions to be constructed within the hospital enclosure.

Personal.—Dr. A. E. Stoits, Philadelphia, has located in Williamsburg.——Dr. J. A. Trexler, Macungie, has purchased the practice of Dr. Wagner, of Pikesville, and will locate in that place.——Dr. Edwin R. Rasely, Vanderbilt, has moved to Uniontown. He is to be resident physician for the Rainey Coke Company.——Dr. Judson Daland has returned to Philadelphia after his summer vacation, which was spent in European travel.——Drs. Thomas C. Buchanan, Honeybrook, and W. E. Fisher, have opened offices in Reading.

TEXAS.

Smallpox is reported to be epidemic in Ellis County.

Southern Pacific Hospital.—A hospital building is to be erected at El Paso by the Southern Pacific Railroad Company, which will accommodate fifty patients.

Fort Worth University Medical Department opened October 1, with appropriate exercises. The only notable change in the faculty is in the chair of anatomy, which is now held by Dr. Gardiner, who succeeds Dr. William R. Thompson, resigned.

Mosquito Warfare.—Galveston has arranged for a large supply of crude oil from the Beaumont wells, which will be sprinkled on all stagnant pools and gutters in the city and will be given to owners of open cisterns for use in destroying mosquitoes.

Personal.—Dr. John D. McMillan has sold his residence in Biardstown to Dr. Jefferson D. Skidmore, and will move to Paris.——Dr. E. C. Barham, Duffon, has moved to Hico.——Dr. T. J. Hubbert, Hico, has moved to Fort Worth.——Dr. E. D. Capps, Fort Worth, who has been in Europe the greater part of the summer, has returned to New York and will soon return to Texas.

WISCONSIN.

Milwaukee Medical College opened for its eighth annual session, September 17. Dr. John J. McGovern is the new professor of anatomy. More than 500 students have matriculated.

Smallpox has been reported at North Fond du Lac, imported from Colby, and is among the Winnebago Indians, at Brockway, where 100 cases are said to exist. It has also been reported at Sheboygan, said to have been brought from Sturgeon Bay, and at Newton.

To Enforce Smallpox Law.—Dr. G. O. Switzer, Stanley, has been appointed special medical inspector and agent of the State Board of Health for Chippewa and Taylor counties. Dr. Frank B. Hicks, city health officer of Washburn, has been named as the special representative of the State Board of Health to look after the work of suppressing smallpox in Bayfield county.

Personal.—Dr. L. W. Zochert, Hingham, has settled in Fond du Lac.——Dr. J. Johnson Heeren, Marinette, is located on a fruit ranch near Mimbres, N. M., and is regaining his health and strength.——Dr. Cora A. Turner-Saxe, Delavan, has sold her practice to Dr. Rebecca Rhodes, and will go to Everett, Wash., early in October.——Dr. Albert G. Jenner, Milwaukee, sailed September 19 for Europe on the *Spartan Prince*.——Dr. George H. McCallister, Elkhorn, has sold his practice to Dr. T. H. McCarthy, Stoughton.

GENERAL.

Surgeon General George M. Sternberg, U. S. A., arrived at San Francisco, October 1, from Manila.

Gift to Manila Hospital.—Mr. Whitelaw Reid, New York, has made a second gift of $5000 to the Woman's Hospital, Manila.

Plague at Rio Janeiro.—President Roca has signed a decree declaring that the port of Rio Janeiro is infected with the plague.

Examination for Physicians for Indian Service.—An examination will be held on October 22, for the position of physician in the Indian service, at White Earth Agency, Minnesota, at a salary of $900 a year.

American Hospital in Paris.—The project of erecting an American hospital in a suburb of Paris, which was about to be abandoned, has been revived by a donation from the Duchess of Marlborough of $10,000, and by the promise of a similar amount from her father, Mr. W. K. Vanderbilt.

Records of International Congress of Medicine.—The General Secretary of the 13th International Congress announces that the general volume and the seventeen records of the sections are ready for delivery. Any member who has not received the volumes and is entitled to them is requested to address the Editors of the Congress, Mrt. Masson et Cie., 120 Boulevard Saint Germain, Paris, not later than December 15, 1901.

Egypt's International Medical Congress.—An International Congress of Medicine will be held under the patronage of the Khedive of Egypt, at Cairo, in December, 1902. It will be the first great gathering of scientific men ever held in an oriental country. The subjects to be considered more particularly will be the diseases that come from the East, cholera and the bubonic plague, as well as forms of dysentery and ophthalmia prevalent in eastern lands. Among the medical men who are promoting the congress are Abbate Pasha, Tomanos Pasha, physician to the khedive; Ibrahim Pasha Hassan, dean of the Cairo Medical School; Mol Eloui Bey, the ophthalmologist, and the chief Egyptian physicians, native and foreign. Dr. Varonoff is secretary general of the committee in charge of arrangements.

An examination for colored doctors will be held October 29 and 30 by the United States Civil Service Commission, at Washington, D. C., for the position of assistant surgeon of the Freedman's Hospital. The examination is open to all citizens of the United States, and full information can be obtained by applying to the Commission Board. No one under 20 years of age is eligible. The subjects upon which the questions will be asked are: Letter writing, anatomy and physiology, surgery and surgical pathology, chemistry, materia medica, therapeutics, bacteriology and hygiene, theory and practice of medicine and general pathology, obstetrics and gynecology. The Freedman's Hospital is an institution established at Washington, D. C., for the free care and treatment of colored patients. It is understood that it is the custom of the department to appoint only colored people to positions. From the number of those who successfully pass the coming examinations, appointments will be made. The position carries a salary of $1000 to $1500 a year.

CANADA.

Asylum Staff Changes.—Dr. Harvey Clare, assistant physician at the Asylum for Idiots, Orillia, has been promoted to the position of assistant physician at the Asylum for the Insane, Brockville, to succeed Dr. Wilson, who has been transferred to the London Asylum.

Dowieite Convicted.—On the 26th inst. Mr. Justice Walker, of the British Columbia courts, found a member of the "christian catholic church in zion" guilty of manslaughter, on the charge of failing to provide proper medical attention for his two children who died from diphtheria.

Death of a Centenarian.—In the village of Troy, which is situated a short distance from the city of Hamilton, Ontario, there died the other day a man who had reached a ripe old age, Adam Misener, aged 103 years and seven months. There is no doubt about the authenticity of this man's great age. He was well known to the writer.

Annual Report: Provincial Board of Health, Ontario.—The nineteenth annual report of the Department of Public Health in Ontario has just been issued, and it deals with the year 1900. In a population set down at 2,302,705, there occurred 25,382 deaths, or 11.9 per 1000, the average population reporting being 93 per cent. The deaths occurring from consumption are set down at 2360.

Trinity Medical College Opening.—On the afternoon of the 25th inst. the opening lecture of the session of 1901-1902 was delivered by Professor Charles Sheard. Dr. Brennan, an old graduate, who was President Kruger's physician when the South African war broke out, but who immediately left him and joined the British forces, was present, and was welcomed by a number of old friends.

Quebec Medical Council.—At a meeting of the Board of Governors of the College of Physicians and Surgeons of Quebec, held on the afternoon of September 25, the following officers were elected: President, Dr. Lachapelle, Montreal; vice-presidents, Dr. Vallee, Quebec, and Dr. Craik, Montreal; registrar, Dr. Marsolais; treasurer, Dr. Jobin, Quebec; secretaries, Dr. McDonald, Montreal and Dr. Paquin, Quebec.

Something About the Birth Rate in Canada.—After all, it would appear that the largest families are not in the province of Quebec, but in Prince Edward Island, where five persons and four-fifths of a person constitute a family, according to the Toronto *Globe*. The Quebec family is said to consist of five and one-half; New Brunswick has the same record, while Nova Scotia has one-tenth of a person less. In Manitoba, British Columbia and the Territories the family is less than five.

The Outbreak of Anthrax in the Northwest.—Much alarm is experienced among cattlemen in Toronto and Montreal lest anthrax, which has been so widely prevalent in the Canadian Northwest, be introduced into Ontario, generally, one or two districts now being already infected. Over 4000 sheep belonging to one company in the Northwest are dead and considerable loss among cattle and horses is also reported. The disease was brought into that part of the Dominion by Australian sheep-shearers. It is understood that owing to the general quarantine immediately set on foot the outbreak is being held in check.

Smallpox.—Smallpox has reappeared in the Island of Manitoulin, but in a very mild form. The Provincial Health Department has ordered that all cases and suspects be quarantined and that vaccination be generally enforced. The outbreak at Ottawa begins to assume a serious aspect. It is understood that Dr. Robillard, who has been health officer of the city for over twenty years, has resigned on account of being hampered and criticised in his work. An employe of the census bureau has contracted the disease and Dr. Montizambert, the Director-General, has had to vaccinate the entire staff of that department. Toronto has been declared free of the disease by the medical health officer.

FOREIGN.

Hospital at Port Arthur.—The Russian government is erecting a sanitarium at Port Arthur at an expense of 200,000 roubles.

Dresden school children show, as the results of the medical inspection of all school children, that 50 per cent. deviate from the normal standard.

Women Excluded.—The professors of anatomy, chemistry and physics at the University of Königsberg have excluded women students from their lectures.

The German Balneologic Association has published an appeal for subscriptions to erect a memorial in honor of H. Brehmer, the father of the tuberculosis sanatorium.

International Exposition of Photography.—Dr. A. E. Stein, Berlin, assistant at Bergmann's clinic, obtained the prize for medico-scientific photography at the recent exposition in Weimar.

Prize Founded in Honor of Tokarski.—The patients and admirers of the recently deceased Moscow professor, A. Tokarski, are collecting subscriptions to establish a quadrennial prize to bear his name, to be awarded for the best work on the application of hypnotism to the treatment of nervous diseases.

Country Homes for the Convalescents of the Paris Hospitals.—The Paris authorities are seriously considering the proposition of sending convalescents dismissed from the hospitals to board in families in the country. The expense is less than to establish sanitariums, while the physical and moral advantages are considered superior.

Jockey Hospitals.—It is not generally known that Newmarket, England, and Chantilly, France, have each a hospital for jockeys only, where those injured in the races or suffering from any except contagious diseases are admitted and cared for in a princely manner. The *Gaz. Méd. de Paris* states that the Chantilly hospital has two permanent inmates, pensioned and retired on account of age.

Free Post-Graduate Medical Courses in Berlin.—The central committee organized to "promote the perfecting of the art of medicine in Prussia," by holding post-graduate courses, reports that 1140 physicians have made application in Berlin this year, against 797 in 1900. There are now nineteen courses, and a series of conferences on military surgery and medicine, and also on industrial accidents from the medicolegal point of view.

Hirschberg's Library.—The famous ophthalmologist of Berlin, J. Hirschberg, has compiled a catalogue of the works in his library on his specialty, with a brief descriptive outline of the contents. It forms a volume of 434 pages, and as the collection is destined for the library of the Berlin Medical Society, ophthalmologists are rejoicing. The *Deutsche Med. Wochenschrift* remarks that the Hirschberg ophthalmologic collection is the most extensive and complete in the world.

Virchow's Birthday Festivities.—The official celebration commences on the day before the birthday, October 12, with the inspection of the newly-installed collections of the Pathological Museum, to which Virchow himself issues the invitation. At six p. m. a banquet is tendered to Virchow and his family, the delegates from abroad and his most intimate friends. It will be held in the Prussian Abgeordnetenhaus or House of Deputies, and afterwards the party will adjourn to the assembly hall, where the delegates and others will present their greetings and contributions to the famous Virchow Fund, with a souvenir pamphlet containing the names of the contributors. The city of Berlin has voted to contribute 100,000 marks—about $25,000—to the fund. The medical societies of Moscow are to hold a joint session on that day in honor of Virchow, and, besides sending a deputation to Berlin, have commenced collecting funds to establish a Virchow scholarship at the university. The Paris Society of Anthropology sends a gold medal in his honor.

French War on Consumption.—Since the congress in London, all the individual leagues founded to combat tuberculosis have consolidated into a single gigantic "union for struggle against consumption." Delegates representing all the mutual aid and mutual insurance societies met in the hall of the Sorbonne and agreed to contribute a fund of $10,000 yearly for the support of 100 beds in the hospitals of each large city in France, besides supporting 300 free consulting-rooms in public sanatoriums throughout the country for the coming year. Moreover, the members of the new union purpose publishing a periodical devoted solely to fighting the disease, which annually destroys so many lives in France. This periodical will be edited principally by Dr. Calmitte, head of the Pasteur Institute at Lille. The organizers of the present movement, which is the largest yet established, hope that a similar move will be made in the United States and Great Britain. A beginning in this line has already been made in Germany.

LONDON LETTER.

Tuberculosis in Animals.

The Local Government Board has issued to the Borough Councils a letter dealing with the tuberculosis question in which it is pointed out that the views of Professor Koch have not received the assent of scientific men and that pending the Report of the Royal Commission there should be no relaxation in the measures dealing with milk from tuberculous cows and with tuberculous meat. As the action of the local authorities is not uniform the Board calls attention to the report of the Royal Commission on Tuberculosis held in 1898 as to the degree of tuberculous disease which should cause a carcass, or a part thereof, to be seized. This commission was of opinion that the entire carcass and all the organs of cattle might be seized, 1, when there is miliary tuberculosis of both lungs; 2, when tubercular lesions are present on the pleura and peritoneum; 3, when tubercular lesions are present in the muscular system or in the lymphatic glands embedded in or between the muscles; and that the carcass if otherwise healthy should not be condemned, but every part containing lesions destroyed when the lesions are confined to the lungs and thoracic lymphatic glands, when the lesions are confined to the liver, when the lesions are confined to the pharyngeal lymphatic glands, and when the lesions are confined to any combination of the foregoing, but are collectively small in extent. In pigs, in view of the greater tendency of tuberculosis to generalization, the Commission considered that tubercular deposits in any degree should involve seizure of the whole carcass and of the organs. In respect of foreign dead meat, seizure was recommended in every case in which the pleura had been "stripped." The Local Government Board now strongly urge the Borough Councils to enforce these regulations.

Major Ross' Anti-Malarial Campaign.

A letter has been received by the Chairman of the Liverpool School of Tropical Medicine from Major Ronald Ross, giving information of the results of his visit to the Gold Coast and of the work of the fifth expedition of the school. He first refers to the admirable measures of Sir William Macgregor at Lagos, which have been already described in The Journal. At Accra, arrangements have been made to improve the condition of the Europeans by buying up several poor locations planted in their midst. An admirable plan has been formed for laying out the town of Sekondi in accordance with scientific requirements by buying out the poor locations on the foreshore, extending the European quarters along the bluff to the east, and placing the native town apart—behind the railway. Major Ross informed the governor that he did not think that the housing question would in itself put a stop to the fever and that the measures adopted at Freetown and Lagos should be extended as soon as possible, and that considering the importance of the matter the Liverpool School of Tropical Medicine would consider the advisability of sending a delegate to direct operations. At Sierra Leone he found a gang of men employed in clearing the larvæ of mosquitoes out of the houses. In 34 days they had cleared 2473 houses and removed 358 cartloads of empty tins, broken bottles and such like in Freetown. It is calculated that one in three empty tins is a breeding-place for mosquitoes. A serious blow has, therefore, been struck at the prevalence of the culex mosquito in the town. Major Ross calculates that an annual expenditure of only £100 would keep the town free from mosquitoes. Already their numbers are greatly reduced. These culex mosquitoes, besides causing annoyance, carry the germs of yellow fever, elephantiasis, and other diseases. Operations against the anopheles mosquito, which breeds in puddles, are also being pushed. Hollows in the ground are everywhere being drained or filled with earth. Others are being filled with the empty bottles and tins found in the houses. Many of the worst streets, which were practically marshes, have been reclaimed. The unhealthfulness of the Gold Coast, Major Ross believes, has been much exaggerated. True, there is a considerable amount of malaria among Europeans, but there is little or no typhoid. Everywhere men are met who have lived on the coast for years in good health. It is the young, reckless, improvident and sometimes intemperate newcomer who generally falls a victim to disease. If a man contracts malarial fever now in 9 cases out of 10 it is his own fault. The scrupulous use of a mosquito net is necessary.

Lunacy in 1900.

The report of the Commissioners in Lunacy for 1900 has just been issued. The total number of lunatics of whom they had notice in 1900 was 107,944—an increase of 1333 for the year as against increases of 1525 in 1899 and 3114 in 1898. As the average annual increase for the last five years has been 2300, the increase for 1900 must be considered small.

The Gelatin Treatment of Aortic Aneurism: Fatal Tetanus Produced.

At Guy's Hospital a very unfortunate result has followed in the case of two patients undergoing this treatment. Three patients—a carter, aged 37, an engineer's laborer, aged 33, and a third one—underwent the gelatin treatment about the same time. The latter was discharged, according to the opinion expressed at the inquest, thoroughly cured. But the two former have died from tetanus. What the weak links in the chain of antiseptic precautions were is not known. It is difficult to believe that the spores could have been in the original gelatin and resisted the prolonged sterilizing processes to which it was subjected.

The Outbreak of Smallpox in London.

The outbreak of smallpox, which has been previously described in The Journal, appears to be on the decline. In eight weeks, ending Sept. 7, 135 cases were admitted to the hospital, and of these, 113 were admitted during the last three weeks of that period. For the week ending August 24 there were 30 cases; August 31, 52 cases, and September 7, 31. The cases have not come from one quarter of London, but from all over the metropolis. A source of anxiety is the large number of unvaccinated children in London, the result of the recent vaccination act which practically abolishes compulsion. It is estimated that a third of the children who attend elementary schools are unvaccinated. The difficulty of diagnosis which the ordinary physician experiences has been previously mentioned in The Journal. Vaccination acts in two ways in producing this difficulty—by rendering cases so rare that most doctors have never seen the disease and by modifying the eruption. Suspected cases are first removed to shelters where they remain under observation until the diagnosis is definite; in case the patients are suffering from smallpox they are then removed to hospital ships in the Thames, which are specially reserved for the disease.

Correspondence.

Aim of Medical Education, and Its Relation to Research Work by Medical Students.

CHICAGO, Sept. 23, 1901.

To the Editor:—The editorial in your issue of Sept. 21st, commenting upon my paper on "The Aim of Medical Education, and Its Relation to Research Work by Medical Students," which appeared in the same issue, shows such a lack of understanding of the points of the paper that I beg the privilege of reply.

The writer of the editorial has distinctly misunderstood my use of the expression: "Original research has for its object the determining of new truths of a more or less general character." I do not blame him for this, as the language is imperfect, and I felt it at the time of writing. The language would have been better had I omitted the limiting phrase, "of a more or less general character." What I had in mind, however, which gave rise to the phrase was this: Every truth in one of the basic sciences which bears upon "clinicism," has in the latter numerous applications; it is, therefore, to the latter "more or less general." The point, however, is not important, and to discuss it further would lead to a mere tangle of words, something I wish to avoid. To further clear the way for true discussion, I grant at once that all knowledge is relative and that speculations as to the "absolute" have no place here. Furthermore, I can not see how anything I said could have led to his very true, but wholly irrelevant statement: "Only occasionally does that master mind appear which is capable of new generalizations, justifiably far-reaching." He asks: "Again, is it fair to consider that work unworthy of the name of research which, though it fail to say the last word upon the problem upon which it is engaged, gathers all the data at the time available, reflects upon them and draws legitimate inferences from them, even when the result is only an approximation to the whole truth?" He thinks not; so do I. But the whole question is irrelevant. The question has probably arisen from the following in my paper: "As Huxley says: 'There is one guiding rule by which a man may always find this path [to truth] and keep himself from straying when he has found it. This golden rule is—give unqualified assent to no proposition but those the truth of which is so clear and distinct that they can not be doubted.' Any so-called research less critical is unworthy of the name." If by "legitimate inferences" he means inferences which meet the requirements of Huxley's rule, then we are in accord. My objection is not to the research or its incompleteness, but to tentative conclusions. The problem actually solved is the one formulated by just conclusions. The question which the editor asks appears, however, unfair in that it implies a criticism (erroneous as has been shown) of a portion of an argument away from its context, and entirely overlooks the point of the argument. I am sure that upon sober second thought the editor will lose the fears which he expresses as to the ultimate outcome of the "medical mode of thought." The matter is too extensive for proper exposition in a letter, but in a paper to be presented later, I shall show that it requires no less accuracy of observation nor less of logical reflection than characterizes all scientific methodology, but on the contrary rather more than most scientific procedures, and that its great characteristic is that it is on the whole much more difficult than most work in the basic sciences, because of the inherent peculiarities of the subject matter, with which it deals.

Upon the question of the relation of medical students to research work, he agrees that the majority of medical students are unfitted, especially during their undergraduate years, for original research; and gives reasons for it with which I fully concur. The reason which I give for this same position he does not agree with and in stating it does not state it exactly as given. He further says: "But has he any evidence which would indicate that such an assumption is true? Surely, every-day experience points to the opposite view, and certainly the statements made in his paper can scarcely be regarded as convincing." The alleged assumption relates to the differences which exist in the process of diagnosis and in that of research. I feel quite sure that the assumption will be granted by medical men who are in the habit of making thoughtful and careful diagnoses daily. He also presumably includes in the assumption my statement that research in the basic sciences is capable of being harmful to the young medical man. He offers no evidence to support his own view; the evidence by which I support mine will be presented in my subsequent paper.

Very respectfully, W. S. CHRISTOPHER, M.D.

The Function of the Appendix.

NEW YORK, Sept. 20, 1901.

To the Editor:—On page 852 of THE JOURNAL for Sept. 28, 1901, I find a report of a paper read by Dr. E. P. Hershey, Denver, dealing with the question of the function of the appendix. Dr. Hershey apparently believes that the secretions of the appendix are important in their influence on bowel contents, but we know that such secretions are trifling in amount and not different from those of the cecum. Most of the appendices upon which I have operated have had their function already destroyed by bacteria. Further than that, we know that during middle life the appendix is prone to undergo normal involution changes, so that in later life there is little if any secreting surface left. Dr. Hershey says of the cecum: "This cul-de-sac is the most inviting place for the accumulations of feces. The mass remains here and would become hardened were it not for the secretions that keep the mass thin and moist." I would like to have a record of actual observations made upon this point. Those of us who see the cecum a good many times in the course of a month, note the fact that it is about the emptiest part of the bowel, and might well have been named the jejunum. I have seen several hardened cecums, and have operated many times in cases in which some one had made the diagnosis of cecal impaction, that never yet, so far as I remember, has the cecum contained any palpable fecal matter. The "fecal impaction" was regularly peritoneal exudate, and usually abscess. I make these points because there are many physicians who are anxious to be right, but who are too busy to become properly informed on the subject of the appendix. They gladly seize upon such data as those furnished by Dr. Hershey in order to escape, if possible, from the dictum of authorities who advise operation in appendicitis as soon as the diagnosis is made. Consequently, it seems no more than fair in the interests of science and humanity if we ask Dr. Hershey to give us the result of carefully recorded, accurate observation. In the East we have learned to look at Denver as a city containing representatives of all that is best in modern medical knowledge, and it is unfortunate to have a false note sounded from a section of the country that has gained so well-merited a reputation.

ROBERT T. MORRIS.

Why Withhold Tobacco?

TOLEDO, Sept. 25, 1901.

To the Editor:—This question, whether he should be permitted to smoke or not, came up in the treatment of our late President, and possibly has in it a lesson which should be considered on account of the applicability which it may have to the treatment of surgical cases generally. Does the sudden stopping of the habitual use of tobacco make the bodily functions more resistant to the processes of disease, and more efficient in the healing of wounds? Does the nervous system suffer and lose its balance by withholding its accustomed sedative? Are the secretory system, the excretory system, in fact all of the systems of the body, by the sudden taking from them of the load to which they have learned to adapt themselves, made stronger, or are they left stagnated because the stimulus which has been prompting them to their abnormal action has been removed?

To smoke three or four cigars in one day would probably kill a man who was not accustomed to its use, but the system of the habitual user of tobacco has become so gradually saturated that it, like the system of the arsenicophagy is able to stand the strain. In the case of the arsenic eater instant withdrawal of the poison is sudden death.

Just why the desire for the narcotic stops during sickness, and immediately upon the receipt of injury, is unexplainable. May it not be the fact that the abnormal sedation which the tobacco has been producing gives way to unbalance, irregularity in functions, and destructive action, upon the withdrawal of the narcotics? Is it just possible that in sickness and injuries where desire for tobacco has been lost, that some preparation of tobacco should be regularly administered hypodermically?

J. L. Tracy.

Regarding Christian Science.

Chicago, Sept. 12, 1901.

To the Editor:—In The Journal of July 27 was published what was supposed to be "a sample of Christian Science," "a prayer for a dyspeptic, drawn up by Mr. Hazzard, president of the New York School of Primitive and Practical Christian Science." Please permit me to state through your columns that the gentleman mentioned is not a Christian Scientist, his school is not a Christian Science school, the prayer attributed to him is not a Christian Science prayer, and the publication to which it is credited is not a Christian Science publication. Any deductions, therefore, which might be drawn as to the teachings of Christian Science from the "prayer for a dyspeptic" must be erroneous.

Archibald McLellan.

Book Notices.

La Peste Bubonique dans la Republique Argentine et au Paraguay Epidémies de 1899-1900. Rapport Présenté au Départment National D'Hygiène par les Docteurs Luis Agote et A. J. Medina, Inspecteurs délégués du Gouvernement Argentin. Paper. Pp. 298. Buenos Aires: Felix Lajouane. 1901.

This report of the National Department of Hygiene of Argentina is an evidence of the thorough appreciation of sanitary questions in that South American Republic. The authors give the history of the introduction and course of the disease in succession into Asuncion, Rosario and Buenos Aires, discuss the local conditions in each place that favored its development, devote chapters to treatment and prophylaxis and conclude with an appendix giving reports of cases. They endorse serum therapy as giving better results in the cases in which it has been employed than other methods of treatment, and the accidents or inconveniences following its use slight. They do not, however, unreservedly hold with Haffkine that serum immunization renders needless other prophylactic measures. Where the serum treatment was impossible in these cities the treatment was largely symptomatic—balneotherapy, cardiac tonics, anti-spasmodics, intestinal disinfectants, etc. Incision of the buboes was practiced, and bleeding was found occasionally of value. The work is a valuable contribution to the not yet too ample scientific literature of this recently recrudescing pest of former times.

Transactions of the Vermont State Medical Society, 1900. Published by the Society. Cloth. Pp. 195. Free Press Association, Burlington. 1901.

The Secretary calls attention to the fact that while 15 or 20 new members are added each year, the total enrolment remains practically the same on account of those who are dropped for non-payment of dues. The membership is given as 219, although how many are back in their dues three years is not stated. There are about 600 regular physicians in the State, hence only about one-third are active members of their State Society. The report of the committee on reorganization is an excellent one and contains recommendations, which, if adopted, can not but be a benefit to the profession of Vermont. In the report of the delegates to examine the graduates of the medical department of Dartmouth College, we are informed that the temperature of that day was 143 degrees below zero—rather cool certainly. The volume contains twelve papers, besides the reports, obituaries, etc.

The Office Treatment of Rectal Diseases Explained and Simplified. Being an Exposition of the Treatment of all Those Diseases, Both Medical and Surgical, of the Rectum, Anus and Sigmoid Flexure, the Cure of which May Be Accomplished Without Surgical Anesthesia. Illustrated. By Rufus D. Mason, M.D., Omaha, Neb., Professor of Rectal and Pelvic Surgery in the John A. Creighton Medical College. Cloth. Pp. 83. Price, $1.50. Omaha: E. B. Festner. 1901.

The author does not attempt to cover the field of rectal diseases, but only those conditions that are liable to be met by the general practitioner. As such the book is to be commended.

A Hand-Book of Genito-Urinary Surgery and Venereal Diseases. By G. M. Phillips, M.D., Professor of Genito-Urinary Surgery and Venereal Diseases, Barnes Medical College. Illustrated by Half-tone Cuts and Special Drawings by L. Crusius, M.D. Cloth. Pp. 313. Price, $2.00. St. Louis, Mo.; Lewis S. Matthews & Co. 1900.

The subjects are treated clearly and concisely. The half tones and drawings are unusually good and instructive. For the student and practitioner it will be found a convenient reference book.

Miscellany.

San Francisco Plague Report, Fortieth Verified Death.

Lee Mon Chong, male, aged 40 years, a cigarmaker by occupation, died on Aug. 30, 1901.

Autopsy.—Body of a Chinese male, fairly well nourished; rigor mortis not present; body still warm, pupils moderately dilated, scleræ not injected. Glandular enlargement well marked in left inguinal region, slight enlargement in right axilla; no local lesion to account for enlargement. Two small ecchymotic spots over bubo in the groin, lividity not marked, slight on dependent parts. Upon incising the bubo, a bloody hemorrhagic fluid exuded; the glands were seen to be enlarged, injected, and surrounding tissues edematous. Smears from the gland, stained with carbol-thionin, showed numerous bipolar staining bacilli.

Abdominal Incision.—Subcutaneous fat was moderately abundant; subcutaneous vessels injected; left abdominal muscles infiltrated. Intestines were slightly distended, moist and glistening, showing a number of dark areas, probably submucous hemorrhages. Little or no fluid was in the abdominal cavity; appendix normal.

Diaphragm, attachment, right, 5th rib. Left, 4th interspace. Lungs met in median line but collapsed anteriorly. Left slightly adherent at apex.

Pericardium.—Area was about normal in extent, contains about 10 c.c. of clear yellowish fluid.

Heart.—Surface was covered with fat; vessels slightly injected; heart muscle soft and flabby. Ventricles full of fluid blood; valves normal. Numerous plaques on surface of aorta; coronary openings free. Heart muscle was pale and in some places evidence of fatty change.

Lungs.—Left lung pits on pressure and crepitates throughout. Pressure causes serum and air to exude from cut surface. No nodules. Lung appears normal except for edema. In the right lung, middle and upper lobes pit and crepitate throughout except at the site of an old tubercular scar at apex. The upper and anterior part of the lower lobe is somewhat firmer than normal, but crepitates, especially about the border. The pleura still glistens, color purplish, interspaced with dark dition. The treatment advised is a psychic one, mental or suggestive therapeutics being necessary. A number of cases were described.

President's Address.

Dr. Thomas D. Davis delivered the address on the evening of the first day of the meeting, followed by a reception tendered to the Society by the Philadelphia County Medical Society. The title of the address was "Pioneer Physicians of Western Pennsylvania." Dr. Davis gave an interesting account of the perils and privations experienced by the physicians who crossed the Alleghenies in the latter part of the eighteenth century and ministered there to the sick and wounded. Many suffered death at the hands of the Indians. "The pioneer doctor," said Dr. Davis, "was often also a farmer, a minister or a school teacher. He traveled over several counties, and often made long and perilous journeys alone. But he did his duty, danger or no danger, as his successors do now."

(To be continued.)

AMERICAN PUBLIC HEALTH ASSOCIATION.

Twenty-ninth Annual Meeting, held in Buffalo, Sept. 17-20, 1901.

President Dr. Benjamin Lee, Philadelphia, in the Chair.

There were many representatives present from the United States, Porto Rico, Canada and Mexico.

Opening Address.

Dr. Stephen Smith, New York, *one of the ex-presidents* of the Association, made the "Opening Address." He referred to the havoc which death had wrought in the ranks of the Association during the past decade, and in giving a history of the public health system of the United States said in part: "Thirty years ago there were not more than three or four well-organized municipal boards of health in this country, but to-day there is scarcely a civil organization without its department of health. Within a single decade this Association has been largely instrumental in the development of a complete system of public health administration in this country, namely, municipal, state and national. A national board of health, which was at one time established by Congress, existed but four years, and for *twenty years we have been without* such a body chiefly because of a want of *harmony among those* who approach Congress on the subject."

Dr. Smith then referred to the early history of the Marine-Hospital Service, saying that it was originally created at the close of the eighteenth century in imitation of the English system, when the sailor's home was on the sea, but since the steamship has supplanted the sailing vessel, the sailor's home is at the port. All great advances, he said, in health legislation result from the devastation of epidemic pestilences.

Dr. A. L. Guyon, in moving a vote of thanks to Dr. Smith for his paper, drew attention to the fact that while on his right sat the Director General of Public Health of Canada, and while on his left sat the supreme head of the sanitary department of Mexico, the United States had no such officer, and that a demand should be made on the government to make such an appointment.

Out of respect to the memory of President McKinley, and in accordance with the national and state proclamations relating thereto, it was decided to hold no meeting on Thursday, Sept. 19.

Dr. Montizambert, of Ottawa, Canada, and Dr. [illegible] ingly referred to the sad [illegible] of [illegible] city, and extended the

army in 1889, it was not thoroughly established until 1892. The second period began with that year and ended with 1897. He did not quote *figures after 1897, because he did not believe the figures of the last three years of active service in the army could fairly be compared with the figures for a period in the time of peace, although he commented that, as a matter of fact, the figures for 1898, 1899 and 1900, show even a more marked improvement in those conditions of the army that* were affected by the canteen than the figures for the six years immediately preceding 1892 showed over the precanteen period from 1885 to 1891. The paper showed that for the ten years *from 1878 to 1887 the ratio of soldiers entered upon the sick reports for alcoholism* was as 64.28 to 1000; that this rate was diminished as the canteen was gradually introduced, and that comparing the period of 1885-91 to the period of 1892-97, the statistics showed a reduction of 23.6 per cent. in the entries *for alcoholism on the sick list, in favor of the latter* period. That, whereas, in 1890, before the canteen was fairly established, the number of posts at which the alcoholism entries on the sick list exceeded 10 per cent. of the total strength *of the garrison, in the following year the number of such posts* was 11, *and each succeeding year the number* was reduced until, in 1897, there were only two posts throughout the army which showed *a* greater rate of alcoholic sick cases than 10 per cent. of their total strength. The author showed that the *gravity of the cases of alcoholism* also was reduced through the influence of the canteen, and that the number of cases of insanity diminished during the period in which the canteen was thoroughly established.

The profits of the canteen each year were returned to the men for the purpose of buying better *food, reading matter*, gymnasium and athletic equipment, and in other ways to make their lives more comfortable and the military service more attractive. The writer showed that during the period of 1892-1897 there was *an increase* of 13.3 per cent. in the number of soldiers *making* deposits with the army paymaster over the number for the precanteen period, 1886-91. Also that the average number of convictions by court marshals for drunkenness during the precanteen period was 372 a year, whereas the average number after the canteen was established was but 160.

Much might be said to show the remarkable influence which the canteen, with its restricted sale of beer and light wines, has had in preserving the health of troops, maintaining discipline and promoting temperance; but in view of the figures given further argument on the subject would seem unnecessary. The canteen, as formerly operated, was a positive element for good, and so regarded by 95 per cent. of the more than 600 officers of the army who have made reports concerning its influence to the Secretary of War.

At the conclusion of Dr. Munson's paper, the following resolution was offered by Dr. Charles A. Lindsley, of New Haven, Conn., which was adopted:

Resolved, That this body deplores any action in curtailing the operation of the army canteens or post exchanges, and in the interest of general and military sanitation and temperance recommends their establishment as formerly existing in the United States.

Dr. Charles R. Greenleaf, *army surgeon*, described the sanitary conditions in the Philippine Islands since the United States came into occupancy of them.

Tuberculosis.

Dr. Felix Formento, New Orleans, stated that the discovery of the tubercle bacillus was one of the greatest events of *modern* medicine, unifying into one classification many affec- [illegible] ed as being of a different character; also making [illegible] certain; it was shown that the disease [illegible] an to man; that the sputum of con- [illegible] of infection; but was it not [illegible] is was only transmissible [illegible] no part in this trans- [illegible] shown that [illegible] a powerful [illegible] to

Incudectomy in Progressive Hardness of Hearing, Tinnitus Aurium and Ear Vertigo.

Dr. Charles H. Burnett, Philadelphia, stated that in this disease the surgeon encountered a trophoneurosis of the muscular structures of the middle ear, and not simply a chronic catarrhal process. The chronic catarrnal process often accompanies symptoms of progressive hardness of hearing and tympanic vertigo. The aural symptoms, however, often remain unchanged when the catarrhal symptoms have been relieved. The aural symptoms were outlined. Progressive hardness of hearing is apt to pass from one ear to the other. The treatment advised by Dr. Burnett is the removal of the incus from the worse ear, leaving the remaining conductors in place. The difficulty of the operation necessitates the etherization of the patient. Dr. Burnett's cases show the efficiency of the operation in checking the progress of deafness and in the total and permanent arrest of ear vertigo.

Reasons for Early Operation in Acute Mastoiditis.

Dr. William H. Dudley, Easton, stated that there is a variety of acute mastoiditis, usually a sequel to chronic purulent otitis media, which at no time presents any serious local symptoms. In some of these cases the swelling may be moderate in amount, the tinnitus not great and at no time is there great pain or other general disturbance; yet, when given sufficient time, so extensive may the disease become as to seriously threaten the patient's life. Cases illustrative of this condition were cited. Aside from the intractable chronic otitis media purulenta which may follow these cases, if the condition is allowed to continue, there may ensue extradural abscess, meningitis, cerebral abscess or septic thrombosis of the lateral sinus with their attendant fatalities. He believed that the dangers attending mastoiditis not operated upon in the early stages have not been sufficiently impressed upon the mind of the profession.

Dr. B. Alexander Randall, Philadelphia, believed that many of the mastoid inflammations were not purulent and do not need operative intervention; at least four out of five cases of redness, swelling and tenderness of the mastoid, in his experience, did not require operation, but would clear up under proper medication and rest.

Dr. Burnett stated his belief that operation was indicated in the presence of one or more of the three symptoms: pain, pyrexia or prolapse in the posterior upper portion of the auditory canal. He referred to the paper of Dr. Shepherd, of Brooklyn, on "Acute Mastoiditis following Acute Otitis Media," which he considered one of the best he had ever read.

Ocular Affections of Childhood Associated with Impaired General Nutrition.

Dr. S. D. Risley, Philadelphia, gave briefly the clinical history of two cases to illustrate the form of ocular disease frequently occurring during adolescence, but not necessarily dependent upon the peculiar conditions of vitality at that age. He gave a graphic picture of the general conditions. In conclusion he called attention to the important influence the trials of school life when associated with headache and painful hot eyes due to eye strain from abnormal refraction may have over the general health of the child.

Gumma of the Ciliary Body.

Dr. Edward Stieren, Pittsburg, in this paper remarked that syphilitic invasion of the deeper parts of the eye, especially the acquired form, usually calls for a guarded prognosis. A detailed report of an apparently hopeless case was given. When the patient was first seen in 1899 the diagnosis of tertiary syphilis was made. When last seen, on July 19, 1901, the only evidence of the gumma was a slaty discoloration of the sclera and the misplaced pupil.

Contagious Diseases of the Eye and Their Treatment.

Dr. S. Lewis Ziegler, Philadelphia, said that the successful treatment of contagious disease of the eye presupposed an early recognition of the symptoms and the prompt application of active measures for relief. The contagious diseases were classified under catarrhal ophthalmia, and purulent ophthalmia. He spoke briefly of acute catarrhal and granular conjunctivitis. In these prophylaxis should play an important part. If one eye alone is affected a separate handkerchief should be used for each eye. The local treatment for both conditions was described. The purulent inflammations were detailed with their symptoms. The discharges of the purulent inflammations are usually septic in character and extremely virulent in action. Instructions which should be given the attendant are outlined. The most successful local prophylactic measures in the treatment of ophthalmia neonatorum he said were limited to three: 1, Credé's ointment; 2, the irrigation of the eyes with a solution of mercuric bichlorid, 1 to 4000; 3, a solution of protargol in strength of from 10 to 25 per cent.

Address in Mental Disorders.

Dr. Robert H. Chase, Superintendent of the Friends' Asylum for the Insane at Frankford, Philadelphia, took for his subject, "Paresis from the Standpoint of the General Practitioner." Its importance was brought to the attention of the general physician and his responsibility pointed out. The initial stage should be intelligently studied for speedy recognition of the disease, and because it is often the only time when treatment is successful. The history of the disease was given, and the following prominent theories respecting its nature briefly stated: 1, as a complication of insanity; 2, as a distinct form of insanity; 3, if not as a group of cerebral or cerebrospinal affections, at least as a paralytic dementia, to which is associated more or less frequently, and under various conditions, insanity.

Progressive Muscular Dystrophy in Brother and Sister.

Dr. A. A. Eshner, Philadelphia, reported these cases in a brother and sister, aged respectively 13 and 32. The cases were interesting particularly because of their occurrence in two members of the same family, of the history of another dystrophy in the collateral ancestry, and of the presence of a traumatic cerebral disorder in the father. The most plausible explanation of the lesions, the author said, was that attributing them to some developmental defect, resulting in the replacement of muscular by fatty and fibrous tissue, with secondary motor disability and the consequent deformities. The disorder is usually progressive, with unfavorable prognosis. Massage and electricity were mentioned as possible aids in the preservation of undestroyed muscular tissue and in the prevention of deformities. Surgical treatment may be indicated, and mechanical measures may be employed to aid locomotion.

Prognosis in Neuritis.

Dr. F. Savary Pearce, Philadelphia, said that in summing up scientific clinical facts of carefully studied cases of neuritis there would be found to exist signs and symptoms indicating the ultimate results in different classes of cases depending upon the pathogenic findings, the variety of cases, etc. The etiology of the case is so closely interwoven with symptomatology and with true foresight or prognosis, indeed, that not anything like definite results can be prognosticated until the cause is determined. Examples of needle prick and gunshot wounds, as affecting nerve tissue badly, were stated. The prognosis in such traumatic cases is usually very grave. Cases were referred to exemplifying this. It was pointed out that pressure neuritis should be differentiated from the palsies of occupation neuritis in which latter there is usually a central cortical asthenia; the local disability will depend upon the cure of the primary. In the ordinary pressure neuritis the prognosis is good. Predisposition by alcoholism should be borne in mind in these cases. Degeneration of peripheral nerve trunks after severance was spoken of; also diathetic causes of neuritis. Reference was made to the gastro-intestinal tract as of importance in the correction of disorder in this part of the body.

Some Cases of Hysteria.

Dr. Edward E. Mayer, Pittsburg, emphasized the statement that hysteria is always a psychic disease; and, that the various symptoms are but the result of this primary mental con-bluish green. The lower posterior portion of the lobe was completely consolidated; pleura, of a light pinkish color, had lost its luster and contained subpleural hemorrhages. Cut surface of the consolidated portion is rich in blood, light pinkish color. Pressure caused blood, but no air or serum to exude. The appearance does not bear any resemblance to any stage of croupous pneumonia. No tubercles present.

Spleen.—Enlarged to about one and a half times normal size; capsule wrinkled, moderately firm in consistence; color not very red; no white nodules subcapsular, cuts a little firmer than normal. Connective tissue increased; cut surface moderately rich in blood; pulp slightly bulging.

Liver.—Gall-bladder moderately distended, contained no stones. Liver about normal or slightly smaller in size, surface smooth and glistening, of a light chocolate color. Normal in consistence, cut surface moderately rich in blood.

Kidneys.—Left: smaller than normal, soft, fatty capsule well preserved; capsule stripped readily, exposing a light yellowish surface, mottled with red, which was not granular, in which the venæ stellatæ showed prominently. Cut surface rich in blood. Contrast between cortex and pyramids well preserved. Cortical margin normal in breadth; same color or a little deeper than described on surface. Left kidney same as right.

Stomach.—Mucous membrane showed a few submucous hemorrhages. Smears from the spleen and blood did not show any organisms.

Animals inoculated from the glands of the bubo died of typical plague infection.

NEW CASES.

Ng Chon was seen at 821 Washington Street, September 11, by Dr. Kellogg, the city bacteriologist. According to the representations of inmates of the house, he had been sick one week. The Doctor found him with a temperature of 104, pulse 120, with a dry mouth and coated tongue. There was a large bubo in the right femoral region. No evidence of venery. No microscopical examination of fluid from the bubo nor blood allowed. He was removed to the plague hospital and is recovering.

Alexander Winters, a sailor, came from a ship in the harbor. He was taken sick on September 11, on board ship, with vomiting and chills; a bubo developed at the same time in the right femoral region. He came ashore and entered a lodging-house at 812 Third Street, where he remained for two days. He then applied at the Marine-Hospital where he was admitted and where he now is. There was no evidence of venereal disease in his case. Blood taken from the bubo gave a pure culture of the bacillus pestis. The results of animal inoculation are not completed.

Association News.

Nicholas Senn Prize Medal.

The committee on the Senn Medal beg leave to call attention to the following conditions governing the competition for this medal for 1902:

1. A gold medal of suitable design is to be conferred upon the member of the American Medical Association who shall present the best essay upon some surgical subject.

2. This medal will be known as the Nicholas Senn Prize Medal.

3. The award will be made under the following conditions: *a*. The name of the author of each competing essay shall be enclosed in a sealed envelope bearing a suitable motto or device, the essay itself bearing the same motto or device. The title of the successful essay and the motto or device is to be read at the meeting at which the award is made, and the corresponding envelope to be then and there opened and the name of the successful author announced. *b*. All successful essays become the property of the Association. *c*. The medal shall be conferred and honorable mention made of the two other essays considered worthy of this distinction, at a general meeting of the Association. *d*. The competition is to be confined to those who at the time of entering the competition, as well as at the time of conferring the medal, shall be members of the American Medical Association. *e*. The competition for the medal will be closed three months before the next annual meeting of the American Medical Association, and no essays will be received after March 1, 1902.

Communications may be addressed to any member of the committee, consisting of the following: Dr. Herbert L. Burrell, 22 Newbury Street, Boston, Mass.; Dr. Edward Martin, 415 S. 15th Street, Philadelphia, Pa.; Dr. Charles H. Mayo, Rochester, Minn.

Married.

Thomas J. O'Malley, M.D., to Miss Helen M. Ahern, both of Joliet, Ill., July 10.

T. A. Hudson, M.D., Olive, Tex., to Miss Mattie De Arman, Hico, Tex., September 10.

James Patrick Moore, M.D., to Miss Elizabeth Taylor, both of Yazoo City, Miss., October 2.

Joseph E. Gardner, M.D., Fort Worth, Tex., to Miss Rose Montague, at Bandera, Tex., September 11.

A. E. Myers, M.D., Jamestown, N. Y., to Miss Jessie E. Beacon, Randolph, N. Y., September 18, at the home of the bride.

Henry Blankenhorn, M.D., Orrville, Ohio, to Miss Mabel Buckley, Marshallville, Ohio, September 26, at the home of the bride.

Deaths and Obituaries.

Charles H. Guibor, M.D., Rush Medical College, Chicago, 1871, died at his home in Topeka, Kan., September 22, from intestinal obstruction following an operation for carcinoma, aged 59. He was born in St. Louis, Mo., and first practiced in Iowa Falls, Iowa, moving to Kansas in 1875, where he took up his practice at Beloit, remaining there until 1889, when he removed to Topeka. He was a member of the Kansas Board of Medical Examiners for a number of years.

Albrecht H. Trapp, M.D., University of Zurich, Switzerland, died at Lincoln, Ill., September 23, aged 88. He was born in Germany and came to this country in 1837, owing to political differences. For forty years he was an active practitioner at Springfield, Ill., and was elected to the State Legislature in 1854. He always took an active interest in educational affairs.

Enoch Callaway, A.M., M.D., Jefferson Medical College, Philadelphia, 1876, A.B., and A.M., Mercer University, Macon, Ga., died at his home in LaGrange, Ga., of Bright's disease, September 2, aged 48. He was a member of the Medical Association of Georgia, held the position of mayor for two terms and was a prominent physician of Western Georgia.

Albert H. Frederick, M.D., New York University, 1856, died suddenly at his home in Ocala, Fla., September 23, aged 66. He was born at Cusseta, Ala., and served through the Civil war as a surgeon of the 47th Alabama Infantry. He had practiced at Ocala since 1890.

Chauncey H. Hunt, M.D., University of Vermont, Burlington, 1875, died at his home in Montpelier, Vt., September 18, after a long illness, aged 60. He practiced until ten years ago at Worcester, and in 1880 was a representative from that place to the State Legislature.

Harvey L. Cokenower, M.D., College of Physicians and Surgeons, Keokuk, 1877, died at his home in Clarinda, Iowa, September 19, from Bright's disease, aged 46. He was born in Shelby County, Illinois, and had practiced at Clarinda since 1880.

James McJames, M.D., South Carolina Medical College, Charleston, died at a hospital in Charleston, September 24, aged 27. He was a pitcher of note on the Brooklyn baseball team, although for a time he practiced medicine at Cheraw, S. C.

Simon Schoonmaker, M.D., University of Toronto, 1857, York, died at his home at Pine Hill, N. Y., September 18, aged 64. He practiced for twenty years at Rosendale, but of late years he had not been in active practice.

Thomas W. McCoy, M.D., University of Nashville, Nashville, 1855, died at his home in Laurens, S. C., September 25, after a short illness, aged 70. He served as a surgeon in the confederate army during the Civil war.

Jeremiah S. Trexler, M.D., University of Pennsylvania, Philadelphia, 1853, died at his home in Kutztown, Pa., September 24, aged 74. During the Civil war he was surgeon in the 73d Pennsylvania Volunteers.

Hiram M. Winn, M.D., College of Physicians and Surgeons, Keokuk, 1892, died at Lawton, Oklahoma, September 20, from typhoid fever, aged 50. At one time he practiced in Louisville, Ky.

George M. Morse, M.D., Harvard University Medical School, Boston, 1843, died at his home in Clinton, Mass., where he had practiced for the past fifty-five years, September 23, aged 80.

William B. Harper, M.D., Tulane University, New Orleans, 1885, died at his home in Minden, La., as the result of an apoplectic stroke, September 23, aged 50.

David McKinney, M.D., Jefferson Medical College, Philadelphia, 1860, died at his home in New Brighton, Pa., September 20, after a long illness, aged 72.

George C. Shannon, M.D., University of Toronto, 1857, died at his home in Goderich, Ont., September 8, aged 68. He practiced in Goderich for forty years.

William F. Pratt, M.D., Medical Department Queen's University, Kingston, Ont., 1888, died at his home in Ottawa, Ont., September 19.

Franklin A. Handrick, M.D., Jefferson Medical College, Philadelphia, 1894, died suddenly at his home in Cleveland, Ohio, September 20.

Charles C. Weamer, M.D., Western Pennsylvania Medical College, Pittsburg, 1897, died at Plumville, Pa., September 12, aged 31.

Societies

COMING MEETINGS.

Tri-State Medical Society of Alabama, Georgia and Tennessee. Nashville, Tenn., Oct. 8-10, 1901.

Wyoming State Medical Society, Evanston, Oct. 8-9, 1901.

Vermont State Medical Society, Montpelier, Oct. 10-11, 1901.

New York State Medical Association, New York City, Oct. 21-24, 1901.

Medical Society of Virginia, Lynchburg, Nov. 5-7, 1901.

Oklahoma Territory Medical Association, Oklahoma City, Nov 13, 1901.

Southern Surgical and Gynecological Association, Richmond, Va., Nov. 19, 1901.

Medical Club of Philadelphia.—A reception was given at the Hotel Stratford by this Club, September 26, in honor of the president and members of the Medical Society of the State of Pennsylvania.

Kern County (Cal.) Medical Society.—At Bakersfield, September 12, this Society was organized, and officers were elected as follows: Dr. Thaddeus W. Helm, president; Dr. D. J. Prather, vice-president, and Dr. W. S. Fowler, secretary-treasurer.

Claiborne County (Tenn.) Medical Society.—This Society was organized at Tazewell, September 10, and the following officers elected: President, Dr. George P. Miller; vice-president, Dr. M. G. Walker, and secretary-treasurer, Dr. George P. Lynch.

Northern Berkshire Medical Society.—At the annual meeting of this Society, held at North Adams, Mass., September 24, the following officers were elected: Dr. John H. Riley, president; Dr. Edward E. Russell, vice-president, and Dr. Lyman A. Jones, secretary and treasurer.

American Electro-Therapeutic Association.—The eleventh annual session of this Association was held in Buffalo, September 24, 25 and 26. There were fifty-five delegates in attendance and an excellent meeting was enjoyed. Besides many interesting papers by members, the superintendent of electricity at the Exposition delivered an address.

Philadelphia County (Pa.) Medical Society.—A special meeting of this Society was held in Philadelphia, September 19, for the purpose of organizing a branch society. A permanent organization was effected, to cover the northern portion of the city, the idea being to make more accessible the society meetings to those living some distance from the meeting place to the main body. Dr. H. Brooker Mills was elected permanent chairman, and Dr. Robert L. Pitfield, secretary.

Missouri State and County Board of Health.—The State Board of Health organized with about twenty County Boards at a meeting held in Sedalia, September 10, by the election of the following officers: President, Dr. A. W. McAllister, Columbia; vice-president, Dr. W. F. Morrow, Kansas City, and corresponding secretary, Dr. J. R. Graham, St. Joseph. The object of the organization is to encourage a harmonious working of the State and County Boards, especially in the matter of controlling contagious diseases.

The Fifth International Congress of Zoology.—The principal features of this Congress which convened at Berlin, August 19, were Grassi's detailed report of the Italian Society for the study of malaria and what it has accomplished, and Schenk's communication on the results of his method of sex determination. He claims that time is confirming the correctness of his views, and that his array of cases in which sex was determined by his method of preliminary treatment, is so long and so extensive that the idea of mere coincidence must be definitely abandoned. The profession abroad not only refuse to accept his premises, but state that even if they were true their promulgation would be a social calamity.

Medical Society of the Missouri Valley.—The fourteenth annual meeting of this Society was held in St. Joseph, Mo., September 19, with President Treynor in the chair. After passing resolutions on the death of the President, the Society adjourned to permit its members to attend the McKinley memorial services. On the evening of September 19 an adjournment to Eureka Springs, Ark., was taken, where the annual outing was enjoyed and the regular program carried over from St. Joseph was continued. Following is the list of officers elected for the coming year: President, Dr. Richard C. Moore, Omaha; vice-presidents, Drs. A. D. Wilkinson, Lincoln, and M. F. Weymann, St. Joseph; treasurer, Dr. Donald Macrae, Council Bluffs, and secretary, Dr. Charles Wood Fassett, St. Joseph. The next meeting will be held in Lincoln, Neb., March, 1902.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Fifty-first Annual Meeting, held in Philadelphia, September 24-26, 1901.

First Day.—Morning Session.

President, Dr. Thomas D. Davis, Pittsburg, in the Chair.

Dr. George Erety Shoemaker, on behalf of the Philadelphia County Medical Society as its President, extended a welcome to the Society. He compared the position of the various societies to that of brothers annually welcoming to their homes in turn the other members of a family. In this city there is much to link us to the past in the history of medicine. Here was the life work of many of the leaders who have molded medical thought for generations. From their traditional or direct influence a strong stimulus is yet felt. The hope was expressed that in the development of library systems some means would be found to distribute medical books widely from the central institutions, so that practitioners at a distance might be in touch with the treasures of medical literature. The President extended the thanks of the Society for the warm welcome and remarked that in coming to Philadelphia the Society felt that it was coming to a medical atmosphere.

Mayor Ashbridge extended a welcome on behalf of the city, which, he said, enjoyed not only a national but an international reputation for its skill in medicine and surgery. So far as the administration of public affairs was concerned, he said bluish green. The lower posterior portion of the lobe was completely consolidated; pleura, of a light pinkish color, had lost its luster and contained subpleural hemorrhages. Cut surface of the consolidated portion is rich in blood, light pinkish color. Pressure caused blood, but no air or serum to exude. The appearance does not bear any resemblance to any stage of croupous pneumonia. No tubercles present.

Spleen.—Enlarged to about one and a half times normal size; capsule wrinkled, moderately firm in consistence; color not very red; no white nodules subcapsular, cuts a little firmer than normal. Connective tissue increased; cut surface moderately rich in blood; pulp slightly bulging.

Liver.—Gall-bladder moderately distended, contained no stones. Liver about normal or slightly smaller in size, surface smooth and glistening, of a light chocolate color. Normal in consistence, cut surface moderately rich in blood.

Kidneys.—Left: smaller than normal, soft, fatty capsule well preserved; capsule stripped readily, exposing a light yellowish surface, mottled with red, which was not granular, in which the venæ stellatæ showed prominently. Cut surface rich in blood. Contrast between cortex and pyramids well preserved. Cortical margin normal in breadth; same color or a little deeper than described on surface. Left kidney same as right.

Stomach.—Mucous membrane showed a few submucous hemorrhages. Smears from the spleen and blood did not show any organisms.

Animals inoculated from the glands of the bubo died of typical plague infection.

NEW CASES.

Ng Chon was seen at 821 Washington Street, September 11, by Dr. Kellogg, the city bacteriologist. According to the representations of inmates of the house, he had been sick one week. The Doctor found him with a temperature of 104, pulse 120, with a dry mouth and coated tongue. There was a large bubo in the right femoral region. No evidence of venery. No microscopical examination of fluid from the bubo nor blood allowed. He was removed to the plague hospital and is recovering.

Alexander Winters, a sailor, came from a ship in the harbor. He was taken sick on September 11, on board ship, with vomiting and chills; a bubo developed at the same time in the right femoral region. He came ashore and entered a lodging-house at 812 Third Street, where he remained for two days. He then applied at the Marine-Hospital where he was admitted and where he now is. There was no evidence of venereal disease in his case. Blood taken from the bubo gave a pure culture of the bacillus pestis. The results of animal inoculation are not completed.

A permanent organization was effected, to cover the northern portion of the city, the idea being to make more accessible the society meetings to those living some distance from the meeting place to the main body. Dr. H. Brooker Mills was elected permanent chairman, and Dr. Robert L. Pitfield, secretary.

Missouri State and County Board of Health.—The State Board of Health organized with about twenty County Boards at a meeting held in Sedalia, September 10, by the election of the following officers: President, Dr. A. W. McAllister, Columbia; vice-president, Dr. W. F. Morrow, Kansas City, and corresponding secretary, Dr. J. R. Graham, St. Joseph. The object of the organization is to encourage a harmonious working of the State and County Boards, especially in the matter of controlling contagious diseases.

The Fifth International Congress of Zoology.—The principal features of this Congress which convened at Berlin, August 19, were Grassi's detailed report of the Italian Society for the study of malaria and what it has accomplished, and Schenk's communication on the results of his method of sex determination. He claims that time is confirming the correctness of his views, and that his array of cases in which sex was determined by his method of preliminary treatment, is so long and so extensive that the idea of mere coincidence must be definitely abandoned. The profession abroad not only refuse to accept his premises, but state that even if they were true their promulgation would be a social calamity.

Medical Society of the Missouri Valley.—The fourteenth annual meeting of this Society was held in St. Joseph, Mo., September 19, with President Treynor in the chair. After passing resolutions on the death of the President, the Society adjourned to permit its members to attend the McKinley memorial services. On the evening of September 19 an adjournment to Eureka Springs, Ark., was taken, where the annual outing was enjoyed and the regular program carried over from St. Joseph was continued. Following is the list of officers elected for the coming year: President, Dr. Richard C. Moore, Omaha; vice-presidents, Drs. A. D. Wilkinson, Lincoln, and M. F. Weymann, St. Joseph; treasurer, Dr. Donald Macrae, Council Bluffs, and secretary, Dr. Charles Wood Fassett, St. Joseph. The next meeting will be held in Lincoln, Neb., March, 1902.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Fifty-first Annual Meeting, held in Philadelphia, September 24-26, 1901.

First Day.—Morning Session.

President, Dr. Thomas D. Davis, Pittsburg, in the Chair.

Dr. George Erety Shoemaker, on behalf of the Philadelphia County Medical Society as its President, extended a welcome to the Society. He compared the position of the various societies to that of brothers annually welcoming to their homes in turn the other members of a family. In this city there is much to link us to the past in the history of medicine. Here was the life work of many of the leaders who have molded medical thought for generations. From their traditional or direct influence a strong stimulus is yet felt. The hope was expressed that in the development of library systems some means would be found to distribute medical books widely from the central institutions, so that practitioners at a distance might be in touch with the treasures of medical literature. The President extended the thanks of the Society for the warm welcome and remarked that in coming to Philadelphia the Society felt that it was coming to a medical atmosphere.

Mayor Ashbridge extended a welcome on behalf of the city, which, he said, enjoyed not only a national but an international reputation for its skill in medicine and surgery. So far as the administration of public affairs was concerned, he said there had been an endeavor to do the best to enlarge the opportunity of the medical student; the hospital for contagious diseases had been opened to the graduates of the colleges. The staff of the Philadelphia Hospital had been enlarged, and to medical gentlemen had been given the selection of those appointed.

Dr. John H. Musser, Chairman of the Committee on Arrangements and Credentials, presented the program, and announced that arrangements had been made for the holding of clinics.

Dr. John V. Shoemaker, Philadelphia, offered a resolution that the Society testify to the profound grief of its members at the loss of the Chief Executive of the United States, and that such resolutions be placed in the records of the Society.

Representation in the House of Delegates, A. M. A.

The Secretary, Dr. C. L. Stevens, reported a total membership of 3460. This was a net increase of 110. This membership entitled the Society to seven delegates in the House of Delegates in the American Medical Association, lacking only 41 members of the number entitling the Society to a representation of eight delegates; this number he hoped would be realized by June, 1902.

Dr. E. E. Montgomery, Philadelphia, moved that the Nominating Committee be directed to select and nominate seven delegates from the Society to the House of Delegates of the American Medical Association, four for two years and three for one; also sixteen alternates; it to be understood that the first alternate take the office of the eighth delegate if by June, 1902, the Society should be entitled, as there was reason to hope, to the eighth delegate. The resolution was seconded and adopted.

The report of the Board of Trustees showed that the financial affairs of the Society had been prosperous and that no unusual expense had been incurred.

It was with sincere regret that the Board reported the death of Dr. John Curwen, long a most respected and useful member of the Society; once the President, and at the time of his death a member of the Board of Trustees.

The Committee on Publication reported that 4000 copies of The Journal of the State Medical Society had been published each month, of which about 2500 were distributed monthly to the members of the auxiliary county societies. The advertising pages had been made to conform strictly to the requirements of the Code of Ethics.

Reports of Committees.

The Committee on Pharmacy called attention to the prevalent abuse of hospital and dispensary clinics by patients able to pay for professional services, and recommended that the legislature be asked to pass an act requiring all persons seeking such aid to record their names and addresses, and when unable to write, make their marks, as is customary in legal documents, in a book kept for the purpose, which shall be open to inspection by proper persons, and if possible inflict a penalty upon those who fraudulently receive aid. The use of tablets in set formula was also deprecated.

The Committee on the Rush Monument Fund regretted to report that nothing had been done by the Committee since the meeting at Lancaster.

The Committee on Increase of Membership and Polyclinic Teaching reported an increase of 110 members in the Society. Thirty-one societies have a larger membership than last year and 14 had lost in membership during the year. The Committee suggested that personal visitation is needed in societies lacking vitality. This had proven of value in some individual societies.

The Committee on Archives announced the death of Dr. J. Augustus Ehler of Lancaster, Pa. Dr. Ehler had taken an active interest in the Society from its inception, having been one of the founders. He was particularly energetic in the committee work and most anxious that all matters pertaining to the history of the organization be placed in a convenient locality for consultation by members. The Committee further reported that the cataloguing of volumes deposited in the Library of the University of Pennsylvania had been continued.

The Committee on Examination of School Text-Books reported progress. Two members of the Committee, Dr. Israel Cleaver of Reading, and Dr. John Fay of Allegheny, asked to be discharged. The names of Dr. G. A. Parker of Southampton, and Dr. W. A. N. Dorland of Philadelphia, were suggested to take their places.

Dr. Henry Beates, Jr., Chairman of the State Board of Medical Examiners, gave the number of graduates from the respective medical colleges who had applied for examination during the year with the percentage of success and failure. He called the attention of the Society to the fact that while great advances had been made during the period in which the law governing medical practice has been operative, yet the conditions of medical education to-day are deplorable. He expressed the hope that the Society, standing as it does as the exponent of the highest type of medical education, would assert itself in no uncertain manner in demanding the ideal.

Dr. John B. Roberts, Philadelphia, Delegate to the Conference on National Legislation of the American Medical Association, reported that the annual conference was held on February 20, 1901, in Washington, and read a brief report of the results of the meeting.

The President contributed a Minute concerning the late Dr. Samuel S. Towler. Dr. Towler was widely known and very successful in his practice. As a matter of conscience he answered all calls, no matter how wearisome or unremunerative. He was the soul of generosity, always having a cordial greeting for all. As a citizen and a business man he had the confidence of all who knew him, and was prominent in Christian work.

Directory of Physicians for the State.

Dr. John B. Roberts offered a resolution that the Committee on Publication, in conjunction with the Board of Trustees, consider the propriety of publishing a Directory of the physicians of Pennsylvania similar to the Directory published by the New York Medical Association; and, that if the said Committee and the Board of Trustees deem it wise to publish such a Directory, that authority is hereby given for such publication. The resolution was approved and referred to the proper committee.

FIRST DAY.—AFTERNOON SESSION.

Address in Otology.

Dr. E. U. Buckman, Wilkesbarre, noted some changes that have taken place in the progress of otology in the last six years. In the beginning of Dr. Buckman's practice of otology mastoiditis was looked upon with considerable dread, but the present methods of radical operation are so successful, and in skilful hands attended with so little danger that now abortive treatment is not continued for any length of time. The treatment of this disease is now one of the most satisfactory procedures in the whole realm of otology. Tinnitus aurium was referred to as one of the least satisfactory conditions to treat and one in which there probably has been the least progress in the last five to twenty years. The use of electrolysis in cases of obstinate tinnitus and increasing deafness he had found beneficial. Success in the treatment of these conditions depends more upon how medicines or instruments are used than upon what is used.

Some Aural Complications of Influenza.

Dr. S. MacCuen Smith, Philadelphia, stated that influenza has been recognized and treated as such for ages, the epidemics having always been characterized by intervening periods during which the disease seems to have been banished. Brief mention was made of mastoid complications, counseling their early recognition and the adoption of energetic measures for relief of local symptoms and the prevention of additional complication of even more serious import.

Dr. Charles H. Burnett, Philadelphia, in discussion, said that when the so-called epidemics of grip or influenza broke out in 1889 he had been practicing otology seventeen years and he had never seen any case of so-called grip presenting symptoms which he had not seen previous to the spread of this affection. The hemorrhagic form he did not think any more prevalent in grip than in measles. He believed there was no specific excitant in the attacks of grip or influenza.

Incudectomy in Progressive Hardness of Hearing, Tinnitus Aurium and Ear Vertigo.

Dr. Charles H. Burnett, Philadelphia, stated that in this disease the surgeon encountered a trophoneurosis of the muscular structures of the middle ear, and not simply a chronic catarrhal process. The chronic catarrnal process often accompanies symptoms of progressive hardness of hearing and tympanic vertigo. The aural symptoms, however, often remain unchanged when the catarrhal symptoms have been relieved. The aural symptoms were outlined. Progressive hardness of hearing is apt to pass from one ear to the other. The treatment advised by Dr. Burnett is the removal of the incus from the worse ear, leaving the remaining conductors in place. The difficulty of the operation necessitates the etherization of the patient. Dr. Burnett's cases show the efficiency of the operation in checking the progress of deafness and in the total and permanent arrest of ear vertigo.

Reasons for Early Operation in Acute Mastoiditis.

Dr. William H. Dudley, Easton, stated that there is a variety of acute mastoiditis, usually a sequel to chronic purulent otitis media, which at no time presents any serious local symptoms. In some of these cases the swelling may be moderate in amount, the tinnitus not great and at no time is there great pain or other general disturbance; yet, when given sufficient time, so extensive may the disease become as to seriously threaten the patient's life. Cases illustrative of this condition were cited. Aside from the intractable chronic otitis media purulenta which may follow these cases, if the condition is allowed to continue, there may ensue extradural abscess, meningitis, cerebral abscess or septic thrombosis of the lateral sinus with their attendant fatalities. He believed that the dangers attending mastoiditis not operated upon in the early stages have not been sufficiently impressed upon the mind of the profession.

Dr. B. Alexander Randall, Philadelphia, believed that many of the mastoid inflammations were not purulent and do not need operative intervention; at least four out of five cases of redness, swelling and tenderness of the mastoid, in his experience, did not require operation, but would clear up under proper medication and rest.

Dr. Burnett stated his belief that operation was indicated in the presence of one or more of the three symptoms: pain, pyrexia or prolapse in the posterior upper portion of the auditory canal. He referred to the paper of Dr. Shepherd, of Brooklyn, on "Acute Mastoiditis following Acute Otitis Media," which he considered one of the best he had ever read.

Ocular Affections of Childhood Associated with Impaired General Nutrition.

Dr. S. D. Risley, Philadelphia, gave briefly the clinical history of two cases to illustrate the form of ocular disease frequently occurring during adolescence, but not necessarily dependent upon the peculiar conditions of vitality at that age. He gave a graphic picture of the general conditions. In conclusion he called attention to the important influence the trials of school life when associated with headache and painful hot eyes due to eye strain from abnormal refraction may have over the general health of the child.

Gumma of the Ciliary Body.

Dr. Edward Stieren, Pittsburg, in this paper remarked that syphilitic invasion of the deeper parts of the eye, especially the acquired form, usually calls for a guarded prognosis. A detailed report of an apparently hopeless case was given. When the patient was first seen in 1899 the diagnosis of tertiary syphilis was made. When last seen, on July 19, 1901, the only evidence of the gumma was a slaty discoloration of the sclera and the misplaced pupil.

Contagious Diseases of the Eye and Their Treatment.

Dr. S. Lewis Ziegler, Philadelphia, said that the successful treatment of contagious disease of the eye presupposed an early recognition of the symptoms and the prompt application of active measures for relief. The contagious diseases were classified under catarrhal ophthalmia, and purulent ophthalmia. He spoke briefly of acute catarrhal and granular conjunctivitis. In these prophylaxis should play an important part. If one eye alone is affected a separate handkerchief should be used for each eye. The local treatment for both conditions was described. The purulent inflammations were detailed with their symptoms. The discharges of the purulent inflammations are usually septic in character and extremely virulent in action. Instructions which should be given the attendant are outlined. The most successful local prophylactic measures in the treatment of ophthalmia neonatorum he said were limited to three: 1, Credé's ointment; 2, the irrigation of the eyes with a solution of mercuric bichlorid, 1 to 4000; 3, a solution of protargol in strength of from 10 to 25 per cent.

Address in Mental Disorders.

Dr. Robert H. Chase, Superintendent of the Friends' Asylum for the Insane at Frankford, Philadelphia, took for his subject, "Paresis from the Standpoint of the General Practitioner." Its importance was brought to the attention of the general physician and his responsibility pointed out. The initial stage should be intelligently studied for speedy recognition of the disease, and because it is often the only time when treatment is successful. The history of the disease was given, and the following prominent theories respecting its nature briefly stated: 1, as a complication of insanity; 2, as a distinct form of insanity; 3, if not as a group of cerebral or cerebrospinal affections, at least as a paralytic dementia, to which is associated more or less frequently, and under various conditions, insanity.

Progressive Muscular Dystrophy in Brother and Sister.

Dr. A. A. Eshner, Philadelphia, reported these cases in a brother and sister, aged respectively 13 and 32. The cases were interesting particularly because of their occurrence in two members of the same family, of the history of another dystrophy in the collateral ancestry, and of the presence of a traumatic cerebral disorder in the father. The most plausible explanation of the lesions, the author said, was that attributing them to some developmental defect, resulting in the replacement of muscular by fatty and fibrous tissue, with secondary motor disability and the consequent deformities. The disorder is usually progressive, with unfavorable prognosis. Massage and electricity were mentioned as possible aids in the preservation of undestroyed muscular tissue and in the prevention of deformities. Surgical treatment may be indicated, and mechanical measures may be employed to aid locomotion.

Prognosis in Neuritis.

Dr. F. Savary Pearce, Philadelphia, said that in summing up scientific clinical facts of carefully studied cases of neuritis there would be found to exist signs and symptoms indicating the ultimate results in different classes of cases depending upon the pathogenic findings, the variety of cases, etc. The etiology of the case is so closely interwoven with symptomatology and with true foresight or prognosis, indeed, that not anything like definite results can be prognosticated until the cause is determined. Examples of needle prick and gunshot wounds, as affecting nerve tissue badly, were stated. The prognosis in such traumatic cases is usually very grave. Cases were referred to exemplifying this. It was pointed out that pressure neuritis should be differentiated from the palsies of occupation neuritis in which latter there is usually a central cortical asthenia; the local disability will depend upon the cure of the primary. In the ordinary pressure neuritis the prognosis is good. Predisposition by alcoholism should be borne in mind in these cases. Degeneration of peripheral nerve trunks after severance was spoken of; also diathetic causes of neuritis. Reference was made to the gastro-intestinal tract as of importance in the correction of disorder in this part of the body.

Some Cases of Hysteria.

Dr. Edward E. Mayer, Pittsburg, emphasized the statement that hysteria is always a psychic disease; and, that the various symptoms are but the result of this primary mental condition. The treatment advised is a psychic one, mental or suggestive therapeutics being necessary. A number of cases were described.

President's Address.

Dr. Thomas D. Davis delivered the address on the evening of the first day of the meeting, followed by a reception tendered to the Society by the Philadelphia County Medical Society. The title of the address was "Pioneer Physicians of Western Pennsylvania." Dr. Davis gave an interesting account of the perils and privations experienced by the physicians who crossed the Alleghenies in the latter part of the eighteenth century and ministered there to the sick and wounded. Many suffered death at the hands of the Indians. "The pioneer doctor," said Dr. Davis, "was often also a farmer, a minister or a school teacher. He traveled over several counties, and often made long and perilous journeys alone. But he did his duty, danger or no danger, as his successors do now."

(To be continued.)

AMERICAN PUBLIC HEALTH ASSOCIATION.

Twenty-ninth Annual Meeting, held in Buffalo, Sept. 17-20, 1901.

President Dr. Benjamin Lee, Philadelphia, in the Chair.

There were many representatives present from the United States, Porto Rico, Canada and Mexico.

Opening Address.

Dr. Stephen Smith, New York, one of the ex-presidents of the Association, made the "Opening Address." He referred to the havoc which death had wrought in the ranks of the Association during the past decade, and in giving a history of the public health system of the United States said in part: "Thirty years ago there were not more than three or four well-organized municipal boards of health in this country, but to-day there is scarcely a civil organization without its department of health. Within a single decade this Association has been largely instrumental in the development of a complete system of public health administration in this country, namely, municipal, state and national. A national board of health, which was at one time established by Congress, existed but four years, and for twenty years we have been without such a body chiefly because of a want of harmony among those who approach Congress on the subject."

Dr. Smith then referred to the early history of the Marine-Hospital Service, saying that it was originally created at the close of the eighteenth century in imitation of the English system, when the sailor's home was on the sea, but since the steamship has supplanted the sailing vessel, the sailor's home is at the port. All great advances, he said, in health legislation result from the devastation of epidemic pestilences.

Dr. A. L. Guyon, in moving a vote of thanks to Dr. Smith for his paper, drew attention to the fact that while on his right sat the Director General of Public Health of Canada, and while on his left sat the supreme head of the sanitary department of Mexico, the United States had no such officer, and said that a demand should be made on the government to make such an appointment.

Out of respect to the memory of President McKinley, and in accordance with the national and state proclamations relating thereto, it was decided to hold no meeting on Thursday, September 19.

Dr. Frederick Montizambert, of Ottawa, Canada, and Dr. Eduardo Liceaga, of Mexico, feelingly referred to the sad event which had just culminated in this city, and extended the sympathy of themselves and their countrymen.

Some Results of the Army Canteen or Post Exchange From the Standpoint of Discipline and Hygiene.

Captain Edward L. Munson, assistant surgeon in the United States Army, read statistics he had compiled from the official records of the War Department, comparing the figures of two periods. The first period, which he called the precanteen period, consisted of the seven years from 1885 to 1891, inclusive. Though the canteen was first introduced in the army in 1889, it was not thoroughly established until 1892. The second period began with that year and ended with 1897. He did not quote figures after 1897, because he did not believe the figures of the last three years of active service in the army could fairly be compared with the figures for a period in the time of peace, although he commented that, as a matter of fact, the figures for 1898, 1899 and 1900, show even a more marked improvement in those conditions of the army that were affected by the canteen than the figures for the six years immediately preceding 1892 showed over the precanteen period from 1885 to 1891. The paper showed that for the ten years from 1878 to 1887 the ratio of soldiers entered upon the sick reports for alcoholism was as 64.28 to 1000; that this rate was diminished as the canteen was gradually introduced, and that comparing the period of 1885-91 to the period of 1892-97, the statistics showed a reduction of 23.6 per cent. in the entries for alcoholism on the sick list, in favor of the latter period. That, whereas, in 1890, before the canteen was fairly established, the number of posts at which the alcoholism entries on the sick list exceeded 10 per cent. of the total strength of the garrison, in the following year the number of such posts was 11, and each succeeding year the number was reduced until, in 1897, there were only two posts throughout the army which showed a greater rate of alcoholic sick cases than 10 per cent. of their total strength. The author showed that the gravity of the cases of alcoholism also was reduced through the influence of the canteen, and that the number of cases of insanity diminished during the period in which the canteen was thoroughly established.

The profits of the canteen each year were returned to the men for the purpose of buying better food, reading matter, gymnasium and athletic equipment, and in other ways to make their lives more comfortable and the military service more attractive. The writer showed that during the period of 1892-1897 there was an increase of 13.3 per cent. in the number of soldiers making deposits with the army paymaster over the number for the precanteen period, 1886-91. Also that the average number of convictions by court marshals for drunkenness during the precanteen period was 372 a year, whereas the average number after the canteen was established was but 160.

Much might be said to show the remarkable influence which the canteen, with its restricted sale of beer and light wines, has had in preserving the health of troops, maintaining discipline and promoting temperance; but in view of the figures given further argument on the subject would seem unnecessary. The canteen, as formerly operated, was a positive element for good, and so regarded by 95 per cent. of the more than 600 officers of the army who have made reports concerning its influence to the Secretary of War.

At the conclusion of Dr. Munson's paper, the following resolution was offered by Dr. Charles A. Lindsley, of New Haven, Conn., which was adopted:

Resolved, That this body deplores any action in curtailing the operation of the army canteens or post exchanges, and in the interest of general and military sanitation and temperance recommends their establishment as formerly existing in the United States.

Dr. Charles R. Greenleaf, army surgeon, described the sanitary conditions in the Philippine Islands since the United States came into occupancy of them.

Tuberculosis.

Dr. Felix Formento, New Orleans, stated that the discovery of the tubercle bacillus was one of the greatest events of modern medicine, unifying into one classification many affections considered as being of a different character; also making diagnosis perfectly certain; it was shown that the disease was communicable from man to man; that the sputum of consumptives was the great carrier of infection; but was it not going too far to affirm that tuberculosis was only transmissible by contagion, and that heredity played no part in this transmission? The observation of sanitarians had shown that heredity, as in cancer and other affections, was a powerful agent of transmission. Some cases of direct transmission to the fetus in utero had been observed. Without hereditary predisposition local infection would remain sterile in the great majority of cases. The air swarmed with microbes, and those who were predisposed succumbed. In order that a seed might develop two conditions were required, an active seed, and a proper soil. The same is true of a disease germ. All debilitating causes by lowering the powers of resistance furnished a favorable nidus for the development of the tubercle bacillus. War should be waged on the bacillus, and we should try to exterminate it by all possible means, as well as destroy the sputum; the disinfection of rooms occupied by consumptives was important, and a rigid inspection of milk and meat in spite of the claims of Professor Koch. Marriage of consumptives should be prevented. All places where numbers congregate should receive special attention, and the general public, when once informed, would become a most powerful auxiliary in the crusade against tuberculosis.

Dr. Jesus Chico, of Mexico, read a paper in which he detailed some observations tending to prove that the meat and internal organs of tuberculous animals brought about the appearance of tuberculosis in the persons who ate them.

The British Congress on Tuberculosis.

Dr. Frederick Montizambert, Director General of Public Health of Canada, read a paper on this subject, in which he laid great stress on the curability of the disease, if taken in time, and all agreed in regarding human sputum as the chief medium of infection. He stated that the feature of the Congress was the address by Dr. Koch, more particularly that part dealing with the alleged non-identity of bovine and human tuberculosis, and the non-transmissibility of the disease. The feeling throughout the Congress seemed to be that the statements of Koch were made prematurely and upon insufficient data. The position of eminent authorities who criticised Dr. Koch's announcement was essentially uniform.

After the reading of Dr. Montizambert's paper, there was a general discussion on the subject of tuberculosis, which was participated in by several members of the Association.

Dr. Chico, of Mexico, read the paper of Dr. Francisco Berbaldez, on "Remarks Intended to Show the Character of Human Vaccine as a Preventive of Smallpox."

At the Tuesday evening meeting, Mr. Ansley Wilcox, Buffalo, delivered an address of welcome, in which he paid a glowing tribute of affection and respect to President McKinley.

President's Address.

Dr. Benjamin Lee said that among the problems with which the Association had to deal was that of the protection, safety and welfare of the community against the possible infection of leprosy; that the moral leper was sometimes infinitely more dangerous than the physical leper. The anarchist was the moral leper, and it was high time that we undertook to limit the spread of this, the most horrid of all infections.

The next meeting was held on Wednesday, September 18, at which time reports were read of the Committee on Pollution of Public Water Supplies, Etiology of Yellow Fever, and cases of yellow fever observed on the two coasts of the Mexican Republic, from September 17, 1900, to August 31, 1901.

Yellow Fever.

Dr. Walter Reed, Washington, D. C., said in part as follows: "We were able under strict rules of isolation to bring about an attack of yellow fever in 10 non-immune individuals out of a total of 13 by means of the bites of mosquitoes—the stagomyia fasciata—that had previously been fed with the blood of yellow fever patients during the first, second and third days of their attacks. We were thus able to establish in the most practical manner that the mosquitoes serve as the intermediate host for the parasite of yellow fever. At the same experimental station we were able to demonstrate that yellow fever can not be induced through contact with the clothing and bedding of yellow fever patients, even though these articles had been previously thoroughly soiled with the excreta of such patients."

Dr. Reed then described in detail the mosquito which carried the infection of yellow fever, as to its history, method of propagation, habitat, breeding-places, method of generation, and measures that should be taken to prevent them from infecting healthy individuals and guarding the sick against bites of these insects. He said the life of this mosquito was about five days, if deprived of water, and if a voyage at sea had consumed more than that time, the mosquitoes contained in the hold of the vessel would have perished unless they had access to water, or moisture, and the danger of infection lay not in the cargo or personal baggage, but in the individual sick with the disease. In 1901 there was a reduction of 83 per cent. in yellow fever in the City of Havana.

A paper was presented by Dr. A. H. Doty, Health Officer of the Port of New York, dealing with the practical methods of quarantine necessary in view of the changes in our belief in regard to the necessity of disinfection in yellow fever.

A recess was then taken until 3 p. m., at which time resolutions were adopted to the effect that every effort should be made by sanitarians to diminish the mortality of tuberculosis; that sufficient facts have not been offered by Professor Koch to prove that human and bovine tuberculosis are different diseases; that municipalities regulate against expectoration; that they should compel notification by physicians of cases of tuberculosis; that they should establish municipal sanatoria for the benefit of persons in families of limited means; that tenements, factories, workshops, schools and other public institutions should be inspected in order to promote cleanliness, ventilation and other sanitary conditions.

A paper was read by Dr. Georgas, covering about the same ground as the one submitted by Dr. Reed.

A general discussion of the subject of yellow fever was then indulged in by the members of the Association, and some of the members, among them Dr. Formento and Dr. Wasdin, dissented from the views expressed in the paper of Dr. Reed. They maintained that yellow fever was probably transmissible by fomites. However, Dr. Reed in his closing remarks on the subject was very sanguine of the position he had taken, and claimed that the experiments conducted in Havana were absolutely conclusive.

Several reports were submitted during the afternoon, among which was the report of the Committee on the Relation of Forestry to the Public Health, by Professor William H. Brewer, New Haven, Conn.; also a report on Bacterial Purification of Water by Freezing, by Mr. H. W. Clark, Boston, Mass. Professor S. H. Woodbridge, Boston, submitted the report of the Committee on Car Sanitation.

Dr. A. Walter Suiter, Herkimer, N. Y., read the report of the "Committee on the Cause, Prevention and Duration of Infectious Diseases." This was followed by the report of the Committee on Disinfectants and Disinfection, by Dr. Hibbert W. Hill, of Boston, Mass., after which there was a short discussion on them.

On Thursday, the third day of the meeting, there was no business transacted, but the President called the meeting to order at 10 o'clock as usual, at which time resolutions of sympathy and regret in regard to the death of the late President McKinley were passed unanimously by a rising vote.

Drs. William Bailey, of Louisville, and C. P. Wilkinson, of New Orleans, made short speeches on the resolutions, which were very appropriate and much appreciated, after which the Association adjourned until Friday morning at 10 o'clock.

Dr. Juan Brena, of Zacatecas, Mexico, read a paper on "Notes on the Necessity of Attending to the Hygiene of the Mouths of Pupils of Schools." The author stated that the bacillus of Koch had a predilection for the buccal cavity of the mouth, which favored greatly its multiplication. He said it had been demonstrated that whatever the form might be of oral sepsis, it was susceptible of causing all the phlegmoses connected with the local organism. Many cases of septic diseases of the mouth were due to the dental caries and to that alone.

Dr. Frank W. Wright, New Haven, Conn., read a paper on "The Influence of School-Life Over Health." The author said, in part, that the first principles of school hygiene were embodied in the sites for the building, construction and furniture. With proper care natural ventilation was superior to artificial ventilation. Some of the diseases affecting children were near-sightedness, diseases of the spine, disorders of the digestive system, tonsillitis, consumption and contagious diseases. Nervous diseases were not at all infrequent and affected the teachers as well as the pupils. Impure air, defective light and mental strain were the principal causes of these troubles. Many failures were due to the long hours. The exercise and refreshment taken during intermission were not of the right nature and the lunches were sometimes made up of sweets and other indigestible food.

Dr. Guzman, of Mexico, followed with a paper along the same lines, entitled "Hygiene in Its Relation to the Primary School," and among other things he said that aid to the physician must come from the teacher. In his belief teachers should be trained to help the inspecting physician so as to be able to discover diseases produced by ill-directed school-work, contagious diseases in the school, examination of the physical condition of pupils at the time of their entrance to school, and at regular intervals thereafter.

Dr. Luis G. Espinoza, of Vera Cruz, Mexico, read a paper on "Cremation in Its Relation to Sanitary Legislation." He divided the subject into three parts: 1, the merits and demerits of cremation; 2, the establishment of hygienic regulations in cemeteries, and a discussion of their respective value; 3, he concluded in favor of compulsory cremation in contagious diseases.

There were several reports of committees and a few papers which were not read, owing to lack of time, as there were no sessions held on Thursday, but these papers and reports will appear in the official proceedings of the Association.

The following officers were elected for the ensuing year: President, Dr. Henry D. Holton, Brattleboro, Vt.; first vice-president, Dr. Walter Reed, U. S. Army; second vice-president, Dr. Jesus Chico, Guanajuato, Mexico; secretary, Dr. Charles O. Probst, Columbus, Ohio; treasurer, Dr. Frank W. Wright, New Haven, Conn. New Orleans, La., was selected as the place for holding the next annual meeting, but the exact date was not determined.

SAN FRANCISCO MEDICAL SOCIETY.

Regular Meeting, held Sept. 10, 1901.

The President, Dr. George H. Evans, in the Chair.

Cardio-Vascular System in Diabetes.

Dr. George E. Ebright presented a paper on this subject. The alkalinity was said to be much diminished, especially during coma; fat was frequently increased in the blood. The red corpuscles may be broken down into a granular material and glycogen may be demonstrated in them. The number of red cells is diminished at first, because sugar in the blood draws water from the tissues into the vessels, thereby diluting the blood. Increased diuresis soon frees the blood from an excess of sugar and water and so causes concentration. Thus the blood counts will differ within wide limits.

Pericarditis occurs sometimes and the myocardium is often pale and soft, often hypertrophied and in advanced cases marked fatty degeneration is present; glycogen is present, being found between the muscular bundles. Endocarditis with valvular changes is rare.

Arteriosclerosis is seen in long-standing mild cases, but if the sugar is not constant in the urine the vessels seem to suffer less. In the train of these arterial changes follow a number of important secondary conditions. In the brain may occur apoplexies or cerebral softening. There may be transient hemiplegia, monoplegia, aphasia, vertigo of a simple form or associated with a slow pulse and syncopal or epileptiform attacks. The condition of the vessels and kidneys are likely to account for the failure of the heart and the attacks of asthma and angina pectoris. Diabetic *gangrene* is due to arteriosclerosis or to nerve changes, the former being the most potent cause. Intimately associated with the sclerosis of the vessels are the changes in the liver, pancreas and the kidneys. There are seen in these organs in the severe cases, deposits of iron pigment about the vessels due to the destruction of the red blood corpuscles. This hemochromatosis is assigned as a cause of cirrhosis of the liver and the pancreas resulting in diabetes. Cirrhosis is either of the atrophic or hypertrophic type, is particularly apt to occur in those cases in which there is passive congestion from cardiac failure. On account of such changes in the liver and pancreas atheroma has been called a cause of diabetes.

In conclusion, it may be stated that the subjects of arteriosclerosis should be viewed as possible victims of diabetes, especially if they present any of the usual symptoms of the disease. In the event of failing to discover sugar in the urine 30 grams of glucose may be administered. Failing then to obtain a temporary glycosuria one should feel content that there was little likelihood of being subjected to the humiliation of having some more fortunate observer arrive at a proper diagnosis which in an intermission a single test had failed to reveal.

Dietetic Treatment of Diabetes.

Dr. E. O. Jellinek drew attention to the latest conclusions concerning the circulation of sugar in the blood, according to the recent investigations by Kolisch and others. These investigators have proven that by far the largest part of sugar circulating in the normal, as well as in the diabetic blood, is not pure dextrose, but is a combination with lecithin, forming probably jecorin, and as such is not excreted by the kidneys, sugar appearing in the urine only when either the increase of sugar in the blood is too great to be combined with the available lecithin or if from any reason a decomposition of the jecorin occurs, which results in the liberation of sugar. The work of these investigators would seem to show that diabetes is not a lower assimilative power of the cells, but a pathologic state, in which the protoplasm of the cells separates its own sugar, and the ingestion of food under such pathologic conditions causes an irritation of the cell, in consequence of which sugar is separated, the amount depending upon the intensity of the irritation.

In the grave form of diabetes meat should be interdicted, and the patient placed on an absolute vegetable diet; green vegetables are best adapted for this purpose, and should be boiled with large quantities of water, as they lose part of their sugar through boiling; after this they can be prepared with large quantities of fat. The experience of Kolisch shows that by this form of food carbohydrates can gradually be permitted. In addition, the following is also allowed: Eggs, milk (buttermilk preferred) up to one liter, butter, cheese (cream cheese), fresh fruit, grapes excepted; moderate quantities understood.

If in the milder forms meat be permitted once or twice a week, it is to be boiled, and never more than 200 grams daily be allowed.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Twenty-seventh Annual Meeting, held at Put-in-Bay Island, Ohio, September 12, 13 and 14, 1901.

President Dr. A. H. Cordier, Kansas City, Mo., in the Chair.

(Concluded from page 851.)

Address in Medicine.

Dr. Frank Billings, Chicago, selected for his subject, "What Are the Qualifications Necessary for the Success of the Practice of Medicine?" He said that the qualifications of success, in any walk in life, depended upon the meaning of the word success. Not uncommonly success meant to the majority of mankind the acquisition of wealth. Without a living income life was too full of anxieties to allow one to do good work. The average physician, said the speaker, probably received less compensation for his services than any other member of society, when one considered the time and money spent in preparation, the responsibilities assumed, and the character of the service rendered to the patient. To-day the problems in medicine were so profound that a good preliminary education was necessary to enable the student to pursue the study of medicine rationally and successfully. While a college or university education might not be essential to fully prepare one for the study and comprehension of medicine, still it gave one broad culture, a discipline of mind, which added to the pleasures of life of the practitioner, if it did not bring him material advantage.

Dr. A. M. Phelps, New York, discussed the subject of tubercular disease of the spine, lateral curvature of the spine, and the proper treatment of each.

Congenital Valvular Obstipation.

Dr. Thomas Charles Martin, Cleveland, said this was the result of embryological hyperplasia or overgrowth of the rectal valves, which was characterized by an abnormal depth of the valve, or to such anatomical propinquity of two valves that they overlap and establish under the pressure of the descending force a temporary diaphragm. The symptoms were more or less straining for defecation of solid or semi-solid feces, which developed at an early period and continued.

Varicose Veins and Their Treatment

Dr. J. Lively Johnson, Louisville, Ky., said that varicose veins of the first degree were of little importance, aside from the mental anxiety of the patient, but as the varicosity advanced, the veins assumed a more grave character and were often a source of annoyance to both patient and surgeon. A varicosity might exist in any part of the body. This condition of the veins was found most frequently in certain localities, as the pampiniform plexus and in the veins of the foot, leg and thigh. One of the greatest dangers to the patient suffering from varicose veins was the danger of a sudden rupture, with perhaps fatal loss of blood. Inflammation and thrombosis might frequently occur. The only rational line of treatment to be pursued in the management of varicose veins, in whatever locality, was, as near as possible, to completely remove by extirpation the entire diseased vessels. The surgeon had the choice of a number of operations for the radical cure of varicose veins of the lower extremity. He must be able to adapt the surgical procedure to the case in point.

Use and Limitations of the Elastic Ligature in Intestinal Surgery.

Dr. Theo. A. McGraw, Detroit, said that the elastic ligature was the most advantageous method of making intestinal anastomosis in cases of pyloric stenosis, and of ulcer of the stomach, in chronic partial stenosis of the intestine, and in certain forms of gangrenous hernia. It could rarely be used to advantage where it was necessary to excise any portion of the intestine. Rules were given for its use, and an exhibition of the proper method.

Dr. H. O. Walker, Detroit, reported cases of intestinal resection and approximation by the Connell suture, and contrasted it with other methods of approximation. He spoke highly of this suture, and recommended its use.

Surgical Features of Typhoid Fever and Dysentery.

Dr. Hal C. Wyman, Detroit, held that early operations for perforation in typhoid fever gave the best results. Physicians should anticipate perforation and intestinal hemorrhage in typhoid fever of a severe type by surgical operation, which promised to heal the ulcerated bowel before it perforated or bled. In severe cases of a threatening type, the author said, why not open the cecum near the ileo-cecal valve, establish a fistula through which a tube might be passed cautiously into the ileum and the ulcerated region daily washed with normal salt solution until it healed, and also the colon to rid it of infecting bacteria? When the patient was convalescent, the fistula would close spontaneously.

Some Indications for Gastro-Enterostomy.

Dr. William J. Mayo, Rochester, Minnesota, based this paper on experience derived from 64 operations. In malignant disease gastro-enterostomy was indicated only if symptoms of obstruction were present. The mortality was high, 25 to 30 per cent. The writer lost 4 out of 16 cases. The reason for this mortality lay in the bad condition of the patient. The early cases in good condition needed radical treatment, and the latter operation (pylorectomy, etc.) on this account had an even lower mortality than gastro-enterostomy, which had no such limitations. For open ulcer, gastro-enterostomy was of the greatest benefit if the ulcer was situated near the pylorus, and it usually was. Under such circumstances, the stomach was of normal or increased size, the latter condition being due either to obstruction or pyloric spasm. If the ulcer be distant from the pylorus and the stomach contracted, gastro-enterostomy had less value and the anastomotic opening might close, although the ulcer was usually healed before this took place. The writer had had 13 gastro-enterostomies for open intractable ulcer, with one death. For benign obstruction without regard to origin gastro-enterostomy was the operation of choice, the cure being immediate and lasting. Pyloroplasty enlarged the outlet, but if the stomach was very large and pouched, the degenerated muscle fiber might fail to elevate the food to the pylorus and relief was not always afforded. Gastro-enterostomy drained from the lowest point, and was superior in every way to the plastic operation. In 35 gastro-enterostomies of this class only one died.

Dr. Wm. J. Gillette, Toledo, read a paper in which he reported 100 cases operated on for appendicitis.

Suture of the Abdominal Wall.

Dr. Charles Davison, Chicago, said the main points are, closure of any laparotomy wound by suturing each layer with continuous silkworm gut suture, the ends of which are left out at the angle of the wound, to be removed when healing has occurred. The suture in the strong fascia is tied in position at each end in the fascia with a knot that can be unlocked by traction on the exposed ends when the stitch is to be removed. The advantages of the method are: 1, certainty that all suture or ligament material placed in the wound has been made sterile by boiling in water; 2, accurate layer approximation of tissue; 3, removal of the buried sutures when healing is complete; 4, capillary drainage from each layer; 5, safety of intestines from injury during the application of the sutures; 6, rapidity of application; 7, minimum line of irritation on the peritoneal surface and consequent adhesion to viscera; 8, slight scar in the skin, there being no perforation of the skin by sutures; 9, all of the advantages of a permanent buried suture without the danger of future irritation and extrusion; 10, the advantages of an absorbable suture without the danger of sepsis from the suture and without producing a nidus for septic germs from the blood current during absorption.

Dr. Truman W. Brophy, Chicago, demonstrated some cases of surgery of the palate by the aid of stereopticon views.

Dr. M. L. Heidingsfeld, Cincinnati, discussed some causes of ignored syphilis and their remedies, and gave clinical examples.

Hematology.

Dr. L. H. Warner, New York City, spoke of the imperfect methods of obtaining blood from patients for microscopic examination, and said that the subsequent incorrect methods of fixing and staining specimens had frequently caused errors, the results being of no value as an aid to diagnosis. The incorrect understanding as to the physiologic action of the electro-saline halogen derivatives (iodin, bromin, chlorin), especially as to the amount resorbed (chemical uranalysis), had caused leucocytosis to be wrongfully attributed to other causes. The blood in infectious diseases, if properly obtained and examined in the hot stage, showed certain histologic changes in the red cells, also certain staining affinities which enabled the hematologist to arrive at an early diagnosis in cases of syphilis, carcinoma, etc.

Hay Fever.

Dr. A. D. Murphy, Cincinnati, said three conditions were necessary to produce the complaint, namely, depleted nerve centers abnormally sensitive to uric acid; abnormal condition of the nasal cavities, and atmospheric and climatic conditions.

Consequently, to effect a cure it was necessary to eliminate the uric acid, restore the depleted nerve cells to their normal condition, and relieve the effects. Hot baths and exercise and the careful selection of food were all of importance. As regards medication, he relied principally on a combination of arsenic and solution of gold, supplementing it with local applications of the suprarenal extract, or its active principle, adrenalin.

Scientific Aids to Diagnosis.

DR. HENRY D. HOLTON, Brattleboro, Vt., passed over percussion and ausculation as means of examining the heart and lungs, and simply mentioning the importance of making chemical and microscopic examinations of the urine in cases where the symptoms indicated an abnormal condition of the kidneys, and also those in which the symptoms were vague and uncertain. He proceeded to refer at length to an aid that had not found general favor with the profession, to wit, the use of the ophthalmoscope in many affections of the brain and spinal cord, in which he contended it had been proved to be of great value. He also spoke of the help to be derived from the examination of the blood.

Dentist's Neck.

DR. ALBERT E. STERNE, Indianapolis, portrayed a hitherto undescribed neurosis to which he gave the name of "Dentist's Neck." When it first attracted his attention, he thought the affection was unique, but he had since come to the conclusion that it was by no means rare, and that it sometimes attained the dignity of seriousness to the afflicted individual. As to the pathology of the affection, he admitted that he had to rely largely on conjecture. He believed that it was in many respects analogous to other occupation neuroses, not only in its etiology of regionary overstrain, but also in its cerebral functional character. In all these complaints he considered the peripheral manifestations as secondary to the localized braincell fatigue.

Necessity of and Indications for the Bed-Treatment of the Insane.

DR. F. P. NORBURY, Jacksonville, Ill., said insanity, in its incipient stage, responded readily to treatment, hence the importance of early recognition and appropriate treatment.

DR. HAROLD N. MOYER, Chicago, discussed the subject of "Puerperal Insanity."

DR. JOKICHI TAKAMINE contributed an account of his discovery of the active principle of the suprarenal gland, to which the name of adrenalin has been given. He also explained the mode of preparing the drug.

DR. B. T. WHITMORE, New York, in a paper on "Indian Contributions to Therapeutics," showed that the modern so-called Indian remedies have no connection with any system of medication practiced by the aboriginal Americans.

The Dyspeptic's Diet.

DR. GEORGE D. KAHLO, Indianapolis, contended that diet was a more important therapeutic agent than medicine. Perfect nutrition was of primal import, and could only be maintained by a mixed diet, in which there must be a proper proportioning of the elementary food substances.

Personal Element of Error in Therapeutics.

DR. GEORGE F. BUTLER, Alma, Mich., said the personal elements of error are accepted in all the exact sciences, not excluding astronomy. In medicine this element does not receive allowance, except to some slight degree in histology, pathology and neurology. It is practically neglected in therapeutics. This is due to the crude empirical methods employed, and the lack of judicial training. The personal element leads to the eulogy of worthless remedies and the ignoring of unusual effects of beneficial ones. The early but ignored recognition of the uselessness of sarsaparilla by Weir Mitchell illustrates this. Only the recognition of this personal element can render therapeutics scientific. The elements involved are proper diagnosis, not merely of the disease, but of its type, recognition of individual peculiarities of the patient, recognition of the proper preparation of the remedy, recognition of its untoward effects, and, finally, recognition of the fact that pathologic states indicate a new force introduced into the organism which disturbs its balance.

The Acquirement of Nervous Health.

DR. F. SAVARY PEARCE, Philadelphia, discussed the pathogenesis of nervous and mental diseases, and from the standpoint of salient signs and symptoms of the so-called "nervous breakdown" in the earlier periods of development, detailed medical guidance in prophylaxis. Insistence is made upon the urgent necessity of more serious recognition by the profession of the points elucidated in the paper, if the wear and tear of modern exacting American life is to be forestalled in its baneful influence upon the acquired nervous temperament of many, and of business men in particular, in the temperate zone of the United States. Cases cited and good results given.

A short symposium on tuberculosis was introduced by Dr. Charles F. McGahan, Aiken, S. C., who dealt with the treatment of the disease in the patients' homes. He was followed by Dr. Howard, Champaign, Ill., who reported favorably on the treatment of tuberculosis with formaldehyde and its salts. Dr. William A. Dickey, Toledo, Ohio, who read the third paper in the series, spoke on the attitude of the profession toward the public and the individual suffering from tuberculosis.

The evil effects of alcohol were discussed in papers by Dr. T. D. Crothers, Hartford, Conn., and Dr. T. B. Greenley, Meadow Lawn, Ky. Dr. Charles H. Shepard, Brooklyn, in a contribution on "Auto-Intoxication and Its Treatment," entered a plea for the greater use of Turkish baths. Dr. Ernest Gallant, of New York, narrated his observations on a tripartition in the study of the female pelvis. Dr. N. Stone Scott, of Cleveland, showed stereopticon slides from original photographs, illustrating the anatomy, embryology, histology, comparative anatomy and pathology of the appendix.

Dr. Reginald A. Sayre, of New York, delivered the "Address on Surgery." He reviewed the status of surgery during the past and noted the changes that have taken place in men, methods and modes of thought, and speculated on the position which surgery would attain during the next one hundred years.

After election of officers, and the passing of resolutions on the death of President McKinley (see last week's issue, p. 792) the Association adjourned to meet in Kansas City, Mo., in 1902.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

The Treatment of Whitlows.

The following treatment has been recommended for the treatment of felon: The felon should first be incised deeply and aseptic gauze saturated in the following solution introduced into the open wound as deeply as possible, over which a compress of a solution of plumbi acetas is applied:

℞.	Iodi (pure)	ʒiiss	10
	Tinct. iodi		
	Tinct. rhatany āā	ʒi	4
	Pot. iodidi	ʒss	2
	Glycerini	℥i	32

M. Sig.: For external use as indicated above.

It is stated that this treatment will cause suppuration to cease immediately and healing of the wound in a very few days.

Treatment of Purulent Pleurisy (Empyema).

It is recommended by Capitan, in *La Méd. Mod.*, that all fluid possible be removed by aspiration; if the cavity refills, remove the fluid again and inject a few drops of camphor and beta-naphthol, equal parts, or some peroxid of hydrogen. If this does not stop pus formation an opening should be made under *cocain* anesthesia and drainage established. He thinks the removal of a rib to be unnecessary. To avoid cardiac and respiratory disturbances resulting from the removal of the pressure in the cavity, he recommends the following in the form of an injection.

℞.	Cocainæ hydrochloratis	gr. iss		09
	Morphinæ hydrochloratis	gr. ¾		05
	Sparteinæ sulphatis	gr. iii		18
	Atropinæ sulphatis	gr. 1/3		02
	Aq. destil.	ʒiiss	10	

M. Sig.: Inject fifteen to thirty drops hypodermically as heart stimulant and to allay the cough.

As a substitute the following may be employed as soon as the fluid is removed:

℞.	Sparteinæ sulphatis	gr. ¾		05
	Caffeinæ citratæ	gr. iii		18
	Sodii benzoatis	gr. iii		18
	Aq. destil.	m. xv	1	

M. Sig.: Use the entire amount hypodermically.

Treatment of Varicose Ulcer.

A powder composed of the following is of great service in treatment of ulcers as result of broken-down varicose veins:

℞.	Iodol.	ʒiv	16
	Zinci oxidi	ʒii	8

M. Sig.: Dust freely upon the affected part and apply the dressing, which should be changed every other day.

The following is also recommended under the same circumstances:

℞.	Ichthyol	ʒi	4
	Gelatini	ʒii	8
	Zinci oxidi	ʒi	4
	Glycerini	ʒiii	12
	Aq. destil.	℥ss	16

M. Sig.: Heat the above and paint on the ulcer, first cleansing the ulcer with an antiseptic solution and drying.

Treatment of Rheumatic Synovitis.

℞.	Sodii salicylatis	ʒiv	16
	Sodii iodidi	ʒiv	16
	Aq. menth. pip.	℥vi	192

M. Sig.: Two teaspoonfuls in water four times daily.

The following applied locally will be absorbed:

℞.	Methyl salicylatis	ʒiv	16
	Lani	℥ii	64

M. Sig.: Apply to the affected joint on lint, night and morning.

Proper Method of Bandaging Diseased Breasts.

Harris, in the *Annals of Gyn. and Ped.*, makes the statement that inflammation of the nipple and breast should be regarded as a progressive rather than a self-limited disease, arising in most instances from septic infection of the nipple. Bandaging is regarded by him as advisable after mastitis, stillbirth, and whenever weaning is necessary on account of mammary disorders. It is recommended by him that the bandage be used in cases of infection of both breasts, and where nursing must be entirely stopped. In applying his bandage, when only one breast is involved, he uses a roller bandage two and a half or three inches wide and nine or ten yards in length. Both breasts are protected by absorbent cotton. Beginning beneath the breast affected the bandage is passed twice around the body, then under the affected breast and over the opposite shoulder, then around the body again and underneath the breast and over the same shoulder. It is then brought again under the affected breast and passed around the chest above the sound breast and immediately over the affected breast and above the sound breast and continued until the affected breast is entirely covered, and finally over the shoulder again. It must then be kept in place with safety pins in the back, sides, and front. An opening may be made so that the infant may have access to the sound breast.

Bacon, of Chicago, recommends for supporting the breast and putting it at rest a bandage six or seven inches wide. In applying this bandage the breast must be raised, not compressed; with the patient lying on her back, the bandage under her, the nurse takes hold of one end of the bandage and draws the breast up to the middle of the chest, holding it there with the bandage. The other breast is raised and held in the same way, after which the bandage is fastened by several safety pins, the lower border being drawn more tightly than the upper. Strips of bandage may extend over the shoulders to hold this bandage in place. His method of applying the double Y bandage is more efficient than the one just described. It is made of strong cotton cloth, consisting of a back piece four or five inches wide and from fourteen to twenty inches long. To each end are sewed two diverging strips, each four or five inches wide and thirteen inches long. The lower limbs of the Y's which pass under the breast are fastened together with safety pins; in the same manner the upper and lower limbs of the Y's are fastened in front with safety pins to support the inside of the breasts. With this bandage the nipple of the sound side may be left free for the infant.

Treatment of Pruritus Vulvae.

L. Siebourg, in *Centralblatt f. Gyn.*, states that the removal of causative factors is imperative. An exact uranalysis should be made. The diet should be regulated. Alcohol and highly seasoned foods should be interdicted. Rubbing or scratching of the vulva should be prohibited. The diseased parts should be washed with water and pure soap after each urination. The following should be applied to give relief from the itching:

℞.	Cocainæ	gr. xxx	2	
	Orthoformi	gr. xxiv	1	50
	Menthol	gr. viiss		50
	Acidi carbol.	gr. xv	1	
	Vaselini	ʒv	20	

M. Sig.: Apply locally to relieve the itching.

Generalized Pruritus.

J. F. Schamberg, in *Ther. Gazette*, recommends the following to be taken internally in cases of chronic pruritus over different parts of the body:

℞.	Acidi carbol.	ʒss-ʒi	2-4
	Glycerini	ʒi-ʒii	4-8
	Vini xerici, q. s. ad	℥iii	96

M. Sig.: One teaspoonful after each meal.

Dr. Schamberg states that he employed the above treatment in several cases of general itching which extended over several months, with improvement in all cases and cure in some of them.

Treatment of Locomotor Ataxia.

Dr. S. Leduc, in *Gazette Médicale de Nantes*, stating that in tabes dorsalis, dependent upon a history of syphilis, has injected into the gluteal region of the patient the following:

℞.	Hydrarg. chloridi, corros.			
	Sodii chloridi (recrystall.) āā	gr. iii		20
	Aq. destil.	ʒv	20	

M. Sig.: Inject about thirty drops daily into the thigh.

Sodium Formate in Pneumonia.

Polenov, as noted in *La Semaine Med.*, recommends the following in modifying the fever and shortening somewhat the duration of the illness:

℞.	Pulv. adonis vernalis (folia)	gr. xxx	2
	Aq. bulientis	℥vi	182

Ft. infusio. Filter and add:

Sodii formatis	gr. xxx-ʒi	2-4

M. Sig.: One tablespoonful every two hours, day and night.

Sodium formate is a white deliquescent crystalline salt, soluble in water or glycerin.

Pityriasis of Face and Eyebrows.

The following is recommended in treatment of this affection as noted by *New York Med. Jour.*:

℞.	Lithii benzoatis	gr. xv	1
	Tinct. benzoini	ʒss	2
	Glycerini	ʒss	2
	Tinct. eucalypti	ʒi	4
	Aq. rosæ	℥i	32

M. Ft. lotio. Sig.: Apply locally night and morning.

Medicolegal.

Skull and Photograph Admissible in Evidence.—The Supreme Court of Nebraska holds, in Savary vs. State, that when physicians called as experts in a criminal trial for murder, in testifying to the manner and cause of death, refer to and use the skull of the deceased and a photograph thereof in explanation and as a part of their testimony, it is not erroneous to admit the exhibits as evidence in the case.

Proof on Insanity to a "Reasonable Certainty."—The Supreme Court of Georgia says, in Minder vs. State, that in order to sustain the independent defense of insanity at the time of the commission of an alleged criminal act, it is incumbent upon the accused to prove that he was insane at that time; and it holds that an instruction that he must prove this to a "reasonable certainty" is not erroneous, when the jury are distinctly informed that a preponderance of the testimony is all that is requisite to establish such reasonable certainty.

Ground for Annulment of Marriage to a Syphilitic.—While the Court of Chancery of New Jersey says, in the case of Crane vs. Crane, that to annul a marriage for a fraudulent representation inducing the contract, it must be shown that the fraud affected an essential of the marital relation, it holds that an explicit statement by a man about to be married that he was not afflicted by the loathsome disease called "syphilis," made when it was his duty to state the truth, and knowingly false, is such a fraudulent representation as affects an essential of the marital relation, and warrants an annulment of the marriage for fraudulent representation.

Court Terminates Lengthy Malpractice Litigation.—In the late appeal from a judgment for the plaintiff in the malpractice case of Margaret Leach Barker vs. Lane, the Supreme Court of Rhode Island says that the verdict was clearly against the evidence. Whether the defendant used proper professional skill and diligence in treating the plaintiff's arm was a question which must be determined by the testimony of experts in medicine and surgery. A number of these were called, some by the plaintiff and some by the defendant, and they all substantially agreed that the method of treatment adopted by the defendant was professional and proper. Taking their testimony in its strongest light in favor of the plaintiff, it only showed an error of judgment on his part in treating the arm; and such an error, merely, the court holds, is not enough to sustain an action of this sort. Continuing, the court says that the treatment of which the plaintiff complained occurred in 1892, but no action therefor was brought until in 1895. The case has now been tried five times, with varying results; and in 1897 a verdict for the plaintiff was set aside by the court for the same reason that the present verdict is set aside. The declaration has been repeatedly amended, and at least four of the original witnesses are now dead. Then the court adds that it is of the opinion that the plaintiff, after the lapse of nearly nine years, must be presumed to have presented all the evidence which is now available in her behalf, and that the interests of justice will not be subserved by a further prolongation of this litigation. "It concerns the state that there be an end of lawsuits." Wherefore, the Supreme Court remands the case with direction to enter judgment for the defendant.

Communications to Volunteer Physician Privileged.—After a boy who had been injured by a street car was taken to a drug store, one of the surgeons employed by the street car company went in to see him, and volunteered his services to stop the flow of blood until the ambulance arrived. He subsequently saw the boy at the hospital 10 days after the accident. The boy was then in bed in the ward, and the doctor asked him to tell the details of his accident, to which the boy made reply. Now, he certainly, while thus attending to the boy to stop the flow of blood, the first appellate division of the Supreme Court of New York holds, case of Griffiths vs. Metropolitan Street Railway Company, occupied to the boy the relation of physician, and when he subsequently went into the hospital, after the amputation of the boy's leg, and asked him questions as to the accident, the boy was justified in treating him as a physician who had attended him. Continuing, the court says that his going to the hospital, having no previous acquaintance with the boy, no interest in the case except in his professional capacity, and attempting to obtain from him declarations as to the accident, was unauthorized and impertinent. Declarations made by the person thus severely injured, made to a physician under such circumstances, would certainly be privileged. Except as a physician, he had no business in the hospital. He did not inform the boy that he came as a representative of the street railway company, and for the purpose of extracting from him an admission which would tend to relieve the company from liability. Under such circumstances, the boy was quite justified in considering a person who thus addressed him as a physician, and in answering his questions freely and frankly, without considering that his answers would be used against him as admissions. Wherefore, the court holds that the testimony of the physician was correctly excluded, on the trial of the action against the company.

Risks Taken by Patient in Charitable Hospital.—The United States Circuit Court of Appeals, First Circuit, has affirmed, in the case of Powers vs. the Massachusetts Homeopathic Hospital, the decision of the Circuit Court reported on page 899 of The Journal of Oct. 6, 1900. In other words, it holds that a patient admitted to a hospital maintained for charity can not recover judgment against the hospital for injuries caused by the negligence of a nurse employed therein. It considers it immaterial, too, that the patient in this case was what is sometimes called a "paying patient." That the ministrations of a hospital organized as a charitable corporation, that is, exclusively for charity, should be confined exclusively to the indigent, it says, is not usual or desirable. Those of moderate means from necessity, and not a few rich people from choice, resort to great charitable hospitals for treatment, especially in surgical cases. Throughout the world this is the custom in these institutions, whether they are maintained by individual, religious, or municipal charity. From patients who are not indigent, a payment is commonly permitted or required. Commonly, this payment does not make full pecuniary compensation for the services rendered. Those who make a considerable payment not infrequently receive in some respects a more expensive service than do those who make a small payment or none at all; but the payment required is usually calculated upon the patient's ability to pay, rather than upon the whole cost of the treatment he receives. That was plainly the rule of the hospital in this case, and the court is of the opinion that a paying patient in it, as well as a non-paying patient, seeks and receives the services of a public charity. That such a hospital in its treatment of a rich patient should be held to a greater degree of care than in its treatment of a pauper is not to be tolerated. Certain luxuries may be given the former which the latter does not get, and this for various reasons; but the degree of protection from unskilled and careless nurses must be the same in both cases. Again, the court says, it would be absurd to make the hospital's liability for an accident, such as the burning of a patient with a hot water bag, depend upon the payment of that insignificant proportion of the cost of the service rendered which in some cases may properly be required from a poor man or woman. So the court is of the opinion that this case stood as if the patient had been admitted without any payment whatsoever, instead of with an agreed one of $14 a week. Then it holds that one who accepts the benefit either of a public or of a private charity enters into a relation which exempts his benefactor from liability for the negligence of his servants in administrating the charity; at any rate, if the benefactor has used due care in selecting those servants. To paraphrase the illustration used by the Circuit Court, it would be intolerable, it says, that a good Samaritan, who takes to his home a wounded stranger for surgical care, should be held personally liable for the negligence of his servant in caring for that stranger. Were the heart and means of that Samaritan so large that he was able, not only to provide for one wounded man, but to establish a hospital for the care of a thousand, it would be no less intolerable that he should be held personally liable for the negligence of his servant in caring for any one of those thousand wounded men. And the court can not perceive that the position of the hospital in this case differed from the case supposed. The persons whose money has established it are good Samaritans. The purity of their aims may not justify their torts or wrongful acts, but, if a suffering man avails himself of their charity, he takes the risks of malpractice, if their charitable agents have been carefully selected.

AMERICAN.

1. **Floating Kidney.**—The operation here described by Beyea is as follows: A longitudinal incision is made in the lumbar region parallel with and about 4 fingers' breadth from the spinous process of the vertebra, thus close to the anterior border of the spine muscles. It begins just below the last rib and extends downward for a distance of 3½ inches. The skin and fat are divided down to the fascia, the fascia incised, the muscles separated in the direction of their fibers, cutting again through the lumbar fascia and separating the quadratus lumborum muscle. The perirenal fat is exposed and is likewise excised, opening the space of Gerrotta. Then by rolling the patient downward on the Edebohls inflated bag, assisted often by traction of the perirenal fascia and the pressure of the assistant's hand opposite to the incision on the anterior abdominal wall, the kidney is delivered out of the wound. The surgeon then selects a position at the hilum of the kidney in the perirenal fascia which is free from blood vessels, and about one centimeter from the ureter and renal vessels, which he perforated with the blunt end of a dissecting forceps. Then an ordinary rubber drainage tube, previously sterilized and of sufficient length to surround the kidney and protrude for some distance out of the wound when the kidney is replaced, is introduced through this opening made with the forceps and clamped. Similarly, a second tube is introduced below the ureter and vessels and surrounding the kidney. The drainage tubes being surrounded by and passing through an opening in the perirenal fascia at the hilum, are prevented from changing their position and slipping over the convex end of the kidney, or in any way from interfering with the ureter or vessels. The kidney is then replaced, the drainage tubes extending through the incision. The muscle incision is sutured, leaving a small opening for the tubes, with continuous catgut suture, often by two layers of such suturing. The skin wound is closed by an intracutaneous suture, again leaving the same opening. An oblong portion of gauze is now placed over the wound, and over this, with gentle traction, are tied the elastic drainage tubes. The tubes, being elastic and tied with little tension, the kidney tissue can not be restricted or its circulation interfered with. The kidney is secured a little below the normal, and in the most favorable position. The usual dressing and binder are placed over the wound. The first dressing is made at the end of ten days, the silk intracutaneous suture being removed at this time. The tubes, which easily slip out, are removed after three weeks. The wound left by them quickly heals, being completely closed within three or four days. The operation was first planned and practiced by C. B. Penrose and has been performed in eight cases. All the patients have been carefully examined and the kidney found fixed in these, and in all but one the symptoms were entirely relieved. In this one case the patient still suffers from gastroptosis, which it is hoped will be relieved by further operation. After two and one-half years Beyer is thoroughly convinced that the operation can have no deleterious influence and is associated with no danger, and, therefore, in the future will be the operation of election in nephropexy. The rubber tubing, if aseptic, acts simply as a foreign body, causing very mild irritation and never producing excessive adhesions to injure the kidney structure, but just enough to hold the kidney in a fixed position, and the tube tracks heal with the smallest cicatrix.

2. **Thoracic Duct.**—In the former portion of this article appearing in the last number of *American Medicine*, Allen and Briggs described some theoretical and practical questions in regard to thoracic duct injuries and report a number of cases. In this article they give a more detailed study of these cases and offer the following as suggestions to which they have been led: 1. The increasing frequency of extensive dissections in the neck makes it desirable to consider means of avoiding injury to the thoracic duct. 2. It is desirable that if wounds of the thoracic duct or its branches occur, they should be recognized at the time of operation. The ingestion of 4 to 6 ounces of cream 3 hours before operation might be especially desirable in secondary operations undertaken for the purpose of locating the point of injury. The desirability of such a procedure may be further studied by observations made upon animals. 3. That suture of the duct with fine silk or catgut be accomplished where possible; that all small discharging lymph radicles be ligated; that the ligating and clamping of lymphatic vessels of considerable size be avoided, unless the integrity of the thoracic duct itself has been demonstrated; that where suture of the duct or large radicles is impossible, gauze packing, firmly and accurately applied, be used; that the head and neck be kept at rest, the use of morphin to a considerable degree being recommended if necessary. 4. That until repair of the duct is thought to be complete, nutrition should be sustained on albuminous material, with possibly a small amount of carbohydrates, but with an absolute exclusion of fats.

4. **The Therapeutic Value of Alcohol.**—Solomon's article considers alcohol as a medicine, not as a beverage, which he says does not concern us in this discussion. The healthy man does not need alcohol any more than he needs any other stimulant or narcotic and Lawson Tait's statement that a moderate use of alcohol is a necessity in modern times is too bold and in bad taste from a medical man, and dangerous since it comes from so high an authority. He thinks it should be given tentatively, never as a routine medicine. Alcohol is of value as a stimulant, as a conservator of vital power, for supporting the vital powers of life in sudden depression and supplying heat to the system where it is needed, in chronic suppuration and wasting diseases, and locally in many affections.

5. **The Lane Lectures.**—In the second lecture Morris gives an interesting account of the discovery of itch mite, and points out, however, that it had been recognized by early writers, even by Rabelais, though its discovery for practical purposes dates from the early part of the 19th century. While it is a trivial affection of the present day, cured by one or two treatments, it has been a scourge in the past when it was not understood and he gives an account of Napoleon's experience and calls attention to the fallacy of the fear of driving in an eruption which is not completely exploded at the present day. As regards lice, he remarks that these seem to have their preference; for instance, the experiment of Crocker of a half a dozen students around a table on the middle of which was placed a hungry pediculus; in whatever direction the insect was headed, it always promptly made for one particular student. The lowered condition of the system favors their development and the most exquisite dandy who goes to war, where the toilet has to be more or less neglected, will find himself a victim. He remarks on the progress of personal cleanliness in modern times, calling attention to Lady Mary Wortley Montagu, who was a beauty as well as a wit, and had lived in the East where the bath was a religious institution. Yet it is told that, on someone venturing to hint that her hands were not quite up to the not very high standard of cleanliness required by society in those days, exclaimed: "Do you call that dirty? What would you say if you saw my feet?" At the present time, he thinks it is possible we carry the cult of bath a little too far. The flesh brush may be overused and an irritable condition of the skin produced, but he does not recommend the maxim attributed to a German professor that "dirt is a natural protection to the skin" as a precept of cutaneous hygiene.

6. **Carcinoma of the Esophagus.**—Cumston's article, which was commenced in an earlier number, discusses the subject of esophageal carcinoma of which he recognizes five principal types: 1. The classical simple type without complication, showing itself largely in difficulty in swallowing. 2. The tracheo-bronchial type, producing compression, dyspnea, ulceration, etc. 3. The laryngeal, where it extends to the mucous membrane, muscle and cartilage of the larynx producing similar symptoms. 4. The pulmonary type of disease extending to the lungs and involving the pneumogastric. The cardiovascular form involving the heart and producing dilatation of the aorta and finally perforation of the large vessels. It may also extend to the pericardium, and the heart itself giving rise to various cardiac symptoms, those of pericarditis and endocarditis. He mentions briefly two symptoms of esophageal carcinoma, viz., the laryngotracheal pulsations, first described by Castellino, and unequal pupils, observed by Hitzig. The

clinical value of this latter symptom is small as it may occur in other conditions. The methods of diagnosis are noted—auscultation, catheterism of the esophagus, esophagoscopy, and the use of the Roentgen rays. In conclusion, he describes at length the operation of gastrostomy.

9. **Animal Heat.**—The conclusions derived from Levin's study of the heat economy and of fever are as follows: Heat economy seems to resemble general metabolism inasmuch as it is a result of the joint work of many organs of the body; and fever, the most important pathological state of heat, is in most instances a special kind of intoxication by some substances not as yet well defined. Further work will have to show the precise nature of these substances, and also decide the question whether there is some central apparatus conducting all the complicated works of the heat economy, and what the nature and office of such an apparatus are, if it does exist. He is inclined to believe that later researches seem to show that fever is not always deleterious; it is sometimes beneficial to the economy, though the question is by no means settled, but the truth must certainly lie somewhere between the two extremes. An ordinary febrile temperature does no harm as a rule, often probably does some good. The doctrine, therefore, that every rise of temperature must be fought against and reduced by all means is wrong, since none of the metabolic and other changes accompanying fever is in any way influenced by antipyretics.

11. **Gunshot Wounds.**—The late results of gunshot wounds are elaborated in some thirteen cases of injury from the Mauser bullet examined by Leale, and who finds that they are far less severe from modern projectiles than from those formerly used, and that the change to the use of the small bore rifle has proven to be a great blessing in modern warfare.

12. **Postero-Ocular Hot Water Injections.**—Allen suggests that in case of neuroretinitis involving the retina and choroid, this might be treated by hot-water injections applied to the posterior portion of the eyeball and optic nerve and by adding sodium chlorate to the water sufficient to raise its specific gravity higher than that of the blood, we have all the conditions for osmosis. He has experimented on rabbits to see whether pathologic changes follow the operation and after performing his operation says it caused no serious traumatism, that no change has taken place in the eye or any of the media in these animals.

13. **Copper Sulphate.**—The use of copper sulphate in diseases of the conjunctiva and cornea is condemned by Williams, who concludes as follows: 1. Copper sulphate in ocular affections is maleficent in its effects. 2. Any good effect following the application of the solid copper sulphate in any disease of the eye may be obtained with the use of safer and practically painless means. 3. Trachoma is most successfully treated with weak solutions of silver nitrate, together with frequent irrigation with a weak bichlorid solution in normal salt. 4. No application to an inflamed conjunctiva which produces a lasting pain should be countenanced. 5. Expression is not absolutely essential, yet much hastens the cure of trachoma. 6. A mydriatic should be used in every disease of the eye involving corneal lesions. 7. Copper has ruined more eyes than it has ever benefited.

14. **Hypochondriasis.**—The evil effect of operations performed on account of the delusion of hypochondriasis to aid the mental condition are pointed out by Pick and he gives several instances illustrating his views. In the first part of the past century such operations were recommended and common, and he thinks that these methods are not as yet entirely discarded. His paper is, therefore, a warning against their repetition.

15. **Glaucoma.**—The method of treatment of the unaffected or slightly affected eye in glaucoma is discussed by de Schweinitz, who offers the following conclusions, as suggested by a consideration of the subject: 1. In cases of acute glaucoma the apparently unaffected eye should be operated upon as soon as the anterior chamber is restored in the opposite eye; that is to say, as soon as the wound is closed, provided the history of the case or an examination of the eye furnishes indications already described that it is likely to suffer a glaucomatous attack like its fellow, especially if the patient is so situated that he or she will pass from observation and from the resources of expert examination. 2. In cases of chronic congestive glaucoma the same line of advice applies, and the operation is to be urged if clear information can be obtained that the apparently unaffected eye has suffered attacks of nebulous or iridescent vision, associated with increased intraocular tension. 3. In cases of chronic simple glaucoma, if any periods, however temporary, of increased intraocular tension can be demonstrated according to the methods already suggested, operation should be performed even if central and peripheral vision are perfectly intact. Even when these are normal, careful perimetric examination may reveal a scotoma of the character already described; if so, operation should not be postponed. 4. In cases of absolute glaucoma the same line of advice expressed under Nos. 1 and 2 is applicable.

16. **Color-Blindness.**—William and Archibald Thomson describe the model of a lantern devised by them for the detection of color-blindness, which they think meets certain needs not entirely met by the ordinary tests, especially by the too great reliance on the wool test, the unreliability of which has been pointed out by Edridge-Green and others. They give reports of several cases which show the defects from dependence upon this method alone. They are now of the opinion that with the use of colored lights, a non-professional examiner can do good work, and the use of the lanterns here described reveals color-blindness without doubt, and with prominence and certainty.

17. **Light Treatment.**—The treatment of pulmonary tuberculosis by light is discussed in this second paper by Hopkins, who has used a 50-ampere electric lamp with a 20-inch condensing lens, and has had this arranged with an adjuster so that at a distance of 15 feet the light could be concentrated on a surface an inch in diameter if it should be desired. In using this lamp, a screen made of strips of blue glass is interposed between the patient to cut off some of the heat rays. The chest of the patient is bared and the light concentrated to a circle from fifteen to twenty inches in diameter, according to the tolerance of the patient. The exposures vary from half an hour to an hour daily. The first effect of the light observed is the diminution of cough and the temperature within forty-eight hours. In most cases the temperature is down to nearly normal within the first week of treatment. The effect is judged largely by the gain in weight. In every case the amount of expectoration is perceptibly diminished and the number of bacteria is reduced in the first week of treatment. The effect on the appetite is always marked from the very first. He has treated eleven cases in all and his success warrants its continuance. He cautions in regard to exposure to cold without careful protection for some hours after taking the treatment, for fear of overtaxing the kidneys, and advises also careful examination of the urine in every case where the treatment is being given.

18. **Tuberculosis.**—Heron is a strong advocate of tuberculin in tuberculosis and reports his experience. He thinks it is as safe as any other potent drug. He, however, reports the case of a girl in whom it seemed to act very badly, though only a very small quantity was given. There is a question as to the case being tuberculosis, which he thinks improbable as there was no reaction, and he believes that the death was not due to tuberculin.

19. **Gynecology by the General Practitioner.**—The history of gynecology in this country is first given by Reynolds in an article appearing in the previous number of the *Boston Journal*, in which he calls attention to the fact that gynecology is not exclusively a surgical subject and to the necessity of correct diagnosis. The physician should look after the physical state of the pelvic organs, investigate the diathesis, uric acid, etc., and pay careful attention to the symptomatology. In this number he calls attention to the psychologic side of the evils due to imperfect methods in investigating the cases, false modesty, and to proper instruction in regard to the dangers of gonorrhea and syphilis in men as an element of pre-

ventive medicine. The evils of corsets for young girls are also mentioned and the necessity of repairing lacerations and other injuries incident to parturition before the climacteric period. The importance of looking after cancerous and irritative symptoms, ovarian and renal troubles in women, especially cystitis, and physical examination of the urinary organs which is too often neglected are emphasized.

20. **Movable Kidneys.**—Watson announces that the object of his paper is first to protest against the view that movable kidney is originally a harmless condition, to determine its essential etiologic factors and to record certain postmortem observations that suggest an explanation of certain severe symptoms. The frequent presence of movable kidney in neurasthenia would indicate that it had a connection with that condition. There are other more serious consequences; among these are: 1. Hydro- and pyonephrosis. 2. Abnormal fixation of the kidney. 3. In rare instances gangrene of the organ caused by occlusion of its blood vessels by twisting. As regards hydro- and pyonephrosis he quotes Gigon, Albarran, Tuffier and others, and reports cases of the second difficulty, abnormal fixation of a previously movable kidney. The etiologic factors are discussed at length and the author considers that movable kidney results from a defect in the perirenal structures, fascia, etc., described by Glantenay and Gossett, with the possible influence of the shape and size of the paravertebral fossa in which the kidneys lie beneath the diaphragm. He reports cases in conclusion where the fibrous tissues from the peritoneum had restricted the movements of the kidney, causing a partial twist of the ureter and accounting for the occasional acute attacks of pain.

21. **Visceral Ptosis.**—The special influence of corsets in the etiology of visceral ptosis are treated of in this preliminary communication of Vietor's, and she recapitulates the essential points of the helpful corset for visceral support: A straight front, made of several sections running from below obliquely upward and backward; hip gores; back gores; fit the abdomen first, and from below upward; then fit the chest; leave the waist as it falls into place. The patients should be specially warned that it is not enough to have a straight front, but that there must be room in the back for an oblique pelvis. She lays stress on leaving the middle lacing absolutely alone, merely tying the ends for tidiness.

22. **The Home Sanatorium Treatment of Tuberculosis.**—Bowditch favors the erection of sanatoriums for the treatment and cure of consumption wherever the disease prevails. and doubts if we are yet in a position to judge fairly as to the relative results obtained by sanatoriums in different climates. He thinks, however, at present, perhaps better results can in all probability be obtained from this form of treatment in the Western rather than the Eastern section of the country.

23. **Eosinophiles.**—Williams has studied the eosinophiles in pus and has found them in every specimen examined. He believes that they are not to be regarded as a specific cell, but purely a pathologic one resulting from a natural, alkaline decomposition of the body of a common leucocyte. The eosinophile is a necrotic cell.

26. **Dilatation of the Cervix.**—The different methods of dilatation and their indications are noticed by Garrigues. He mentions painting the cervical portion with cocain, chloral hydrate, antipyrin, etc., the tamponade and manual dilatation by Harris' method of introducing the index finger and massaging with it and that of Bonnaire; either of which are preferable to the old pressure with the cone-shaped hand, which is likely to cause tears, and by hard dilating instruments, which are even more objectionable. Bags filled with fluid are of indisputable value, but are not without their drawbacks; they are apt to provoke too rapid and violent labor pains, favor prolapse of the cord and may push the presenting part away from the brim. Cervical incisions are also mentioned, but are not to be compared with comparatively bloodless dilatation by the hands or instrument.

30. **Otitis Media Mucosa.**—Alderton calls attention to a generally unrecognized ear disease which seems to occur with relatively more frequency in adults and usually following a severe cold, producing first, sometimes earache yielding quickly to the ordinary remedies, but more often tenderness around the auricle, with hardness of hearing, tinnitus, mental embarrassment and distress and sometimes vertiginous attacks. The aurist, who is generally consulted early, finds but little congestion and no swelling in the external ear. The tympanic membrane is seemingly in about its usual position, possible pushed out a little more than normal, the luster is gone, the surface has a dull gray, leaden appearance. Surrounding this dull gray field is a ring of congestion, and coursing across the field are a number of separate capillary twigs. There is no fluid line discernible, nor can the pressure of fluid be made out by any difference in the appearance of the various sections of the drum membrane. Functionally, the ear is apparently very gravely involved. Examination of the nasopharyngeal cavities shows an active or retrogressing inflammatory process. The pulse and temperature are comparatively normal. Such a condition may endure from a week up to years, with apparent remissions. Incision of the drum gives exit to no secretion or only to a little. The drum membrane is often so thick and fibrous that considerable force is necessarily exercised. But on forcible inflation the picture is changed. Then there appears in the canal a quantity of stringy, tenacious mucus which follows the cotton on the applicator on its withdrawal from the canal as a long, filamentous string. Repeated and forcible inflations are often necessary to evacuate the drum cavity. After the removal of this exudate the hearing is decidedly improved and remains so until the incision heals and more mucus is formed. Douching of the external ear seems never to do anything but harm. Periodical inflation with treatment of the nasopharynx will in some cases bring about a slow recovery, but the patient usually is too impatient to wait for this, and permanent impairment occurs from inspissation of exudates or the formation of adhesions. The treatment he advises is incision and evacuation of the tympanum, repeated if necessary, always accompanied by regular Politzerization and conscientious treatment of the nasopharyngeal condition. Before the incision, the external auditory canal should be made as nearly aseptic as possible and the nasopharyngeal cavities thoroughly cleansed. After the membrane has been removed, the canal is packed with gauze and a mild astringent application made to the post-nasal mucous membrane. The patient must be seen in from twelve to twenty-four hours and the ear again gently inflated and the gauze packing removed. After this, a treatment, once in every two or three days, is usually necessary. Should the exudate persist in reforming, a solution of nitrate of silver .5 to 1 gr. to the ounce of boiled distilled water, acts favorably, both injected into the Eustachian tube and instilled in the tympanum through the incision.

32.—This article appeared in The Journal of September 7, p. 611.

33.—Ibid., p. 613.

45. **Alcohol.**—Crothers reports several cases where a single intoxication with alcohol seemed to produce permanent effects in persons previously unused to stimulants. He believes that intoxication to the extent of coma with profound relaxation of all the functional activities of the body is often a serious injury to the brain and nerve centers, and is followed by neuroses and organic change. The significance of alcohol intoxication in the study of obscure diseases can not be overestimated. It may be both an active and exciting cause, and should always be considered in neuro-psychopathies or other disorders that follow. The intoxication of puberty or middle life is often the starting of a circle of diseases usually ascribed to other causes. Intoxication always predisposes to the diseases of inebriety from alcohol or opium which may come on suddenly in after-life. Alcoholic poisoning is far more serious than supposed in its effects and the neuroses which follow.

46.—See abstract in The Journal, xxxvi, p. 1727.

47. **Tuberculosis of the Testicle.**—The following deductions are presented as a result of study of this subject by Abell: 1. The epididymis is the most frequent starting-point of the uro-

genital tuberculosis. 2. It is usually secondary to some other focus, but may be a primary deposition. 3. The testicle is rarely primarily affected, but, as a rule, secondarily so from the epididymis. 4. Primary infection usually occurs by the blood-stream, possibly rarely by coitus. 5. When the epididymis is primarily infected through the blood-supply, the process is probably an intertubular one. 6. When secondary to other foci of the urogenital tract, constituting a descending infection, the process is probably intratubular.

63. **Chorea.**—The etiology and pathology of chorea are discussed by Favill. Its nature has been a subject for wide range of speculation; functional, embolic, toxic, infectious and degenerative causes have all been advocated. The early apparent association of chorea with rheumatism has led to the general belief in the allied nature of the two conditions, some holding that rheumatism in general may be the cause, others in rheumatism with endocarditis as a complication. Favill favors the idea that chorea, arthritis, and endocarditis are related to each other and are related to an infectious cause or causes, though he would not say that these are the only causes. He believes that they are co-ordinate manifestations of disease conditions peculiar to the young in the following order, endocarditis, first; chorea, second; and arthritis last, and that infection is usually an important element of the cause.

65. **Bovine Tuberculosis.**—The question given in the title is discussed by Ingals, who credits Koch's view with a certain amount of validity and his proposition certainly seems reasonable, he says, from evidence, but with him he would withhold conclusions until further research can furnish definite proof. In the meantime many of the profession feel warranted in advising their patients not to worry as much as formerly about milk, though no one wishes the care relaxed that is now being taken to prevent the sale of milk from diseased cows, or to prevent consumption from tuberculous beef. He finishes with the suggestion that condemned criminals might be utilized for experimentation to test this question and has no doubt that many criminals who have forfeited their lives would gladly accept the chance to prolong them even within the walls of the penitentiary.

68.—See abstract in The Journal, xxxv, p. 1005.

69.—Ibid., p. 1172.

71.—Ibid., p. 1104.

73.—Ibid., p. 1172.

82. **Interocular Base Line.**—The interocular base line, so-called by Helmholtz, meaning by this the line joining the centers of motion of the two eyes, is sometimes of some value and Howe describes the method of its measurement. It may be of use in curing certain cases of asthenopia and in prescribing proper glasses and centering the lenses. Two methods are here described, for the details of which the reader is referred to the original paper.

85. **Tuberculosis of the Conjunctiva.**—After reporting a case, Hansell gives the data which he has obtained from a perusal of the literature of the subject. He finds that the cause is often self-infection, wiping the eyes with infected articles, metastasis or traumatism. The palpebral conjunctiva is most frequently infected. The tubercles appear in the form of miliary ulcers, of subconjunctival nodules resembling the granules of acute trachoma, hypertrophied papillæ, and pedunculated tumor resembling papilla fibroma. In addition, Sattler mentions lupus as one of the forms. For diagnosis, the evidence of tuberculosis of other organs and the microscopic examination are largely to be depended on, since tubercle bacilli are not often found. Their presence, however, is confirmatory of tuberculosis. Many cases are undoubtedly masked by trachoma and others diagnosed as trachoma are tuberculous. The methods of treatment that have received the strongest endorsement are excision and the galvanocautery. The inflamed section of the conjunctiva and the healthy zone surrounding it should be excised where the case is not inoperable. If the pre-auricular or other glands are involved, they should be included in the operation. If the case has gone beyond the operable stage, the ulcers should be burned by the galvanocautery.

87. **Entropion and Trichiasis.**—Foster's article is largely a review of the literature and the methods of treatment of this condition. He thinks the real progress in surgery of entropion and trichiasis is perhaps embodied in two modifications, of the Celsus operation, the anchorage of the lower flap of the skin to the upper border of the cartilage to secure permanency, and the implantation of a wedge-shaped graft of mucous membrane to prevent the agglutination of the lips of the wound behind the lashes. The popularity of various modern operations, such as Streatfeild-Snellen, and the Jaesche-Arlt, depend largely on the presence of two or more of the principal features of this operation so modified, the shortening of the lid skin, its anchorage to the cartilage, the partial detachment of the ciliary margin and the reformation of the edge of the lid.

93. **Pernicious Anemia in Infants.**—The first part of Rotch and Ladd's paper is largely a discussion of the literature and theories of this condition and a case is reported in detail. The important points emphasized are the insidious onset, with moderate and paroxysmal attacks of indigestion, extreme pallor and loss of strength, absence of any possible demonstrable cause for a secondary anemia, slightly elevated temperature with absence or glandular or splenic enlargement, the presence of pronounced typical characteristics of the blood of pernicious anemia, absence of any considerable degree of leucocytosis, and rapid improvement in the general symptoms and in the character of the blood with apparent complete recovery, which is typical of the remissions which so often occur. While the child may be perfectly healthy to-day as far as can be determined, the fact remains that permanent recovery has never been reported in any well-attested case of pernicious anemia in infants. Several cases of recovery in adults are on record and it is suggested that the great recuperative power in infants' blood may resist the usually fatal tendencies. As regards the treatment of these cases the management of the feeding is of first importance. Arsenic may be tried cautiously and iron in the form of ferratin or similar preparations will do no harm and may be of benefit. Cabot has recently been treating his cases with laxatives or purgatives on the theory that the disorder is due to absorption of toxins from the intestine, but no definite results have as yet been announced. In these cases the inhalation of oxygen was used in large quantities for long periods and immediate and rapid improvement followed its administration. It is difficult, however, to say anything as to the efficiency of special remedies.

94. **Cyclical Albuminuria.**—After noticing the literature and the theories of the disease, Churchill reports a case in detail with urine and blood examinations, etc. He considers that the symptom is a real danger signal not to be slighted and that its cause should be carefully investigated.

95. **Rectal Polypi.**—The etiology of rectal polypi is discussed by Huber who reports the case of an undersized boy, somewhat backward, with pronounced aprosexia due to adenoids. In addition, goiter and moderately enlarged lymph nodes furnished further evidences of the status lymphaticus. The abnormal rectal condition was doubtless a local manifestation of the same nature. He has noticed one feature common in all cases which have come under his observation during the past four or five years, namely, that rectal polypi were found only in patients who at the same time showed other evidences of lymphoid hypertrophies in the nasopharynx, with other manifestations of the status lymphaticus, and he concludes that this can not be a mere coincidence. The reason why they are not more common is, he thinks, possibly because they are unobserved to some extent.

96. **"Fourth Disease."**—Simpson's paper is based on the experience with an epidemic of a peculiar condition of eruptive fever occurring in the School for the Deaf in Hartford. At least five of the patients had a second rash occurring two or three weeks after the first, lasting several days with slight rise of temperature, but no feeling of malaise. Five of the

patients had had previous scarlet fever and 4 of them are said to have had German measles; there had also been a previous occurrence of an epidemic of "pinkeye," mild in character, which he thinks was rubella manifesting itself in this way. The fact of lamellar desquamation in a large proportion of cases which was certainly not scarlet fever, does more than anything else to make credible the existence of another eruptive disease. The form of desquamation is the chief diagnostic point between "fourth disease" of Dukes and rubella.

104. **Classification of Insanity.**—The conclusions of Dercum's article are: 1. All of the mental disorders which result from the infections, the intoxications, the diatheses, the visceral diseases, the diseases of the nervous system, pregnancy, the puerperium, the lactation,—in short, from all of the diseases and morbid physiological states—belong to the symptom group of delirium-confusion-stupor dementia. Delirium, confusion and stupor are largely interchangeable terms possessing a certain degree of equivalence, and it must depend largely upon the activity of the morbid process as well as upon its character as to which of these forms is present in a given case. That secondary differences of symptoms, dependent upon the nature of the infection or the special poison that has been ingested are present, goes without saying, but these differences in no way affect the truth of the general statement. 2. The melancholia-mania syndrome bears no relation to the various infections, intoxications or visceral diseases. Neither mania or melancholia ever results from them. Mania and melancholia are diseases primarily of the nervous system—neuroses so to speak—and are largely hereditary. He thinks that much confusion has resulted from the unscientific use of mania and melancholia and considers that neither of these or paranoia or the neurasthenia-neuropathic insanities bear any relation to internal diseases, but their onset is favored by any causes that are attended by persistent depression of nutrition or by degenerative changes in the nervous system. 3. The delirium-confusion-stupor syndrome may occur at all ages. Melancholia-mania and paranoia, on the other hand, are related to definite periods of life. 4. The delirium-confusion-stupor syndrome usually occurs independently; its forms may, however, occur as complications or episodes in any of the other affections.

113. **Gonorrhea.**—According to Professor Neisser, gonorrhea is curable in all cases that are properly treated. A definite percentage, however, can not be given and cases of posterior urethritis, and prostatic involvement are much more serious, but even here the prospects of rendering the individual non-infectious, though much diminished, are not yet unfavorable. The indications for treatment are to destroy the cause of the disease, the gonococci, by a treatment that must be capable of deep penetrating action, an effective germicide free from astringent qualities and that will not enter into chemical union with albumin, mucin or chlorin of the tissues. Simple astringents are unsuitable in the acute stage and all mechanical and semi-mechanical methods requiring sounds, endoscope, etc., are dangerous. He considers that protargol has a strong germicidal action, and is least irritative, while argonin, oxycyanate of mercury and largin can be used in the later stages. The Janet irrigations where practicable, and prolonged injections are suitable methods of application. The chronic cases should be treated with bactericidal solutions as long as the gonococci are found and sometimes afterwards. The patient should be permitted to marry when, after thorough, complete and often-repeated examinations, the physician is able to state that the gonococci are not found either by provocative mechanical, or chemical measures. This is from a practical rather than from an academical standpoint. Burnett answers also in the affirmative as to the curability of the disease and thinks fully 100 per cent. are curable. He finds local treatment best in the acute cases, giving internal remedies in case of irritating urine or where it is needed to sterilize, and in chronic urethritis. He thinks, however, it is unsafe to depend solely on the disappearance of the gonococcus, and he would make the limit of time before the patient is fit to marry from six weeks to as many months after complete restoration to the normal as far as possible.

122. **Convulsions in Children.**—A convulsion is a symptom, not a disease, often due to inherited nervous conditions. The child is naturally unstable and the symptom may be a reflex from over-stuffing, intestinal poisoning, and disturbed thermogenesis. Acute auto-infection acting on the former produces the eclamptic seizure. According to Dickey the convulsions not infrequently take the place of the rigor in adult life, ushering in the acute infectious diseases and in the hyperpyrexis of such disorders is diphtheria and pneumonia, where it may also occur. In any case he would first use the thermometer, no matter how urgent the symptoms, and if there is a temperature of 103 or more and the extremities are not cold, he believes a hot bath contra-indicated, but that a cold sponge bath should be employed. The stomach tube, an emetic, anema of warm soap suds, should be used, if indigestion is suspected. Under the cold bath, the temperature is lowered, inspiration becomes longer and deeper, more oxygen is taken into the blood and carbonic acid is liberated, the brain centers and nerves are better nourished and the heart is regulated, and the kidneys secrete more urine, carrying off the poisonous products.

124.—See abstract in The Journal of September 14, p. 721.

125. **Suprapubic Lithotomy.**—Lydston remarks that the simplicity of this operation may tempt its performance on the part of surgeons whose technique is faulty and experience small. The statistics of the operation in the hands of one individual constitutes no criterion of the possible mortality rate in the hands of another. There are special dangers of injuring the peritoneum and of extensive laceration of the bladder, as well as of infection, in any case. He thinks, however, there should be no hesitation in choosing this method when stones of considerable size exist, and that with increasing care in the technique, there will be a decrease not only in the mortality rate, but convalescence will be quicker, there will be fewer cases of infection and the danger of hernia will be reduced to a minimum. An improvement in the results, however, can not occur until operators in general have learned that, in spite of the simplicity of the operation from a mechanical standpoint, there are many details of technique to be improved before the ideal operation can be performed. He says there is a question in his mind whether with improved technique it might not come to be the most useful operation of all for stones, not excepting litholopaxy.

128. **Hedonal.**—After discussing the physiology and therapeutic effects and reporting a case in which this drug has been used, Walling comes to the conclusion that the chief disadvantage of hedonal is its disagreeable taste and that its advantages are: "1. Its acceptability to the stomach, as a rule, notwithstanding the above objection. 2. Its positive effect in a majority of cases. 3. It has no injurious aftereffects. 4. Its use may be continued indefinitely, with good results, or it may be discontinued at any time without the fear of the formation of a habit."

135. **Nose and Throat in Medicine.**—Wright continues his historical article reviewing the periods of Hippocrates down to Roman medicine and Celsus.

136. **Subarachnoid Cocainization.**—The use of subarachnoid cocainization for operations on the head is discussed by Payne, who goes into the details of the method and reports cases. To produce anesthesia of the upper extremities he says it is simply required when the needle is injected that it be pointed upward and the cocainized solution be forced in quickly. He has had no bad consequences in his cases except headache, which is sometimes severe but is readily relieved. In no case has there been surgical shock and he endorses the method as having no contra-indications. He has used this method for two simple mastoid operations, one Stacke operation, one frontal sinus operation, one ossiculectomy and one enucleation of the eye.

FOREIGN.

British Medical Journal, September 14.

Observations on Blackwater Fever. F. K. Kleine.—Koch's views as to the quinin origin of blackwater fever are supported here by Kleine, who, at the request of Dr. Koch, reports fifteen cases that appear to support his views. In each of the histories the hemoglobinuria followed more or less immediately the administration of quinin, and the reported instances where it has occurred without quinin are accounted for by him as largely based on the imperfect details of facts. The quinin works on the blood corpuscles already diseased by the malarial infection; a weakened organism is more powerfully acted upon by poisons than a healthy one and other substances than quinin have been reported as causing hemoglobinuria, such as antifebrin and salipyrin. Blackwater fever does not occur in temperate climates, because there we do not have the extensive and unregulated use of the drug as in the tropics, so that we have no idea how the prolonged administration influences the blood composition. Koch's views are not altered from those formerly held; he believes in the majority of cases blackwater fever is the result of quinin poisoning in malarial patients, but at the same time he holds that by means of an appropriate quinin prophylaxis malaria, and with it, in the vast majority of cases, blackwater fever can be stamped out. An imperfect quinin prophylaxis which does not entirely protect against malaria, on the other hand, predisposes to blackwater fever, for in such a case plasmodia and quinin unite to act harmfully on the organism.

Influence of Color Upon Anopheles. George H. F. Nuttall.—This author has investigated the preferences of the anopheles to different colors. It was noticed at the beginning that they settled on dark cloth, but rarely do this upon white flannel. Therefore, a number of pasteboard boxes were taken, lined with cloth of different colors and placed in rows, the order being changed each day after the observations had been made. For seventeen days during the month they counted the number of flies that had accumulated in the boxes and found that the boxes lined with navy blue, dark red, reddish brown, scarlet and black contained far the largest number, navy blue being evidently the preference and the others following in the order mentioned. The smallest numbers were found in the green, violet, light blue, pearl gray, ochre, and orange boxes, but none whatever in pure yellow. Pale green, light blue, ochre, orange and yellow, especially the last two, seemed to repel the insects. The practical deductions from these facts are that the khaki uniform now in vogue has advantages besides being invisible to the human enemy; its color is absolutely repellent to this malaria-bearing mosquito.

A Further Note on the Biological Test for Blood and Its Importance in Zoological Classification. George H. F. Nuttall.—The same author has experimented on 140 samples of blood derived from all classes of vertebrata to test their antiserum reaction. None, except monkey bloods, gave reactions for human bloods and the blood of the old-world monkeys gave much more powerful reaction than that of the American monkeys, indicating the truth of the Darwinian theory of the closer relationship between man and the old-world apes than with the American monkeys. The antiserum for dog's blood only gave reaction for the blood of the jackal (Canis mesomelas). The antiserum for ox and sheep blood only gave full reaction for homologous bloods, besides the slight reactions previously mentioned in an earlier paper. The ox antiserum produces slight reaction in the blood of the goat and a faint cloudiness in that of the roebuck and Burrhel sheep from the Himalayas. The sheep antiserum furthermore gave a marked reaction with the blood of the Burrhel sheep and of another wild species of sheep, a slight but distinct reaction with the blood of the goat, and a faint clouding with that of the roebuck. He thinks it certain that interesting results from the point of view of the zoological classification will be revealed by these tests thoroughly carried out. From a medicolegal standpoint the tests should be applied to as large a number of bloods as possible. He describes the method, which is simple; just saturate filter paper and dry it, and it makes no difference whether the blood is from a recently dead or living animal.

Inoculation and the Incubation Stage of Plague. W. B. Bannerman.—Calmette is reported to have given his opinion that in a person in the incubation stage of a slight attack of plague we should find the disease rendered grave if at this period a preventive inoculation of the Haffkine vaccine was given, and the case would almost certainly end fatally. Bannerman has investigated this subject statistically, taking the facts that he could collect from different Indian stations and finds that this statement is not borne out. In fact, it is manifest, he says, that there is very little difference between the percentage case-mortality in those attacked respectively before and after the first ten days' period subsequent to inoculation. The figures seem in fact to point to a sudden and very considerable measure of protection being secured after the lapse of twenty-four hours only, though this desirable effect increases with lapse of time.

A Discussion on Stone in the Tropics. P. J. Freyer.—In opening the discussion on stone in the tropics, Freyer accounts for the frequency of stone in India by the geological conditions and drinking water. The regions where stone is most frequent are those were lime salts are in solution in the drinking water and find their way into the system, being deposited in the urinary tract in the form of oxalate of lime; or by causing derangements of the digestive system, lead to the formation of uric acid and urates in excess and eventually to deposits of crystals in the urinary passages, resulting in the formation of stone. The climatic condition also favors this. These special regions are characterized by scantiness of rainfall as compared with the rest of India; great alterations in the temperature, scanty rainfall and intense heat promote excessive perspiration, most of the fluids of the body passing off in perspiration and thus leading to concentration of urine which is likely to facilitate the deposition of crystals. Food and feeding, he thinks, have less influence. He believes the Indian experience shows the great advantage of Bigelow's litholopaxy operation over all other methods.

The Lancet, September 14.

Changes Effected by Antityphoid Inoculation in the Bactericidal Power of the Blood. A. E. Wright.—A summary of the facts brought out in Wright's article is given by him in the following practical conclusions: With regard to the sequence of events after an anti-typhoid inoculation it has been shown: 1. That where the quantum of anti-typhoid vaccine employed produces the familiar, well-marked constitutional symptoms a decrease in the bactericidal power of the blood and a corresponding increased susceptibility to typhoid infection may supervene in the period immediately subsequent to inoculation. Upon this negative phase of increased susceptibility there may, however, be expected to succeed, probably within a period of three weeks or less, a phase of increased bactericidal power and a greater resistance to typhoid. 2. That when the quantum of anti-typhoid vaccine employed produces very severe constitutional symptoms a negative phase of increased susceptibility will be produced which—and the same would appear to hold true also in case of a negative phase supervening upon an actual attack of typhoid—may never be followed up by a positive phase of increased resistance. 3. That when the quantum of anti-typhoid vaccine employed is reduced to the point at which marked constitutional disturbance is avoided a positive phase of increased resistance may be expected to supervene without the intervention of any negative phase, and in many cases within twenty-four hours. The practical conclusions are, therefore: 1. The employment of primary inoculation of large doses of vaccine—enough to give rise to severe constitutional symptoms, seems inadvisable and would probably be associated with danger in the actual presence of a typhoid epidemic. 2. The employment of a moderate dose of vaccine giving rise to marked, if not unduly severe symptoms would also appear to be inadvisable in the actual presence of a typhoid epidemic, but might be appropriately employed where an interval of several weeks is to elapse before exposure to infection and where there are difficulties in the way of carrying out two successive inoculations. 3. The employment of small doses of vaccine producing only a slight constitutional disorder appears to be the only form of typhoid inoculation in the actual presence of an epidemic, and seems also in all other cases the most appropriate method. Such primary inoculation, however, ought always to be followed by a second inoculation, with an increased dose of vaccine. Of subordinate importance are the following: 4. Where the blood of a patient who has recovered from typhoid fever is found to possess a bactericidal power inferior to the average, and where re-exposure to typhoid is contemplated, it would seem advisable to secure for the patient the additional protection associated with possession of a high bactericidal power. This additional security can, if it is permissible to generalize from the observation detailed in one of the cases reported, be conferred by the inoculation of an appropriate quantum of anti-typhoid vaccine. 5. On the other hand, where the blood of the patient who has recovered from typhoid is found to possess a bactericidal power considerably above the average, it wound, taken together with certain other data, appear to be impracticable to increase the bactericidal power by the inoculation of sterilized cultures. 6. Wherever a doubt as to the efficiency of a particular anti-typhoid vaccine arises—and such doubts may obviously arise, either in connection with modifications introduced in the methods of preparing the vaccine or in connection with prolonged storage under unfavorable circumstances—it will always be possible to arrive at a decision of the efficiency of the vaccine by observing the effect exerted by the vaccine in question on the bactericidal power of the blood. He concludes that there appears to be a very definite limit beyond which the bactericidal power of the blood can not, it would seem, be increased by inoculation with sterilized cultures of the typhoid bacillus.

The Postoffice and the Prevention of Tuberculosis. Charles H. Garland.—From an investigation of statistics of an insurance society composed entirely of postoffice officials, numbering nearly 20,000, Garland finds that the amount of deaths from tuberculosis between the ages of 15 and 65 years number 45 per cent. Considering that these are selected lives, he thinks they point to a general contamination of postoffice buildings, and he suggests the use of prophylactic measures; the absolute prohibition of spitting, thorough disinfection, if possible, the disuse of dry sweeping, thorough weekly washings of the floors and a rigid exclusion of tuberculous subjects and tuberculous suspects by more rigid examination. The employés should be taught the causes and modes of prevention of tuberculosis; printed notices should be put up. These recommendations are largely quoted from a French report on the subject, which deals with the same conditions in French postoffices.

Presse Medicale (Paris), September 7.

Indications for Phototherapy. Leredde.—The efficacy of light therapy is due to the remarkable penetrating power of the chemical rays, which act on the lower strata of the integument, without destruction of tissue. There is none of the irregular action which renders the Roentgen rays so treacherous at times. The reaction is not painful, the cicatrices are perfect, and the blisters which form in the course of the treatment of lupus contain an alkaline fluid loaded with eosinophile cells. Leredde is convinced that the Lortet apparatus is a great improvement over Finsen's. It was described and illustrated in The Journal of July 20, p. 229. By the discovery of phototherapy, lupus has become an affection which should be regularly and normally cured. It fails in the advanced, intractable cases, but henceforth, no case of lupus should be allowed to reach this intractable stage. The physician should treat it early, and inspire the patient with the energy to complete the cure. Galvano-cauterization and scarification may be tried first, for a limited time, and then suspended to watch the results. If the lupus continues a progressive course, phototherapy should be applied, without waiting for the former measures as their prolonged use causes cicatricial formations which impede the action of the chemical rays. When the lesions are on the limbs or trunk they are usually very extensive and other measures are preferable. In case of erythematous lupus, if it is the aberrant form, salicylic and pyrogallic acid, mercurial plasters, high frequency electricity and scarifications are able to accomplish the cure. Phototherapy is not indicated except in those cases in which the lupus patch recurs year after year at the same point, in spite of these measures. Fixed erythematous lupus offers the same therapeutic problem as ordinary lupus, and consequently phototherapy is equally effective as in the latter. Electricity may also have a curative influence, but superficial applications are useless. Even after apparent cure, the lesions may recur again and again, and it is necessary to continue the phototherapy until complete sclerosis is obtained. All lesions of the face rebellious to other measures, may be cured by phototherapy. Finsen has cured one patient with extensive vascular nevi and improved nine others. Leredde has been much encouraged by his success in a few cases of this kind. One patient with a nevus occupying one entire side of the face, with a few patches on the other, was treated by phototherapy and the small patches were cured, but the other side was not affected. Another patient has been entirely cured of a number of patches on his chin. Phototherapy, therefore, will cure the less extensive nevi, without much thickening of the tissues, but is powerless—as at present applied—against the most pronounced cases. He has cured three cases of acne rosacea which had resisted all other treatments, applying the phototherapy very gradually and tentatively. He has also found it effective in extensive, almost chronic sycosis. He is now studying its action on buccal leucoplasia and alopecia areata. It is only exceptionally indicated for an epithelioma of the face, but may prove very valuable in rare cases. A patient with an old lupus of the temple and upper lid and eight or ten fresh epitheliomatous foci, was completely cured with two months of phototherapy.

September 11.

Regulating Apparatus for the Composition of the Blood. C. Achard.—When the natural emunctories are insufficient from any cause, the blood evacuates its waste products into the depths of the tissues, into the interstitial lymphatic circulation, the intercellular plasma and, possibly, into the protoplasma of the anatomic elements. These substances poured out into the tissues do not remain there permanently, but gradually find their way back into the blood, and are eliminated by the natural emunctories little by little. The molecular concentration changes less than the chemical composition and returns to normal more rapidly. The cycle of circulation in the blood of ingested chlorids, for instance, may have completed its evolution before the cycle in the extravascular circulation has commenced, and this fact aids in the regulation of the blood. The motive power controlling this regulating mechanism must be derived from the nervous system, and consequently therapeutics should aim to influence the latter rather than the blood itself. The assumption of this regulating mechanism explains the contradictory findings in cryoscopy. The blood is only transiently affected by insufficiency of the emunctories, the waste products are poured out into the depths of the tissues, and excite a reflux of fluids. There is a periodical interchange and when the emunctories function normally again, the solid substances are eliminated en masse. This is seen, for instance, in the excessive amount of chlorids voided after the crisis of an infectious disease.

Progres Medical (Paris), September 7.

Ovarian Treatment. E. Vidal.—The ovary of sheep seems to be the best adapted for organ therapy, as it obviates the danger of tuberculosis which is so frequent in cattle. The ideal would be to take the ovaries from rutting animals, but this is seldom practicable at present. Vidal prefers the subcutaneous route to administration by the mouth, and has found ovarian therapy very effective in the natural or artificial menopause and in neurasthenia in women. The injection of the glycerin extract is made in the buttocks on a line passing from the last sacral vertebra to the upper margin of the great trochanter. He applies an air-bulb to facilitate the injection of the fluid from the fused tube which holds only the exact amount to be injected, from .5 to 5 c.c.

Centralblatt f. Chirurgie (Leipsic), September 7.

Automatic, Weighted Retractors. G. De Francisco.—The Journal mentioned at the time the fine results reported by Tansini from the use of gold wire in suturing after herniotomy. He reduces the number of assistants and prevents all digital contact with the tissues by three new instruments illustrated in this communication. One is a broad, curved retractor which is hung like a hook over the spermatic cord, and by its weight of 146 gm. holds it automatically and permanently out of the way. Another rake-shaped retractor, weighing 250 gm., is applied to the edges of the aponeurosis of the external oblique on each side, and holds them firmly in its curved teeth. A long and narrow spade with a long handle bent in the shape of an L, is used by the assistant to press down the parts below the field of operation. Tansini now reports a series of 120 herniotomies in which the gold wire and these instruments were used, and none showed a trace of suppuration or recurrence. The quantity of wire needed is very small and the expense trifling. As it is left in the tissues it obviates all danger of a relapse.

September 14.

Slitting Thrombosed Varicose Veins. W. Kramer.—Instead of extirpating the thrombosed varicose vein in the leg, Kramer merely slits it throughout its entire length and extracts the clots. In fifty patients thus treated, the lips of the wound in the vein closed spontaneously and healed without reaction. The patients were relieved completely of all their former troubles from this source. The lumen of the veins had become obliterated in the thrombotic process and consequently there was no bleeding nor symptom of embolism.

Deutsche Med. Wochenschrift (Leipsic), September 5.

Auto-Intoxication in Epilepsy. Hebold.—After four years of experimental research on dogs and white mice, Hebold announces that he was never able to establish any regular parallel between the toxicity of the organic juices of epileptics and their seizures. The blood and urine of epileptics during and between the seizures were injected subcutaneously into hundreds of animals, but the results fail to confirm the assumption of a morbid metabolism as the cause of epilepsy. The only positive result attained was that in a few cases the tests showed a condition of auto-intoxication, which was apparently the determining factor for a seizure in these patients.

Disinfection of Surgical Instruments with Tincture of Soap. J. H. Polak.—Delicate sharp instruments are injured by being boiled. They can be disinfected without injury by tincture of soap, which Mikulicz recommends for disinfection of the hands. It is bactericidal and rapidly dissolves pus and blood. Straub has been using it for more than six months in his clinic and has found it very convenient and effective, with no disadvantages. After an operation he puts the sharp instruments in the tincture of soap for fifteen minutes and then cleanses them. Before the next operation he soaks them in tincture of soap for fifteen minutes and then rubs them carefully with a sterile linen rag, dipped in the tincture. This combination of the chemical and mechanical action of the tincture has proved extremely satisfactory. The instruments can be wrapped in cotton impregnated with the tincture.

September 12.

Suture of Heart Through Right Side. I. Watten.—The stab-wound in the heart extended into the right pleura and was accompanied by a large pneumo-hemothorax. The third and fourth ribs on the right side were resected close to the sternum and turned back, the flap extending from the lower margin of the second rib into the fourth interspace. The lung was covered with a gauze compress and pulled up out of the way with a long-handled retractor. The wound in the pericardium was enlarged and two stout silk threads passed through its edges. By pulling on these threads the heart was drawn well into view, showing the wound in it, about 2 cm. long, through which dark blood was trickling. The top of the wound was close to the base. The heart was hurled to and fro in the pericardium during its contraction and all efforts to insert the needle failed, until Watten seized the heart with two fingers from behind and pressed it gently against the sternum. This held it a little more quiet and a stitch was passed through the lips of the wound. The pause seemed to be lengthened as the needle was inserted, and the contractions followed at longer intervals when the heart was drawn up against the pericardium by pulling on the thread. As soon as it was released, it began to pulsate more rapidly again. Two other stitches were taken and the threads tied. The bleeding ceased and the pulsations were considerably longer. The entire posterior and anterior surface of the heart, except the apex, could be palpated with the introduced forefinger. Two strips of gauze were left in the wound in the pericardium, one above and one below; the pleural cavity was loosely packed with gauze, the skin and bone flap replaced and sutured except where the gauze emerged. This portion was also lightly sutured to prevent the coughing out of the gauze. When the drain in the pericardium was renewed, about 100 c.c. of a sero-sanguine effusion was evacuated two days in succession, after which recovery proceeded rapidly, and the patient is now completely restored, able to do the severest physical work. Watten was amazed at the ease with which the heart could be drawn up into the wound and sutured from the right side. He thinks that resection of the sternum is absolutely unnecessary in case of wounds of the heart.

Fungus Colonies in the Stomach. M. Einhorn.—In six cases of hyperchlorhydria or gastralgia with normal or diminished secretion of gastric juice, Einhorn discovered large quantities of a fungus in the stomach. It was evidently colonizing there as the mycelium, spores, etc., were found numerous when the stomach was empty as well as after eating. Lavage of the stomach, followed by spraying with a 1 or 2 per 1000 solution of nitrate of silver, evidently improved the patient's condition, and it seems plausible that the morbid process, if not caused by the fungus, was at least aggravated by it.

Muenchener Med. Wochenschrift, September 3.

Surgical Treatment of Strictures of the Lachrymal Ducts. Passow.—By slitting the duct from inside the nose it is possible to cure existing stenosis and stricture without a scar and with very little danger of recurrence. Passow has had occasion to perform this operation only four times, but the success was striking in each. Tests on the cadaver have shown that the operation is practicable even with a very narrow nasal passage. One assistant must hold the speculum absolutely still, while another wipes the blood. In some cases, removal of the lower portion of the inferior turbinate bone will render the duct permeable and avoid the necessity for further intervention. For this reason it may be well to wait for the results of this intervention before proceeding to slit the duct. Passow prefers the chisel and believes that there is less danger of recurrence of the stricture when the incision is carried into the sac. In two of his cases the operation cured the oozing; the others are too recent for a definite conclusion.

Acid Intoxication in Diabetes Mellitus. O. Busse.—Three cases of fatal diabetes mellitus are described, in which the kidneys, heart and liver presented the same "boiled" appearance noticed after intoxication with dilute mineral acids. Acids are generated in diabetes, especially betaoxybutyric acid, to such an extent that the alkalinity of the organs and of the blood is completely neutralized, and the acids circulate freely and uncombined in the organism. It is therefore probable that coma and death in diabetes may be due to the injurious effects on the organs of this excess of acid entailing a fatal acid intoxication.

Paraffin Injections in Facial Atrophy. A. Luxenberger.—The deformity resulting from progressive facial hemiatrophy in two young women was completely cured by the injection of paraffin according to Gersuny's directions. One case was very extensive, requiring fourteen injections of small amounts of the paraffin in the brow, temple, nose and cheeks, with massage afterward to model the parts symmetrical with the other side.

In the second case the atrophy was restricted to the lower jaw and four injections were sufficient to restore the cheek to its normal outlines. There was a slight smarting after each injection, with the sensation of a foreign body in the cheek, but this all passed away in the course of half a day. The mixture of hard and soft paraffin, called in Germany "white American vaselin," which is used for these injections, does not produce irritation even when comparatively large amounts are used. Straume found that animals tolerated three to ten grams per kilo of the body weight. In Luxenberger's two cases the appetite, pulse, temperature, respiration and urine showed no trace of disturbance during the course of the injections.

Malignant Tumors of the Tonsils. HEINLETH.—Heinleth describes a case of a round-celled sarcoma, 4 cm. long by 2 wide and 2 thick, removed from the throat of a robust man. It was followed by a recurrence in a month, which was likewise extirpated. Twenty-three months have since passed and there are no suggestions of further recurrence. The patient weighs 172 pounds and a linear scar is the only trace of the operation. He removed the tumor by the Kroenlein-Langenbeck method, the incision starting at the corner of the mouth and curving downward over the horizontal ramus of the lower maxilla to the cornu of the hyoid bone and thence upwards to the rear margin of the mastoid process. The maxilla was divided at the second molar. The glands were enucleated, the arteries exposed and the lingual artery ligated. The maxilla was then twisted still farther out of the way and the mouth entered, after placing the patient with his head pendent over the edge of the table. The anterior and posterior pillars to the base of the tongue, the right half of the posterior pharyngeal wall and a portion of the soft palate and of the uvula were removed with the tumor. The defect was partially closed by drawing the mucous membrane of the cheek and of the pharynx nearly together. The open portion was tamponed, the maxilla sutured with silver wire and the skin with catgut. The patient was encouraged to get up the second or third day and the wound rapidly healed. He was able to swallow liquid food almost from the first. The avoidance of tracheotomy and the simplicity of the after-treatment are the chief advantages of this method of intervention. The recurrence was removed by the cautery through the mouth.

September 10.

Floor Infection of Young Children with Tuberculosis. DIEUDONNÉ.—Fifteen children between six months and two and one-half years old, who played on the floor in poverty-stricken homes where one or both of the parents was tuberculous, were examined to see if tubercle bacilli could be discovered on their hands or nasal membrane. Nearly 90 guinea-pigs were inoculated and virulent tubercle bacilli were found on the hands of two of the children and in one in the nose.

Wiener Klin. Wochenschrift, September 5.

Treatment of Hourglass Stomach. K. BUEDINGER.—A patient exhibited the symptoms of hourglass stomach on a cicatricial basis, and was operated on, but no traces of the supposed hourglass shape were discovered. The pylorus was permeable for the finger and soft. A fibrous adhesion connected the pyloric region with the omentum, and a small T-shaped scar was noted on the anterior surface of the stomach, about 6 cm. from the pylorus. As this was being palpated, the stomach suddenly contracted and assumed under the operator's eyes the typical hourglass shape, the pyloric region forming a tumor, closing its lumen completely. The tumor subsided after five seconds and the phenomenon was repeated twice in five minutes. It demonstrated that spastic pylorus tumors are in fact due to the contracture of the antrum or of the antrum plus the pylorus, and that the apparent hypertrophy is merely the rigidity of the contracture. In this and similar cases, when the hand was placed over the lesser curvature and the greater was pressed with the other hand, it was possible to perceive a trickling of fluids from one into the other as through a very narrow aperture. In cases not adapted for gastroenterostomy, favorable results may be attained by incising the stomach at the edge of the greater curvature, carrying the incision equally high on both the front and rear surfaces of the organ. The edges of the incision are then sutured together which restores the stomach to nearly normal shape. This operation was performed on one practically moribund patient with excessive hematemesis, but she succumbed soon afterward. The operation, however, established the feasibility of this technique.

September 12.

The "Ether Drunk" in Its Practical Application. F. TEWELES.—Relaxation and analgesia follow ten or fifteen deep inhalations through the ether mask on which from 10 to 30 c.c. of a mixture of balsamic oil and ether have been poured. The operation can thus be commenced within a minute of the first administration of the ether. In about a third of the 157 cases operated on by this technique at the Vienna Rudolfinerhaus, the patient made some slight repelling movement and then quieted at once. In but very rare cases was it necessary to administer another 10 c.c. One patient who was making vigorous defensive movements with her arms, held the leg on which the operation was being performed, perfectly still. The flask first used holds 30 c.c., the others 10 c.c. each, and it is seldom necessary to use more than one or two of the latter, even in very protracted operations. It is possible to keep patients thus "drunk" for an hour with as little as 110 c.c. of the ether. The operator aims to keep the patient on the narrow borderland between awaking and the manifestation of the stage of excitement. The appearance of the patient is that of a man "dead drunk." This "ether rausch" has nothing in common with ether narcosis except the substance employed. The preparation of the patient consists merely in fastening his attention exclusively on the narcosis. This method of anesthesia is practicable in two-thirds of all operations. If it fails, for any reason, it can be supplemented by ether or chloroform, transforming it into an actual narcosis, and even in this case, it has advantages over the latter alone. As such minute amounts of ether are used, it is absolutely harmless. The disadvantages are that many patients scream and make a disturbance, although they do not experience the slightest pain. Sometimes they make a defensive movement at the first touch of the instrument. Certain nervous patients are too excited to concentrate their attention on the narcosis and this method is liable to fail in their case and also in case of hard drinkers. But these disadvantages are too slight to prevent the general adoption of the "ether rausch," which will certainly follow the recognition of its harmlessness and effectiveness, and a better knowledge of the cases to be excluded.

Gazzetta degli Ospedali (Milan), September 8.

Interrupted Centrifugalization for Sedimentation of Urine. E. U. FITTIPALDI.—A simple method of freeing urine from muco-pus cells, which sometimes completely obscure the microscopic field, is to rotate the centrifugal apparatus fifty times and then pour off the supernatant fluid. Physiologic salt solution is added in its place and the centrifugalizer rotated again for about twenty times, and then again for ten, substituting the salt solution each time. By this interrupted centrifugalization all the muco-pus cells are poured off in the supernatant fluid, leaving all the elements needed for the diagnosis of nephritis, etc.

Serodiagnosis in Tuberculosis. F. DE GRAZIA.—The serum of many animals entirely free from tuberculosis proved capable of agglutinating homogeneous cultures of the tubercle bacillus in the research described by De Grazia. He found also that agglutination was produced not only by the serum of tuberculous patients but also by that from normal persons and from patients with various diseases. Serum from tuberculous subjects has also marked agglutinating power on cultures of other bacteria, the staphylococcus, typhoid, diphtheria and other bacilli. The agglutinating reaction is intense in progressing, advanced tuberculosis, and is perceptible even in the incipient stages, although there is no strict parallel between the degree of agglutination and the stage of the disease. It occurs with killed cultures, but very much more slowly. The agglutinating reaction, therefore, has little, if any, specific diagnostic significance.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

Holden's Anatomy. A Manual of the Dissection of the Human Body. Edited by John Langton, Surgeon to, and Lecturer on Anatomy at, St. Bartholomew's Hospital. Seventh Edition. Revised by A. Hewson, M.D., Demonstrator of Anatomy, Jefferson Medical College, Philadelphia. In Two Volumes. Vol. 1. Scalp, Face, Orbit, Neck, Thorax, Upper Extremity. 153 *Illustrations*. Vol. II. Abdomen, Lower Extremity, Brain, Eye, Organ of Hearing, Mammary Gland, Scrotum and Testis. Illustrations. Cloth. Pp. 843. Price, $1.50 per volume. Philadelphia: P. Blakiston's Son & Co. 1901.

Surgical Technic. A Text-book on Operative Surgery. By Fr. von Esmarch, M.D., Professor of Surgery at the University of Kiel, and E. Kowalzig, M.D., Late First Assistant at the Surgical Clinic of the University of Kiel. Translated by Professor Ludwig H Grau, Ph.D., Formerly of Leland Stanford University. and William N. Sullivan, M.D., Formerly Surgeon of U. S. S. *Corwin*. Edited *by Nicholas Senn*, M.D., *Professor of Surgery at Rush Medical* College. With 1497 Illustrations and 15 Colored Plates. Cloth. Pp. 866. Price, $7.00. New York: The MacMillan Co. 1901.

Manual of the Diseases of the Eye, for Students and General Practitioners. With 275 Original Illustrations, Including 36 Colored Figures. By Charles H. May, M.D., Chief of Clinic and Instructor in Ophthalmology, Eye Department, College of Physicians and Surgeons, N. Y. Second Edition, Revised. Cloth. Pp. 408. Price, $2.00. New York: Wm. Wood & Co. 1901.

Diseases of the Stomach and Their Surgical Treatment. By A. W. Mayo Robson, F.R.C.S., Member of Council and Hunterian Professor Royal College of Surgeons of England, and B. G. A. Moynihan, M.S. Lond., F.R.C.S., Assistant Surgeon Leeds General Infirmary. Cloth. Pp. 308. Price, $3.50. New York: William Wood & Co. 1901.

A Manual of Determinative Bacteriology. By Frederick D. Chester, *Bacteriologist of the Delaware College Agricultural Experiment Station*. Cloth. Pp. 401. Price, $2.60. New York: The MacMillan Co. 1901.

What a Young Wife Ought to Know. Thousand-Dollar Prize Book. By Mrs. Emma F. Angell Drake, M.D., Graduate of Boston University Medical College. Cloth. Pp. 288. Price, $1.00. Philadelphia: The Vir Publishing Co.

Claude Hartland. The Story of a Life: For the Consideration of the Medical Fraternity. Cloth. Pp. 141. Price, $1.00. St. Louis, Mo.: Lewis S. Matthews & Co.

Physicians' Clinical Chart and Fee Book. By Walter Key, M.D., Pilger, Neb., Member of American Medical Association. Volume I. Leather. Price, $1.00.

Queries and Minor Notes.

MEDICAL LAWS.

Clutier, Iowa, Sept. 18, 1901.

To the Editor:—Will you please inform me of the requirements to practice medicine in Colorado? Is a diploma sufficient or is an examination also required? M. B.

Ans.—A diploma or other satisfactory evidence of graduation from a regularly chartered medical school recognized by the Board, or an examination, is required.

Rib Lake, Wis., Sept. 20, 1901.

To the Editor:—Would you please quote me the medical law of Montana? O. E. W.

Ans.—Montana requires a satisfactory diploma and passing of examination. Write to Secretary of Board of Examiners, Dr. Wm. C. Riddell, Helena.

Brenham, Texas, Sept. 23, 1901.

To the Editor:—Will you please give in the next issue of The Journal the law governing the practice of medicine in the State of Louisiana, and the name of the president and secretary of Examining Board? J. B. Y.

Ans.—Louisiana requires a diploma from a medical college in good standing as determined by the State Board, and a satisfactory examination. The secretary of the Board is Dr. F. A. Larue, 624 Gravier St., New Orleans.

SCHLEICH'S LOCAL ANESTHESIA.

Macon, Ga., Sept. 16, 1901.

To the Editor:—Will you please state in the next issue of The Journal the nature of Schleich's local anesthesia?

Ans.—Schleich's method consists in the local injection, into the corium and around the field of operation, of a weak solution of cocain, morphin and chlorid of sodium, producing an edema of the skin. Several solutions of different strength of cocain and morphin are used. The following is Schleich's second solution and most commonly employed, according to the International Text-Book of Surgery: Cocain muriat., .10; morph. muriat., .025; sodii chlorid., .20; aq. destil., ad 100. Sterilize and add gtt. ii of 5 per cent. carbolic acid. The stronger solution No. 1 has twice as much cocain, and No. 3 has only .01 cocain and .005 morphin, the sodium chlorid remaining the same in all three. If other structures than the skin are to be anesthetized the injections are made correspondingly deeper. Eucain has been extensively substituted for cocain, it is claimed, to much advantage.

The Public Service.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Sept. 19, 1901:

P. A. Surgeon J. O. Cobb, granted five days' extension of leave of absence from Sept. 13, 1901.

P. A. Surgeon Rupert Blue, granted five days' extension of leave of absence.

P. A. Surgeon J. A. Nydegger, relieved from duty at Cape Charles Quarantine and directed to proceed to Cairo, Ill., and assume temporary command of Service during absence of P. A. Surgeon J. H. Oakley, on leave. Granted two days' leave of absence from Sept. 10, 1901.

Asst.-Surgeon J. F. Anderson, directed to report to Medical Officer in Command, Immigration Service, New York City, for duty.

Asst.-Surgeon C. W. Wille, directed to assume command of service at Cape Charles Quarantine, relieving P. A. Surgeon J. A. Nydegger.

A. A. Surgeon G. N. Barnesby, granted leave of absence for one month from Sept. 1, 1901.

A. A. Surgeon R. E. Ebersole, granted three days' extension of leave of absence from Sept. 9, 1901.

A. A. Surgeon J. W. Stevenson, granted leave of absence for sixteen days from Sept. 9, 1901.

A. A. Surgeon W. S. Walkley, granted three days' leave of absence from Sept. 12, 1901.

A. A. Surgeon Juan R. Xiques, granted leave of absence for thirty days from Sept. 1, 1901.

Sanitary Inspector J. Y. Porter, directed to visit Key West, Miami, Jacksonville, Fernandina and Mayport, as appraiser.

Hospital Steward L. W. Ryder, directed to report to Director of Hygienic Laboratory for temporary duty.

Surgeon Eugene Wasdin, relieved temporarily from command of the service at Buffalo, N. Y., and assigned to special duty with the President—Sept. 13, 1901. Detailed to represent the service at meeting of American Public Health Association, September 16-20.

Surgeon W. J. Pettus, granted leave of absence for two months from September 15.

Surgeon R. M. Woodward, detailed to represent the service at the meeting of the American Public Health Association, September 16-20.

P. A. Surgeon M. J. Rosenau, detailed to represent service at meeting of the American Public Health Association, September 16-20. Granted leave of absence for one day, September 14.

Asst.-Surgeon Dunlop Moore, relieved from duty at Nome, Alaska, and directed to proceed to the States and await orders.

A. A. Surgeon G. H. Altree, granted leave of absence for fourteen days from September 9.

A. A. Surgeon J. G. Stanton, granted leave of absence for eighteen days from September 13.

A. A. Surgeon W. O. Wetmore, directed to assume temporary command of service at Buffalo, N. Y., during absence of Surgeon Eugene Wasdin on special detail.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Sept. 21, 1901:

SMALLPOX—UNITED STATES.

Illinois: Freeport, Sept. 7-14, 1 case; Peoria, Aug. 1-31, 24 cases.
Maine: Portland, Sept. 7-14, 1 case.
Massachusetts: Boston, Sept. 7-14, 2 cases.
Nebraska: Omaha, Sept. 7-14, 1 case.
New Jersey: Newark, Sept. 7-14, 4 cases, 1 death.
New York: New York, Sept. 7-14, 3 deaths.
Pennsylvania: Sept. 7-14, Erie, 1 case; Philadelphia, 25 cases. 4 deaths.
Utah: Salt Lake City, Sept. 7-14, 4 cases.
Washington: Tacoma, Sept. 1-8, 1 case.
Wisconsin: Green Bay, Sept. 8-15, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, Aug. 24-31, 1 case.
Belgium: Antwerp, Aug. 24-31, 3 cases, 2 deaths.
Colombia: Panama, Sept. 2-9, 12 cases.
France: Paris, Aug. 24-31, 3 deaths.
Great Britain: London, Aug. 24-31, 74 cases, 7 deaths.
India: Bombay, Aug. 13-20, 1 death; Calcutta, Aug. 10-17, 1 death; Madras, Aug. 10-16, 9 deaths.
Italy: Messina, Aug. 24-31, 3 cases.
Mexico: City of Mexico, Aug. 25-Sept. 1, 1 case.

SOME UNUSUAL FEATURES OF APPENDICITIS AND THEIR TREATMENT.*

ERNEST LAPLACE, M.D.
PHILADELPHIA.

The protean character of various forms of pathological conditions, grouped under the head of appendicitis, offers the surgeon an unusual and often unforeseen group of clinical, as well as pathological, manifestations. The varying size and anatomic appearance of the appendix, the various movements through which it passes in peristaltic action, the various directions in which it might permanently locate itself, from the adhesions it is likely to make during the course of a surrounding inflammation, make the possible resulting pathological lesions almost numberless. Should a case be submitted to operation a very short time after the initial symptoms present themselves, the purpose of this paper would be eliminated, for nothing would be found but a displaced appendix adherent to the colon, ileum or retroperitoneum. Possibly when an anomaly takes place, an adhesion to surrounding organs might be found, and the operation or cure of the condition would consist simply in a careful dissection of the adherent and inflamed appendix. Not until the profession and the laity are convinced of this fact will there disappear from clinical surgery the complicated and distressing cases, which, unfortunately, form the subject of these lines. As on a former occasion, I repeat the following proposition: "In every case of fatal appendicitis, there was a time when, had the operation been performed, the patient would have survived." This is true no matter what complications or unusual phases the peculiar anatomic conditions of the case would likely produce in the eventual course of the disease. Granting, as we know, that the first symptoms of appendicitis are persistent pain, even after evacuation of the bowel, and that, therefore, at that stage, nothing more than a mere adhesive peritonitis or perityphlitis ought to be as yet the pathological lesion. Neither the profession at large nor the laity have yet realized the truth of this proposition, and it follows and possibly will continue to follow, that various anomalies in a case will result from certain unusual complications, some few of which I desire to draw your attention to at present.

CASE 1.—A young man, aged 26, complained of constant pain in the left iliac region, the character of which seemed almost like that in acute intestinal obstruction. A differentiation was made by the attending surgeon, who promptly obtained an evacuation by the administration of salines. After slight relief of the condition, the pain returned with redoubled intensity. Rigidity, however, existed in the right iliac region, the pain being distinctly in the left. This made the diagnosis uncertain, and hence a medical treatment was persisted in, with only an increase of the pain, elevation of temperature and increase of pulse. Three days after the appearance of the pain the patient was taken to the Medico-Chirurgical Hospital, and was immediately submitted to operation. A mass was found adherent to the anterior parietal peritoneum, and, with difficulty, separated. Evidences of radiating peritonitis existed, and, as yet, no pus had formed, although the end of the appendix presented a gangrenous appearance while fastened to the peritoneum. The appendix was dissected away, cut at its base flush with the colon, and the edges inverted, treating the opening as a gunshot wound of the abdomen. The surrounding adhesions were scraped and disinfected with a gauze sponge, dipped in a 1 to 1000 bichlorid of mercury solution, and the surrounding parts carefully packed with iodoform gauze. The patient made an uninterrupted recovery.

The lesson learned in this particular case was the reflex character of the pain, which the patient insisted he felt on the left side, tending to deceive the surgeon. The persistent induration of the abdominal walls on the right side, showing a local reflex contraction, together with a return of the pain after copious evacuation, eliminated any direct intestinal obstruction, and pointed out the existence of a local intraperitoneal irritation directly under the indurated muscle. In this connection we should remember that the law of reflexes is varying and deceptive, whereas, the law by which a muscle that is irritated, contracts and becomes indurated, is positive, constant and unchanging. Hence, rather than be led to the operative procedure by the uncertain character of the pain, it is wiser to base our opinion upon the positive evidence of the induration of the muscle in a certain locality, though the pain be felt at a distance.

CASE 2.—A man, aged 42, was taken to the Medico-Chirurgical Hospital, suffering with what his attending physician supposed was an abdominal tumor on the right side, encroaching upon the right inguinal region. There had been no acute manifestations, though the patient had long complained of obscure pains in that region. The temperature ranged between 99 and 100, while the pulse was about 90, the patient being somewhat emaciated. Physical examination revealed an indurated mass, immovable and not circumscribed. There was a tendency to diarrhea in the case. The blood count was taken, 20,000 white blood corpuscles were found to a cubic millimeter, thereby not giving us much information so far as the relation of leucocytosis to the formation of pus was concerned. The peritoneum was opened by a line of incision, extending from the costal cartilage to the crest of the ilium. No adhesions were found and a hard mass, simulating a retroperitoneal sarcoma, was felt. Prolonging the incision to the iliac region, the appendix was found sloughed off at the end and penetrating this large mass. It seemed then that the diagnosis of a retroperitoneal sarcoma was correct. Knowing the uselessness of attempting to remove such a tumor on the one hand, and the advisability of establishing a positive diagnosis on the other, it was determined to explore the nature of the tumor. An incision revealed a wall, thickened to the extent of three-quarters of an inch, leading to a large abscess cavity. The introduction of the finger within the cavity led to a point where the appendix was adherent to the abscess, having caused a retroperitoneal abscess, which grew to an enormous size, developing thickened walls, and subsequently simulating a retroperitoneal sarcoma. The pus was examined and was found to be free from living organisms, though still containing streptococci and staphylococci that had not undergone disintegration. This would explain the comparative freedom from inflammatory symptoms in the patient. The abscess was thoroughly drained, scraped, washed and packed with iodoform gauze. From this case we should be reminded of the uncertainties of a positive diagnosis in abdominal tumors, and should, whenever practicable, give the patient the benefit of a positive opinion, which can only be gotten, without disadvantage, by exploratory incision under modern aseptic precautions.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker, and A. J. Ochsner.

Case 3.—A young man, Italian laborer, aged 25, had been convalescent from typhoid fever, and suffered obscure pains in the right hypochondriac region, slight jaundice, but no elevation of temperature. He had often heard of appendicitis, and was convinced, though he spoke very little English, that he was suffering with this condition, explaining that he was assured of this fact. His symptoms were decidedly limited to the region of the gall-bladder. There was slight induration in the right iliac region and constipation. Owing to the persistent jaundice and the pain, a diagnosis of possible gallstones was made, and an exploratory incision was resorted to, over the gall-bladder. This was found somewhat enlarged and containing pus, a cholecystostomy having been performed. While we had made a diagnosis of cholecystitis, and had said nothing about removing the appendix, the patient made us promise that we would explore the region of his appendix. To this we consented. We accordingly made an exploratory incision in this region, and to my great surprise the real seat of his disease was found. The appendix was gangrenous and pus had formed about it. Considerable peritonitis existed, which, if not checked, would have ended fatally. The parts were carefully cleansed, the appendix resected, and both cholecystitis and appendicitis were removed at the same operation. It has often been suggested of late that there may be an intimate connection between the etiology of some forms of these conditions. This case presented a history of typhoid fever, as well as grippe, leaving the system in a reduced condition, unresistant to the invasion of certain organisms and predisposed to the development of metastatic abscesses. There is no wonder that two organs so similarly constructed, histologically, as the gall-bladder and the appendix, should become a prey to the development of organisms from similar causes. Both are connected directly with the intestinal tract, by continuity, only the gall-bladder connecting with the gut from a greater distance and at a point where ferments and organisms have not yet attained great virulence, while the appendix connecting with the gut at a point where practically the intestinal contents have fully served their nutrient purposes, and have become foul refuse matter ready to enter into the colon as a reservoir. This would explain, in a measure, the greater frequency of the infection of the appendix from the gut than the gall-bladder, but if we presuppose a very much depressed condition of the system where phagocytes are weak and insufficient in number, it does not matter so much whether the organ invaded be the gall-bladder or the appendix, whether the organism of infection be from the duodenum or the ileo-cecal region, both gall-bladder and appendix are weak and receptive, the whole system being also depressed, germs may be of uniform virulence the whole length of the intestinal tract, and would tend, therefore, to produce an inflammation of the same character in the gall-bladder at the origin and in the appendix at the end of the small intestine.

Case 4.—A man, Italian, aged 40, was admitted to the Medico-Chirurgical Hospital, suffering with symptoms of chronic intestinal obstruction. There had been gradually more and more difficulty in obtaining evacuations in spite of purgation. A distinct tumor was felt, movable, within an area of 3 inches radius around the umbilicus. There was no fever and pulse was rapid, though strong. The gastro-intestinal irritation and symptoms of dyspepsia suggested the possibility of a floating kidney, though it was impossible to return the tumor to the region of the kidney. An exploratory incision was determined upon, and I must acknowledge that I scarcely had any other condition in mind, as a possible explanation of the symptoms, than carcinoma of omentum or intestine, or floating kidney. On opening the abdominal cavity a large kidney-shaped tumor was found, directly under the umbilicus, consisting of omentum, ileum, colon and mesentery. This mass had formed no adhesions with the peritoneum, but was freely movable, as had been discovered on clinical examination. As the tumor was unraveled and dissected out, a foul abscess was opened, the omentum was resected, the ileum separated from the colon, and an appendix about the size of a thumb was found, having become gangrenous from a perforating fecal concretion. There had been a loosening of the caput coli from the ileo-cecal region, an adhesion to the omentum, which probably drew the parts up to the umbilicus, and a chronic appendicitis had developed away from the normal location of the organ. The appendix was resected, the gut scraped thoroughly with a curette, washed with a bichlorid solution of 1 to 1000 and a gauze sponge introduced so as not to allow the rest of the abnormal cavity to become irritated. The ileo-cecal portion of the intestine was pulled back to its normal position and fastened there to the abdominal wall, while the seat of the inflammation was thoroughly packed with iodoform gauze. Here again, owing to the limitation of the infection, granulations immediately set in and the patient recovered without any further complication. This was another instance of the difficulty of making a positive diagnosis. As I can now retrace the course of the affection, I would venture to say that the adhesion of the omentum to the cecum took place first as a result of the inflammation, there being no other adhesions, the violent contraction and thickening of the omentum gradually lifted up the ileum and cecum to its new position near the umbilicus. In this instance, owing to a lack of adhesions between the inflamed parts and the parietal peritoneum, there was no induration of the abdominal wall, which would lead us to locate an inflammatory condition immediately under it, showing a marked contrast from Case 1, where the inflamed parts were found directly under the indurated portion of the abdominal wall.

It is generally agreed that appendicitis, as such, does not kill, but the peritonitis, incident to the appendicitis, is what proves fatal. The dreaded complication of this widespread affection, therefore, is peritonitis, and he who successfully meets the complicating peritonitis would prove most successful in the treatment of this condition. It behooves us, therefore, to thoroughly understand what we are attempting to achieve before saying that we have succeeded or we have failed in arresting the peritonitis, incident to appendicitis. Therefore, in every case of appendicitis, three different periods should be established:

1. The period of appendicitis, properly so-called; by that I mean such pathological conditions and symptoms resulting therefrom, as are limited to disease, as yet existing in the appendix proper.

2. The stage of peritonitis, resulting therefrom, is limited to a primarily acute or primarily chronic inflammation of the peritoneum, starting from the region of the appendix and spreading thereafter.

3. The stage of septicemia, which means a septic condition of the blood, resulting from poison developing therein, which poison was absorbed from an infectious appendiceal peritonitis.

These three propositions being clearly established, we will say, that for the first, that is, when the inflammation is strictly limited to the appendix proper, the curative measures are medical, when at first successful; operative, when the first medical attempts at relief have failed.

The second condition is the one generally found in its mildest expression, when small adhesions are found about the appendix, and in its most marked expression when an acute abscess, circumscribed or very lately perforated, exists. In this class of cases, while there is a peritonitis, chronic or acute, according to the particular conditions present, the peritonitis is a peritonitis, no more or less, that is, an inflammation of the peritoneum, a condition corresponding to a circumscribed abscess when the condition is chronic, or else if the abscess has broken and has started a general peritonitis, a condition corresponding to a recent perforating gunshot wound of the intestine or a recent perforating ulcer of the stomach or a recent perforating Peyer's patch in typhoid fever. Just as these varying conditions warrant an early operative course to be of a successful issue, so also in these forms of peritonitis from a chronic appendiceal abscess that has perforated or an acute peritonitis set up by the appendicitis, we may hope for success by applying the same principles of rapid operative procedure before the infection becomes generalized and rises from a mere peritonitis to one of septicemia. Upon the treatment of this stage of the condition little need be said. Carefully cleansing the operative field, flushing the abdominal cavity, or if the abscess has partaken of a chronic character, carefully packing with iodoform gauze, so as to isolate the rest of the abdominal cavity, meet the indication and give success.

Not so, however, when we consider the third and most important division of our subject. When the spread of the peritonitis has been such as to have started a septicemia, and both peritonitis and septicemia have joined hands to destroy the patient, what is best to be done? Usually, we simply wash out the abdominal cavity, close to the abdomen, drain with gauze and tube from the most dependent portion and let the infectious elements of the abdomen still develop, furnishing more food for the septicemia that has already started. Shall we continue for a period our attempts at utter destruction of the local peritonitis or local peritoneal infection, preventing further toxins from being absorbed into the general economy, and hoping thereby that the septicemia already set up will be taken care of and destroyed by the still powerful phagocytes? It strikes me that the indication is clear that we must take it for granted that the phagocytes will compete more successfully with a slight amount of septicemia, the sources of which will be shut off, than with a septicemia which is continually increasing by constantly forming toxins taken up from the peritonitis. It would be vain to hope that any form of local peritoneal treatment should destroy the septicemia existing to an utmost degree in the general economy, but it is not vain to hope that local treatment may stop a peritonitis, which, though it be accompanied by the beginning of a septicemia, would ultimately produce a septicemia beyond the control of phagocytic action. Therefore, in the treatment of peritonitis, the two elements to consider are the peritonitis as such and the accompanying amount of septicemia that it has already caused.

This local treatment of peritonitis, whereby the arrest of a progressive septicemia may be hoped for, should consist, I believe, in a constant and persistent flushing of the peritoneal cavity, for at least a few hours after the operation. This should be done, as I described nearly two years ago, by continuous irrigation of the peritoneal cavity with a normal saline solution. It should be applied during the operation at the temperature of 100 Fahrenheit, and maintained after the operation by a system of irrigation, as follows: A glass tube is introduced to the bottom of the pelvis, which is connected with a rubber tube, leading to a basin under the bed. A small tube is introduced at the superior extremity of the wound and is placed in connection with the irrigating apparatus, which latter should be only a few inches higher than the patient. The wound is closed tightly between the two tubes. A continuous irrigation will follow and should be kept up according to the necessities of the case. The immediate effects will be stimulation of the heart action, a general irritation of the peritoneum, promoting phagocytosis, a restraining effect upon the development of local organisms, and a dissolving of the toxins, and draining them away from the abdominal cavity. This, I say, is the direct application of the peritoneum to the principle we have found in general surgery so effective. The indications are the same, just as in general surgery, these local irrigations, though indicated, can not cure the septicemia that has already resulted from an infected limb; so also in a peritonitis, this irrigation can not cure the marked septicemia that has already started, but, just as in an infected limb, this continuous irrigation will restrain the development of organisms, which might otherwise result in a general septicemia; so also the general peritonitis, the continuous irrigation will restrain the development of micro-organisms, which otherwise would intensify the septicemia, rendering it beyond the control of the body. While this method is strictly based on surgical principles, it must not be expected to exert directly more than a local action upon the peritoneum, destroying the source of infection therefrom. Latterly, saline venous transfusions have been strongly advocated in the treatment of general septicemia. Inasmuch as absorption is very free from the peritoneal cavity, we would be warranted to expect even some general benefit from the continuous peritoneal irrigation. However, the important point to remember is not to discredit the beneficial action of irrigations, on account of its failure to destroy septicemia when it has already invaded the general economy. It would be uninteresting to relate the several cases that I have successfully treated by this method. We are justified, I believe, in concluding that, owing to the general acute nature of the peritonitis, the cases would have progressed otherwise to a fatal termination. In one instance the irrigations were kept up for three days; this, however, is not absolutely necessary, as the formation of fibrin from the irritation of the salt solution may impede the dissemination of the irrigating fluid before this time. At all events, the irrigation should be kept up as long as the fluid freely drains from the abdominal cavity. The essential precaution to be taken is that the flow of fluid be free and continuous, otherwise a hydrostatic pressure is produced within the abdominal cavity, tending to impair, mechanically, the function of the diaphragm in respiration. The hopelessness of many of these cases surely warrants a faithful trial of the above method.

THE KNOT WITHIN THE LUMEN IN INTESTINAL SURGERY;

WITH REPORT OF NINETEEN CASES.*

F. GREGORY CONNELL, M.D.
CHICAGO.

The history of the location of the knot in intestinal surgery might be said to be the history of that branch of surgery itself, for, it would appear, that everything has hinged on the knot and its location. When this was outside of the abdominal wall intestinal surgery was in its infancy. The methods were crude, and the mortality high. As the knot began to make its way inward this branch of surgery advanced as a science. Crudity was replaced by a more perfect technic, and, as a result, the mortality rate was greatly reduced. Literally, the involution of the knot might be looked upon as the evolution of enterorrhaphy.

A brief glance at the various steps may not be out of order. It confirms the above and shows that the trend of surgical thought from the earliest times to the present has been a search for the best location for the knot.

In this quest there was a gradual progression from without inward. This may be divided into five stages, as follows:

1. outside of abdominal wall, artificial anus; 2, outside of the intestinal wall, anchored to the abdominal wall; 3, outside of the intestinal wall, in the free peritoneal cavity; 4, outside the intestinal wall, buried between the opposed serous surfaces, and 5, inside of the intestinal wall, on the mucosa.

Attempts to place the knot within the lumen have been made by Vesein, Bishop, Maunsell, Ullman, Cheatle and Hartigan. Breidenbach's suture has been described as "tying the knot on the inside of the lumen of the bowel." Correctly speaking, the knot is not in the lumen, but between the two inverted and coapted margins. It, therefore, cannot be properly included in this list. Czerny and Wölfler merely add a mucous stitch to the ordinary Lembert.

Maunsell was the first to introduce a suture in such a manner that the knots of all the stitches employed in the enterorrhaphy proper, were within the lumen. But this he accomplished by making a secondary longitudinal incision, which he closed with Lembert stitches.

The method here presented, where the knots of all the stitches are within the lumen, was first employed by the author in October, 1898. The possibility of placing all the knots within the lumen in enterorrhaphy is no longer in doubt, but the advisability of such a procedure is still a disputed question with those who never used it.

The chief objection raised to such a location of the knot, is that it necessitates the perforation of all coats of the bowel wall. But the perforation of all coats when the knot is placed within the lumen, and the perforation of all coats when the knot is in the peritoneal cavity, are not the same. These two conditions differ so widely in practice that they cannot be placed in the same class.

It may be admitted that in both cases a communication is established between the lumen and the serous coat of the bowel wall, with the resultant possible danger of leakage followed by peritonitis, either general or local, depending upon the virulence or quantity of the infective material and the natural resistant power of the peritoneum. However, we are led to believe that even with the knot on the serosa, this danger must be small, as the instances where the needle penetrates into the lumen while endeavoring to take a Lembert stitch must be numerous. The fact that the danger is not great can be seen from the results by T. H. Manley following the method of M. E. Connell.

Yet this danger, no matter how small, can and should be reduced materially by reversing the stitch. Then it will be inserted so that the knot is within the lumen, leaving but little, if any, of the loop on the peritoneal surface. By this simple reversal, the danger of infecting the peritoneum by using a stitch that perforates all coats, is reduced to a minimum and is practically removed.

In support of this position we point to the results obtained by original experimentation, and the nineteen cases on the human being herewith reported, as well as the cases of Maunsell and his followers.

With the knot on the serosa, there are present the following conditions: 1. The major portion of the stitch, the knot and ends, is in the free peritoneal cavity. 2. The size of this portion, the knot and ends, prevents perfect apposition of the serous surfaces external to the knot. 3. The drain, the suture material, is broken on the serous coat at the cut ends, so that if capillary action does convey infective material through the wall, it may siphon from the cut ends on to the peritoneum.

On the other hand, with the knot and ends in the lumen, and the loop perforating the serous coats, the conditions are exactly the opposite. They are in this case as follows: 1. The major portion of the stitch, the knot and ends, is on the mucosa, not in the free peritoneal cavity. 2. A small portion only of the loop can be in the free peritoneal cavity, and, if the square stitch is used, a much smaller portion is there than if the circular one is employed. This almost microscopic portion of suture material which passes directly through the two apposed serous surfaces, allows of ample sero-serous apposition distal to it. Thus it is isolated entirely from the free peritoneal cavity. 3. That portion of the stitch between the serosæ of the apposed bowel walls is continuous, not broken, at this point. The natural tendency will then be for the infective material, if it ascends, to pass along the path of least resistance, i.e., from the knot and ends on the mucosa, along the suture material, through all coats of the apposed walls and back again to the knot on the mucosa, there being no knot on the serosa to check and spread it. As Dr. Ferguson[1] has tersely expressed it: "All the knots being on the internal aspect of the bowel, it takes very little sero-lymph to seal up the peritoneal surface, and any drainage that takes place along the suture from the mucosa towards the peritoneum, will be at once returned by capillary attraction to the inside of the bowel." (See Fig. 5.)

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker, and A. J. Ochsner.

From these conditions it may be concluded that the ideal location for the knot is outside and not inside of the peritoneal cavity. As it is impracticable to place it outside of the abdominal wall, it is located in the lumen of the canal, which is still outside of the peritoneal cavity.

Deductions from the above would indicate that stitches which perforate all coats of the bowel wall should be knotted in the lumen. And, conversely, a stitch which is knotted on the serosa should not communicate with the lumen.

That brings up the questions: Is it possible to introduce a firm intestinal suture without communicating with the lumen; and again, if possible, is it practicable?

It is now generally conceded that an intestinal suture to be reliable must include some part of the submucous layer, the one coat of the intestine which has textile strength, and which offers more resistance than will the muscular coats and the serous coat combined. In order to properly introduce an intestinal suture which is knotted on the serosa, the stitch must *penetrate* but *not perforate* the submucous coat. Penetrate to prevent yielding, for "a stitch that includes only the two outer coats yields like putty." But it must not perforate, to prevent infection by capillarity, for, "if the submucosa is perforated the intestine is almost certainly entered."

On the other hand, if all coats are included, and the knot is located in the lumen, no attempt to split the submucosa is necessary.

Halsted,[2] in speaking of this coat, said:

> It is remarkable that no one has recognized the important part which this coat should play in operations for intestinal suture. It is still more remarkable that surgeons could have altogether overlooked the existence of the submucosa. And, it is perhaps most remarkable that experimenters and writers should without exception believe that it is possible to take a stitch of the peritoneal coat alone. The crude views of Jobert and Lembert, as to the construction of the wall of the intestine, have been universally accepted by surgeons up to the present time. The peritoneal coat is believed to be thick enough, and sufficiently strong to hold a stitch, and the existence of the submucous coat has been ignored.

Kelly[3] calls attention to this as follows:

> Regarding the fibrous coat of the intestine, the most valuable contribution which has yet been made to intestinal surgery is the demonstration by Dr. Halsted, of the fact that the essential feature in any suturing or anastomotic operation is the employment of the submucous intestinal coat.

It may not be out of place to call attention to what appears to be an error that has gained wide circulation. That it was unintentional is not to be doubted, nevertheless it is remarkable that two acknowledged authorities should entirely overlook the researches, experiments, observations and conclusions of a man who might be called the father of American surgery. For it is evident that they are not familiar with that classic on intestinal surgery, published in 1843 by S. D. Gross, then of Louisville, Ky., who made observations on this same coat, as will be seen in his monograph entitled, "An Experimental and Critical Inquiry into the Nature and Treatment of Wounds of the Intestine."

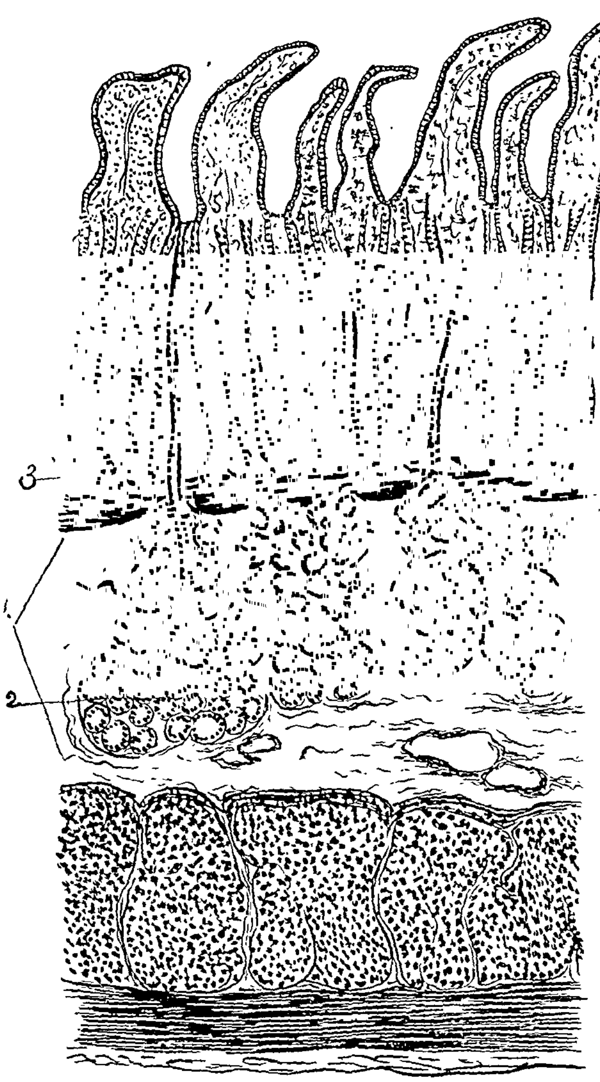

Fig. A.—Section of duodenum (after Piersol). 1. Submucous coat. 2. Glands of Brunner. 3. Duct of gland.

On the structure of the alimentary canal, while speaking of the "outer membrane," he says: "Hence, if, in sewing up a wounded intestine, the ligature be merely carried through the serous investment, it will be almost certain to be torn out." And further, after speaking of the "muscular tunic," he says: "Lying beneath this muscular plane is the celebrated *nervous tunic*, as it was called by the *ancient* writers. Alternately admitted by some, and rejected by others, this layer has been recently described by Monsieur Cruveilhier, under the name of the *fibrous lamella*, in consideration of its structure, which closely assimilates itself to that class of tissues. . . . Strong and resisting, it is semi-transparent and devoid of elasticity. . . . The filaments, of which it consists, interlace with each other in every conceivable manner, forming thus a very close network. . . . It readily reunites when divided, as *I have witnessed in numerous experiments,* and deserves to be attentively studied, *as it is the membrane through which the surgeon should always carry his needle in sewing up wounds of the intestine.*" (Italics are ours.) Thus proving that he not only knew the anatomical peculiarities and properties of this layer, but that at this early date, 1843, he also realized the importance of this layer from an operative standpoint, and emphasized its surgical significance.

---

[1] Chicago Med. Rec., December, 1900.

[2] Johns Hopkins Hospital Bulletin, 1891.

[3] Operative Gynecology, vol. ii, p. 50.

In considering the first question above proposed we should bear in mind the location of Brunner's glands.

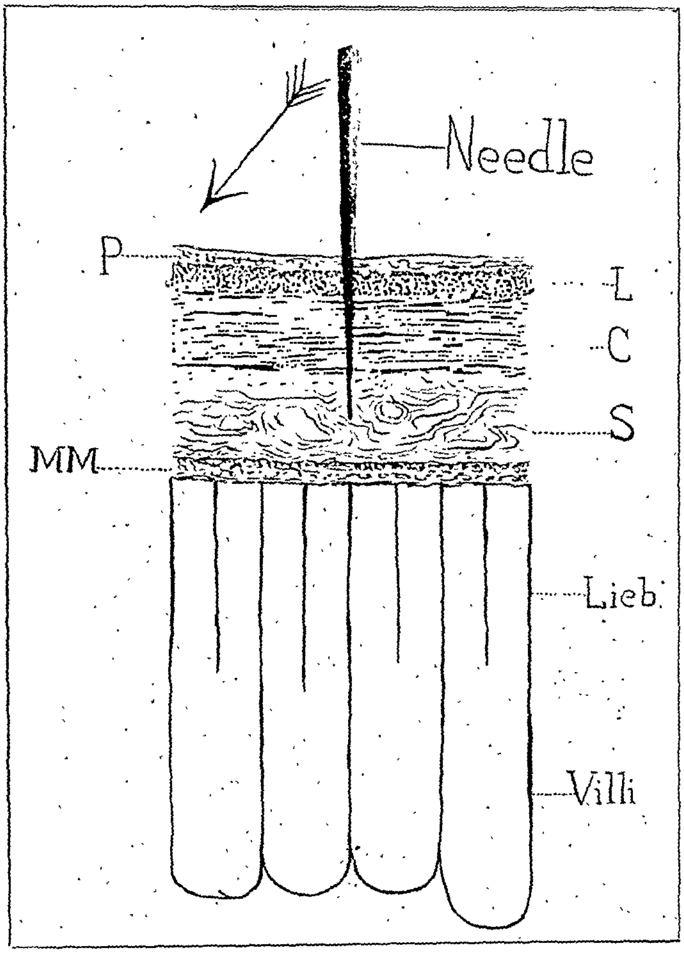

Fig. B.—P, Peritoneum; L, Longitudinal muscle; C, Circular muscle; S, Submucosa; MM, Muscularis mucosa; Lieb, Glands of Lieb. Reproduction of Dr. Halsted's illustration in J. H. H. B., 1891.

These are small, long and sometimes compound, lined with columnar epithelium, the duct of which opens upon the mucosa. These glands are peculiar, in that they are confined to the duodenum, and that the fundus is located in the submucosa. (Fig. A.)

If a stitch enters the serosa of the duodenum, and includes a part of the submucous layer, there is no certainty that it does not pass through one or more of these glands of Brunner. Should this occur the result will be a stitch which penetrates the submucosa, yet communicating with the lumen and knotted on the serosa. Of course, each and every stitch put into the submucosa of the duodenum may not involve the fundus of a Brunner gland. But, not knowing their exact situation, they can not be intentionally avoided. Then as this danger—communication with the lumen—can not be purposely excluded, it is an unsafe procedure to insert in the duodenum stitches which include the submucosa and are knotted on the serosa.

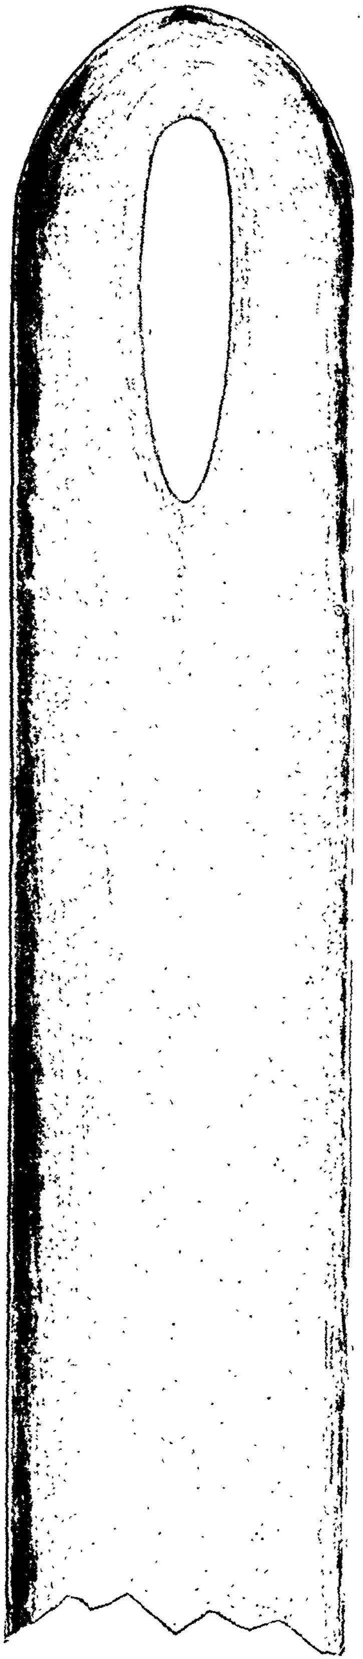

Fig. C.—Ordinary intestinal needle (No. 8), enlarged an equal number of times as is the intestine in Fig. B.

Similarly unsafe, on account of yielding, are stitches which do not include the submucosa. To diminish the first danger—capillarity — and eliminate the second—that of yielding — stitches are used which include all coats and are knotted in the lumen. This will, of course, apply to the operations of pyloroplasty, pylorectomy and gastro-duodenostomy.

Then, to the question—is it possible to introduce a reliable intestinal suture without communicating with the lumen?—the answer must be in the negative, as far as the duodenum is concerned. In the remainder of the intestinal tract there is no objection to the stitch including but a portion of the submucosa, if that be feasible.

Halsted, in his remarks on the importance of the submucous layer, also dwelt upon the fact that for years eminent men had described the Lembert stitch as including but the peritoneal coat. This, he concluded, was impossible, owing to its extreme thinness. The extreme thinness of the submucosa, which is but ten times as thick as the peritoneum (Edmund and Ballance), in turn leads us to doubt the practicability of including but a portion of this coat in a stitch.

In Dr. Halsted's original article is found a detailed description of the technic employed, which enables one to insert the needle in such a manner that the submucosa is "penetrated, but not perforated."

To elucidate this feat is presented a schematic drawing of the intestinal wall, showing the relative thickness of the various layers, with the needle in the act of picking up a part of the submucosa without going through it. The intestinal wall in this drawing is magnified about 32 times, but the artist neglected to magnify the needle. It thus conveys to the observer an erroneous conception as to the relative proportion between the ordinary intestinal needle and the submucosa.

Figure B is a reproduction of the illustration in Dr. Halsted's article. Figure C represents a No. 8 round sewing needle magnified in diameter an equal number of times as is the intestinal wall of Halsted, and which, if represented at full length, would extend 48 inches, and at its greatest width would be four-fifths of an inch. A comparison of these drawings will give an idea of the difficulty one may anticipate in endeavoring to pick up with a needle that is one-fortieth of an inch in diameter but a part of the submucosa, which, according to Edmunds and Ballance, is 1-250 of an inch thick. There is a proportion of 6 to 1 in favor of the needle.

Finally, in answer to the question as to the possibility of introducing a proper intestinal suture without entering into the lumen, we say that in locations other than the duodenum it may be possible for the most expert, but for the average surgeon such an attempt seems impracticable. Therefore, realizing the importance of the submucous coat, the difficulty of splitting its fibers, and the danger of yielding, on the one hand, if it is not included, and that of capillarity, on the other, if it is perforated, we choose between evils. We decide to run the greatly reduced risk of capillarity, in order to positively exclude yielding with its 25 per cent. mortality, by recommending a suture which includes all coats and is tied on the mucosa. One which can be placed with certainty, and one in which the submucosa is secured in every stitch.

The historical progression of the intestinal suture, with reference to the structures included within the stitch, shows also five stages concomitant with the involution of the knot. They are as follows:

1, the suture including all coats, the knot on the serosa; 2, the suture including peritoneum only; 3, the suture including peritoneum and muscularis; 4, the suture including peritoneum, muscularis and submucosa, and, 5, the suture including all coats; knot in the lumen.

ADVANTAGES.

The chief advantages to be derived by penetrating all coats of the intestinal wall and placing the knots within the lumen are: 1. Less danger of peritonitis, through leakage at stitch hole. 2. No yielding of stitch. And among the other commendable points may also be mentioned: 3. Adhesions diminished. 4. Small diaphragm. 5. Less danger of gangrene. 6. No foreign body; suture material will all pass away. 7. Time decreased.

Leakage.—Clumski, in a recent contribution on the subject of intestinal union, states that in all cases of union by suture alone in which leakage occurred, the seat of the leakage was at the site of the knot.

Yielding.—If the submucous coat is not included in the stitch, yielding is liable to take place. In an effort to avoid penetrating into the lumen, when introducing the ordinary Lembert stitch, one is apt to be overcautious and so fail to include any portion of this layer. That yielding of stitches, from this or other causes, is one of the most frequent factors in failure of enterorrhaphy can be seen from the statistics of Rosenthal, who, in 1892, collected 151 cases of intestinal resection followed by end-to-end union, with a mortality of 42.3 per cent., and 50 per cent. of this rate due to peritonitis. He is reported in the translation by Harris as follows: "The frequency of peritonitis was owing to the escape of feces into the peritoneal cavity, due to the inefficiency of the suture or to fecal accumulation. That perforation peritonitis claimed the most victims is a striking proof of the inefficiency of the present methods of intestinal suture." With a single row of stitches which include all coats instead of two or more rows, each including but a portion of the intestinal wall, the danger of yielding, because of not including the submucosa, is positively excluded.

Adhesions.—Concerning adhesion following an intestinal suture, Halsted says: "The success of any form of intestinal suture is inversely proportionate to the extent of the adhesions which result from the employment of the particular method." The most active cause of these post-operative adhesions are the bulky knots and ends, which irritate the adjacent organs or tissue coming in contact with the site of the union. Such adhesions are quite common when the ordinary suture is used, less so if the mattress suture is employed for the knot is not so prominent as it is when located on the top of the joint, as in the ordinary stitch, and still less common after the use of the Murphy button, Frank coupler, or methods of union in which the knots are in the lumen. It has been said that these adhesions tend to strengthen the joint if they do not form bands, underneath which a loop of intestine could become strangulated. Even if no such grave result follows their formation they may act as a cause of vague, indefinite or perhaps marked uncomfortableness, tenderness or pain, which may do considerable toward producing a condition of chronic invalidism.

Diaphragm.—Diaphragm formation is an absolutely unavoidable result following any method of union which adheres to the Lembert principle, i. e., sero-serous apposition. But the size of this diaphragm may range from one so small as to be practically insignificant, to one of sufficient size to occlude the bowel lumen and cause obstruction. The variation depends entirely upon the methods of union employed and the care with which the technic is carried out. In methods requiring two or three rows of sutures the lumen of the tube will of necessity be encroached upon to a greater extent than it will be by a method in which but one row of stitches is employed. In examining specimens after performing the Maunsell method a marked projecting ridge is to be seen on the mucous surface, at the site of the longitudinal incision, which is closed with Lembert stitches, while at the site of the circular suture it is located with much more difficulty. That this diaphragm is practically the only form of post-operative stricture, and that stricture due to cicatricial contraction rarely, if ever, occurs, has been well brought out by W. A. Evans. That a broad serous approximation is unnecessary has been emphasized by J. B. Murphy in his statment that, "A line of approximation is as good as half an inch."

Less Danger of Gangrene.—The single row of stitches instead of multiple layers is advantageous in that there is no danger of interfering with the blood supply of the inverted cut ends. This fact is emphasized by Maunsell when he says, "A double line of sutures should never be applied in intestinal surgery. It obstructs the circulation too much, interfering with firm plastic peritonitis, and in some cases causing gangrene of the inverted portion of the gut." And similarly by Senn as follows: "That the second row of sutures in the Czerny-Lembert has often been the cause of gangrene of the inverted margin of the bowel would not be difficult to prove by many postmortem records."

No Foreign Body.—A stitch which penetrates all coats and is knotted on the mucosa will early and invariably pass away. The ordinary intestinal suture including but a portion of the wall and knotted externally, will become encysted and remain as a foreign body or will migrate directly through the intestinal wall into the lumen and pass off with the feces. If it remains encysted, it may give rise to symptoms more or less objectionable, if not dangerous. In this connection Bishop says: "If it is convenient, if not necessary for a stitch to pass away after its mission is completed, it is better that it penetrate all coats of bowel than if it penetrate only peritoneum." Cases are on record in which, at the autopsy six or twelve months after the operation, there has been found the suture, still partially attached to the wall, so liable, especially if continuous, to cause obstruction at any time. In the writer's animal experimentation, the suture had always disappeared in all specimens which were removed after the fourth week. In one instance, on removal of a twenty-one days' specimen when flushing out the canal, the continuous suture, entirely free, came away with the débris.

Since this report was presented, this suture has been employed in ten additional cases.

Time Decreased.—In post-graduate work Dr. E. Reavely, Silverton, Colo., has performed an experimental enterorrhaphy in nine minutes. This time including the opening and closing of the abdomen.

At a meeting of the Chicago Medical Society, December, 1900, at which the first case of enterorrhaphy all knots in the lumen was reported by Dr. F. H. Martin, and 4 others mentioned by Dr. E. W. Andrews, it was suggested in discussion "that we be extremely cautious in reaching conclusions on such a small experience." Since that time the number of cases where such method has been employed has increased to 19. This may be a small number upon which to draw conclusions, but the results are very encouraging, and it is thought that the method is worthy of consideration.

In the 19 cases on the human being there were 4 deaths, due to the following causes:

In No. 4, pylorectomy for carcinoma, death occurred on the day following the operation, from shock. In No. 9, pylorectomy, with removal of the head of the pancreas, and a portion of the liver, the patient died eight days after the operation. An autopsy in the presence of Drs. Ferguson, Ries and Morgan revealed the line of suturing to be intact. In No. 11, circular enterorrhaphy for strangulated hernia, death followed immediately after the operation, as the result of shock. And in No. 19, pylorectomy, for carcinoma, death occurred from shock within twelve hours after the operation. So it may be said that in none of these four cases can the death be attributed to either the method of suturing employed or the manner of applying it.

Animal experimentation in the original work on this method resulted in 100 per cent. of recoveries. It is recorded that experimental work in this method by student practitioners at the Post-Graduate School of Chicago yielded but 3 per cent. of deaths. The inexperience of these men in intestinal surgery should be remembered when considering this mortality rate.

The Maunsell method is imperfect in that all knots are not within the lumen. The secondary longitudinal incision is closed with Lembert stitches, and the invagination of the cut ends is many times difficult, dangerous and time consuming. This method is also objectionable in that a circular-loop stitch is employed, which allows a considerable part of the suture material to remain on the peritoneal side of the bowel, and it may not hold the free cut ends in as proper position as will the square-loop stitch.

In order to do away with these disadvantages of the Maunsell method the suture here presented, with all knots on the mucosa, was devised by the author in October, 1898. The technic is described with the aid of the drawings here presented. (Interrupted suture.)

Figure 1 represents the first or mesenteric stitch in place. It is at this mesenteric portion of the bowel that the greatest difficulty is experienced when making an enterorrhaphy by any method. This is owing to the presence of the mesentery, the blood vessels, and, what is of greatest importance, the V-shaped space left by the separation of the two layers of the peritoneum.

This anatomic formation leaves a longitudinal strip of bowel devoid of serosa, over which the peritoneum must be drawn, before a perfect sero-serous union can be secured. This particular manner of passing the mesenteric stitch can be recommended in any enterorrhaphy regardless of the method which may be chosen to close the remainder of the circumference.

To take this stitch the needle is made to enter, from the lumen, the bowel wall of one cut end, perforate all coats, and pass through the serosa of one side of the triangular space. Then over to and into the serosa of the opposite cut end, at the same relative point—side of the triangular space—then through the wall into the lumen. This completes one-half of the stitch, and is made with one move of the needle. The needle is then reversed, and, at a distance of about one-eighth of an inch, is made to enter the mucosa of the second cut end, pass through all coats of the bowel wall, including the serosa of the triangular space, and then through the serosa of the opposite triangular space of the first cut end, on through the wall into its lumen, where the needle end and the free end of the stitch are tied on the mucosa. This stitch absolutely secures a perfect approximation at this point.

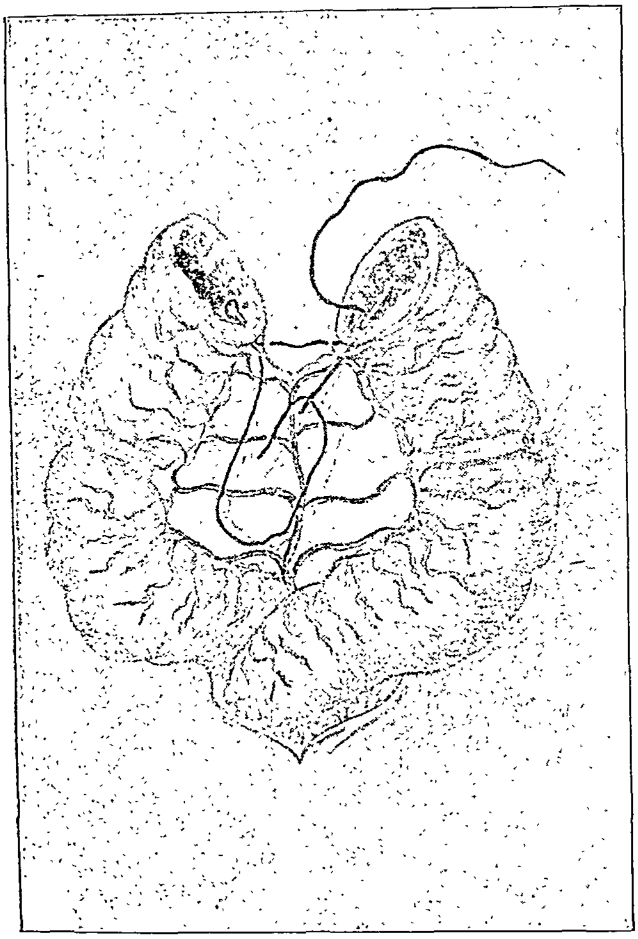

Fig. 1.—Mesenteric stitch.

Figure 2 shows the mesenteric stitch as tied. The ends are not cut off at this point, for they can be utilized as a suspending loop, or guy-threads (No. 1). At a point about one-third of the circumference to the right of the mesenteric attachment a similar stitch is inserted, the ends of which are left long to form a suspending loop or guy-threads (No. 2). This stitch is exactly similar in its placing to the first stitch inserted. The needle begins on the mucosa, goes through mucosa and serosa of the first cut end, then enters the serosa of the second cut end and passes through all coats, then returns at a distance of about one-eighth of an inch, passes through the mucosa and serosa of the second cut end, and on through the serosa and mucosa of the first cut end into the lumen, where the knot is then tied on the mucosa.

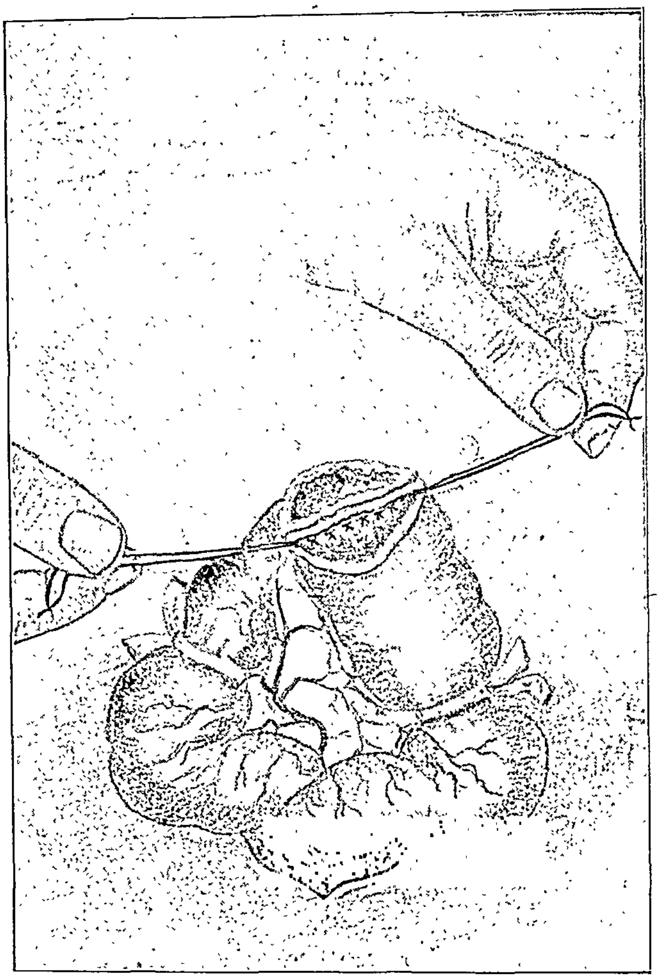

Fig. 2.—First third sutured. End stitches used as guy threads No. 1 and No. 2.

Guy-threads 1 and 2 are held taut, and the coapted walls are secured by the necessary number of stitches, inserted as the one above described. These loops, or guy-threads, consume no time, as after the ends are cut all that remains is a stitch in its proper place. They hold the intervening portion of the bowel circumference in the proper position, that of sero-serous apposition, so that, in making what we term the square stitch, with one movement of the needle, the mucosa and serosa of one side, with the serosa and mucosa of the opposite side are included. A second movement of the needle includes the same coats in an opposite direction, and completes the stitch to the point of knotting on the mucosa.

Instead of the one-third division of the circumference of the bowel it may be divided into halves. But by dividing it into thirds a full two-thirds can be united by this easy to-and-fro movement of the needle, while the apposing cut ends are held in coaptation.

There is, then, but one-third to be closed by the final stitches. These are few in number, but they require more movements, and are, therefore, more difficult and time consuming.

If the circumference be divided into halves only one-half will be united while the parts are in the favorable position. Instead of guys of any description the holder of Dr. E. H. Lee may be used. This is a very efficient aid and can be highly recommended.

This rectangular method of suturing, or the square stitch, is to be preferred to the circular. In using a simple circular stitch, as did Maunsell, there is danger of a resulting infection of the peritoneum, because the margins of the gut wall included in the bite of the stitch are liable to slip and lead to fistula, if nothing worse. Or, infection may travel along the suture material to the free cavity, for the external portion of the stitch is not so completely buried between the apposed surfaces as in the square stitch.

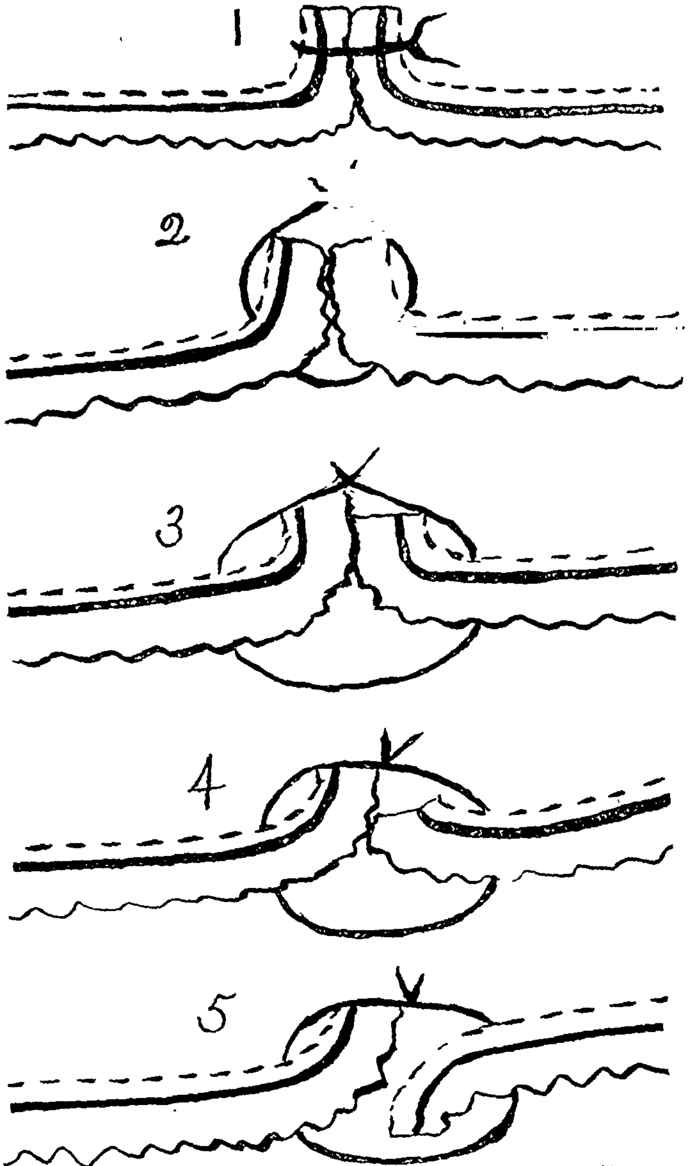

Fig. D.—1. Square stitch, margins can not slip. 2 to 5. Circular stitch, margins can slip.

The possibility of the cut edges slipping by one another when included in the circular-loop stitch is shown in the accompanying cut (Fig. D).

In Figure D, 2 represents the ordinary circular or Maunsell stitch, including within its grasp the inverted margins of the cut ends; 3 shows the relative position which the suture and bowel ends may assume, owing to pressure or distension; 4 illustrates the condition which may follow if more force be applied to one cut end than to the other; and then if, with a slight aggravation of the cause, the pressure increases, one cut edge slips by the opposite cut edge, and a sero-mucous apposition results, as shown in 5, a sinus connecting the lumen of the bowel and the peritoneal cavity, with a fecal fistula as a very favorable outcome. 1 illustrates that, with the square stitch, such an occurrence can not take place.

Guy-thread No. 2 has been removed; that is, the ends which were left long after tying the stitch at that point have been cut away. And at a point one-third of the circumference to the left of the mesentery a stitch is inserted, tied and the ends left long, as guy-thread No. 3. This brings into the proper position for suturing the second one-third of the bowel circumference.

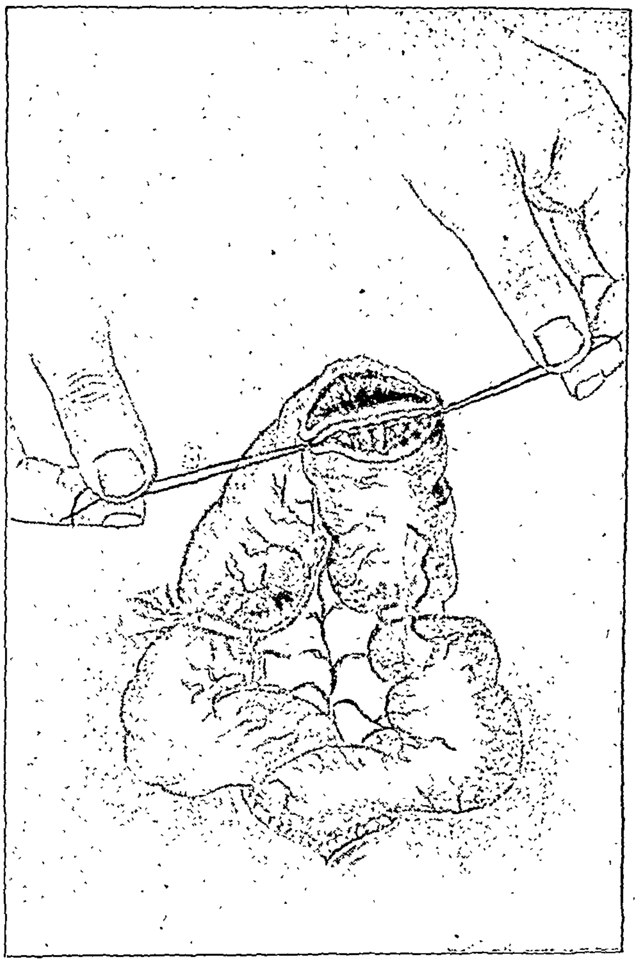

Fig 3.—Second third sutured. Guy threads No. 1 and No. 3.

The guy-threads 1 and 3 are now held taut, and the intervening space sutured, as was the first one-third.

The guy-threads 1 and 3 have been cut away, and the intestine will assume its normal position. It will be observed that at this stage a transverse section of the bowel has been transformed into a wound extending but one-third of the circumference, at the convex border.

The most difficult two-thirds of the enterorrhaphy, the mesenteric, has been completed. The remaining convex third must be closed by sutures exactly similar to those used in the first two-thirds. That is, the needle passing through opposite walls in the following order: Mucosa, muscularis and serosa; serosa, muscularis and mucosa, and this same order repeated in the opposite direction, one-eighth of an inch away. This brings the knot at one side of the union, in the lumen.

Owing to the impossibility of bringing the intestinal walls of this last one-third in the same relative position, that of sero-serous apposition, before the introduction of the stitches, it is necessary to proceed somewhat differently in order to arrive at the same result.

The needle enters the gut wall from the lumen, passes through all coats and emerges from the serosa of one side. It then crosses over to the opposite wound margin and enters the gut wall from the outside; passes through the serosa, the muscularis, then the mucosa and into the lumen. The needle is then turned upon itself and made to retrace its steps at about one-eighth of an inch distant. It passes from the lumen through all coats, emerging on serosa, then over to the opposite side, entering through the serosa, muscularis and the mucosa, into the lumen.

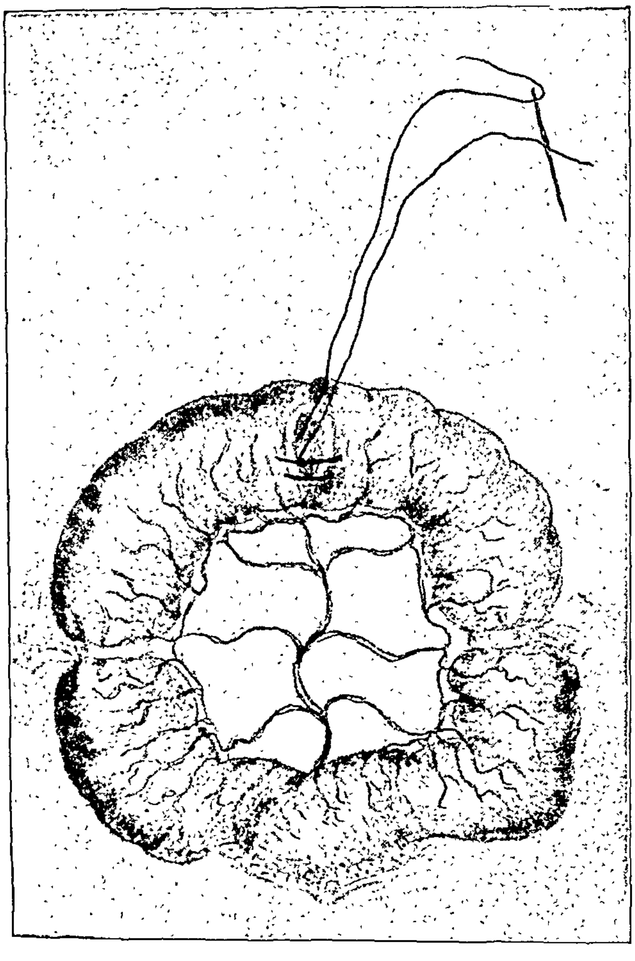

Fig. 4.—Two-thirds completed. First stitch in last third.

Now after drawing this stitch tense and tying it on the mucosa we have, as a result, the same sero-serous apposition as was effected in the first two-thirds. This step is repeated till the last stitch is to be tied.

On account of the small unsutured space remaining it is impossible to tie this last knot on the mucosa in the ordinary way. This last stitch is inserted in the same manner as were the others in this last third, but its two ends emerge from the mucosa, and out of the lumen through the still unclosed portion of the wound, side by side, ready for tying.

At a point in the line of union about opposite this last stitch a threaded needle is inserted, eye-end first, between two of the previously inserted stitches. The needle eye is passed between the apposed serous surfaces into the lumen, and then out again at the place where the last stitch ends still protrude. At this point we find the two threads which, when tied, will form the last knot. The threaded needle is slightly withdrawn and so forms a loop with its thread. Into this loop are placed the ends of the last stitch. Then, by withdrawing the needle, and in its loop the stitch ends, they will present on the peritoneal coat of the opposite side, at the point where the needle was previously inserted.

Slight traction upon these ends will cause the remaining portion of the line of union to become inverted, and sero-serous approximation will obtain entirely around the bowel. On further traction the bowel will become flattened, bringing the mucous membrane, upon which the last knot is to be located, in intimate relationship with the line of suture, at the point where the free ends protrude.

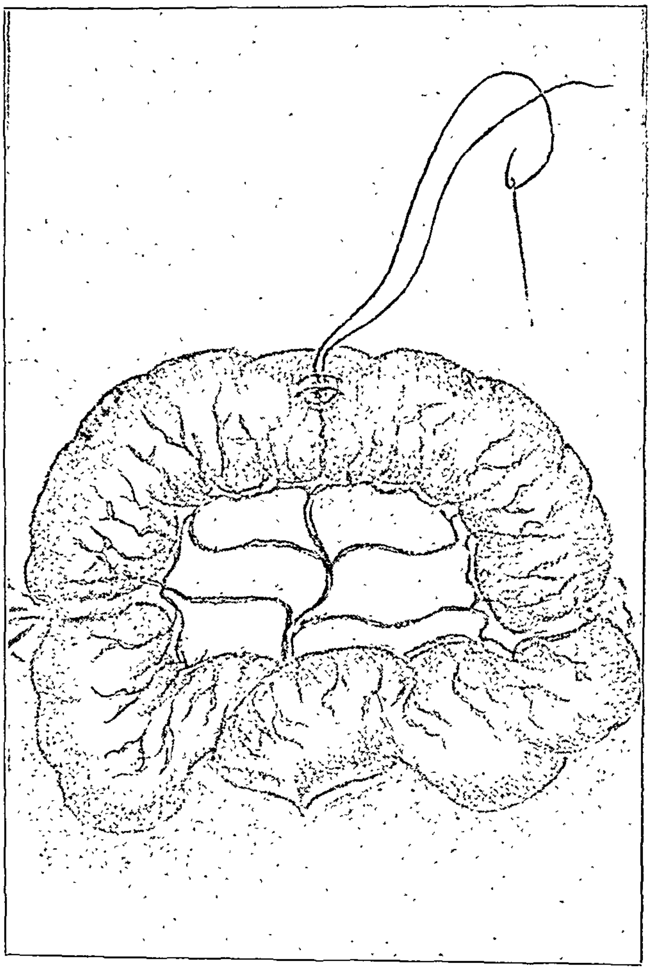

Fig. 5.—Last stitch in last third.

The knot is then tied while the bowel wall is in this position, thus not allowing of any slack. While still retaining the tension and the flattened position the ends of the stitch are cut off short, so preventing the dangling of long free ends in the lumen.

Now, upon allowing the bowel to resume its natural contour, that of a cylinder, the knot will slip, between the already tied stitches, into the lumen. And, as it is fastened to the mucosa of the opposite pole of the diameter, it goes with that portion of the bowel wall.

By this procedure the enterorrhaphy is completed, with all knots on the mucosa. The bowel is then washed with hot normal salt solution and replaced in the abdomen.

The drawings here presented demonstrate the use of the interrupted stitch. This was done, because, in all previous descriptions[4] of this method, the continuous suture was illustrated with a view to the time-saving feature. And also, to demonstrate that either the continuous or interrupted suture may be as satisfactorily employed.

This method may be applied equally well in circular enterrorrhaphy, lateral anastomosis, pylorectomy, pyloroplasty, gastro-enterostomy, and in incised wounds. In fact, under any condition where the ordinary suture may be employed.

CONCLUSIONS.

1. Yielding and leakage are the most frequent causes of failure in enterorrhaphy.

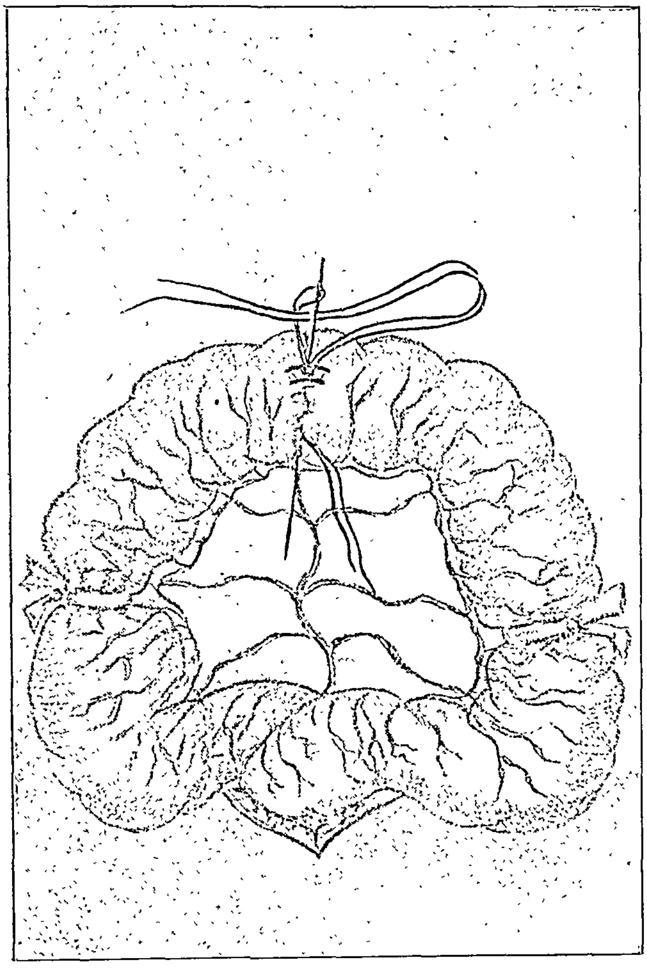

Fig. 6.—Ends of last stitch in loop of threaded needle. Previous to withdrawal.

2. To include all coats of the bowel wall, removes the danger of stitch-yielding.
3. To place the knot within the lumen, diminishes the danger of capillarity.
4. The square-loop stitch is more reliable than the circular-loop stitch of Maunsell.
5. The relative thickness of the needle, and the submucosa, surrounds the procedure of "penetration without perforation" with great uncertainty.
6. To fail to include the submucosa, leaves a weak stitch.
7. To perforate the submucosa is practically to open into the lumen.
8. To penetrate into the submucosa of the duodenum, is practically to perforate the submucosa.
9. It is not only possible, but practical and advantageous, to place all the knots of an enterorrhaphy within the lumen.
10. The ideal location for the knot is outside of the peritoneal cavity.

290 La Salle Avenue.

DISCUSSION ON PAPERS OF DRS. DEAVER, LAPLACE AND CONNELL.

Dr. D. A. K. Steele, Chicago—I am glad that there is one hospital in this country where autopsies can be held after each death, even where there are occasional legal complications attending them, because that is the only way in which scientific surgery can make positive advances. All of us have cases of appendicitis that die, and die unexpectedly sometimes, in which it was impossible to obtain the consent of friends to permit an autopsy, and it places us in the humiliating position of saying, "I do not know why that man died." Dr. Deaver can tell us in all of his cases the "why." I had in my own experience a child of 3 years who was brought to my clinic for the purpose of having an appendectomy done, in the late development of an appendicitis—at the expiration of perhaps a couple of weeks from the time of the pain and tenderness and tumefaction occurred in the region of the appendix, or possibly a little higher, and in which, upon eliciting the history of that child, I learned that the patient had, three months previously, in playing, placed a shawl pin in the mouth and it disappeared. Nothing was heard from it until two weeks before coming into the clinic; pain was located in the appendix, and when the child was brought to me there were the ordinary symptoms of tumefaction, tenderness, temperature and everything to indicate an acute infective appendicitis; but back of this was the history of the disappearance of the shawl pin. Nothing was

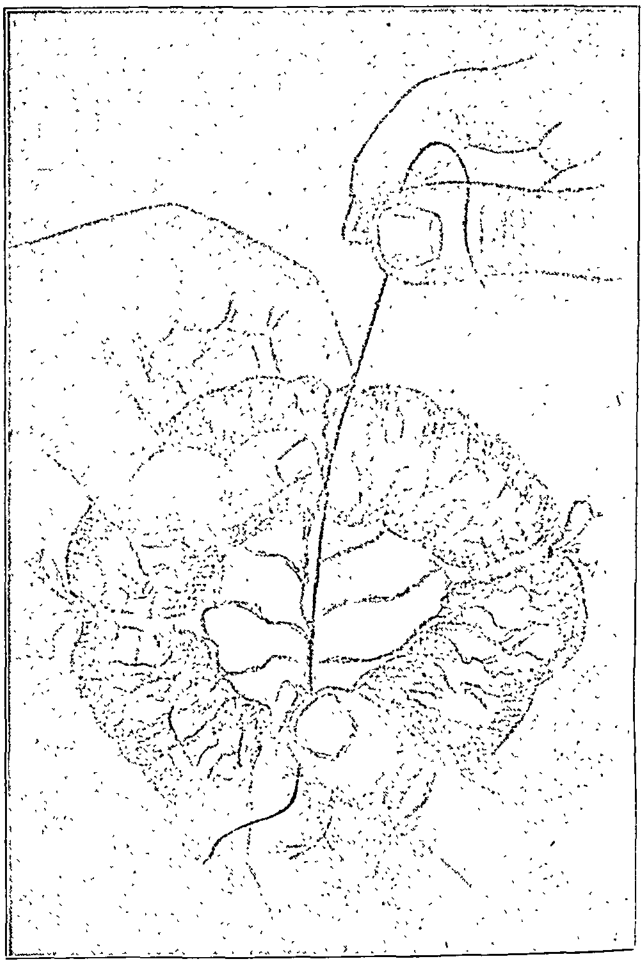

Fig. 7.—Ends of last stitch presenting at opposite side being tied.

---

[4] Connell: Phila. Med. Monthly, January, 1899. F. H. Martin: Journal A. M. A., Nov. 3, 1900. E. H. Lee: Annals of Surgery, Janaury, 1901. Connell: Medicine, April, 1901.

discovered and there was doubt as to whether it was in the intestinal tract. The child was so young that the statement had to be taken with some allowance. This was simply opening an abscess, cutting down, slashing into it, putting my finger down and finding the point of the pin projecting into the inflammatory mass. It was a case of perforation of the intestine from the inner side, the pin projecting and an exudate around it. The disappearance of the shawl pin was marked by the disappearance of all the symptoms. I have had no personal experience with continuous irrigation in cases of septic peritonitis. Dr. LaPlace's method is a good one. When we get such good results from normal salt solution in septic joints, why should not the same idea be extended to the abdomen? If we keep continuous salt solution running through, this is the better procedure than leaving the salt solution in and flushing in an upward direction to secure the disappearance of the microbic organisms through the diaphragm. In regard to the paper by Dr. Connell, it is a masterpiece, the reasons he gives for his method of suture, placing knots in the lumen of the intestine where they are harmless, and the correct approximation. The advantage of this method I have had an opportunity of studying in one of my own cases.

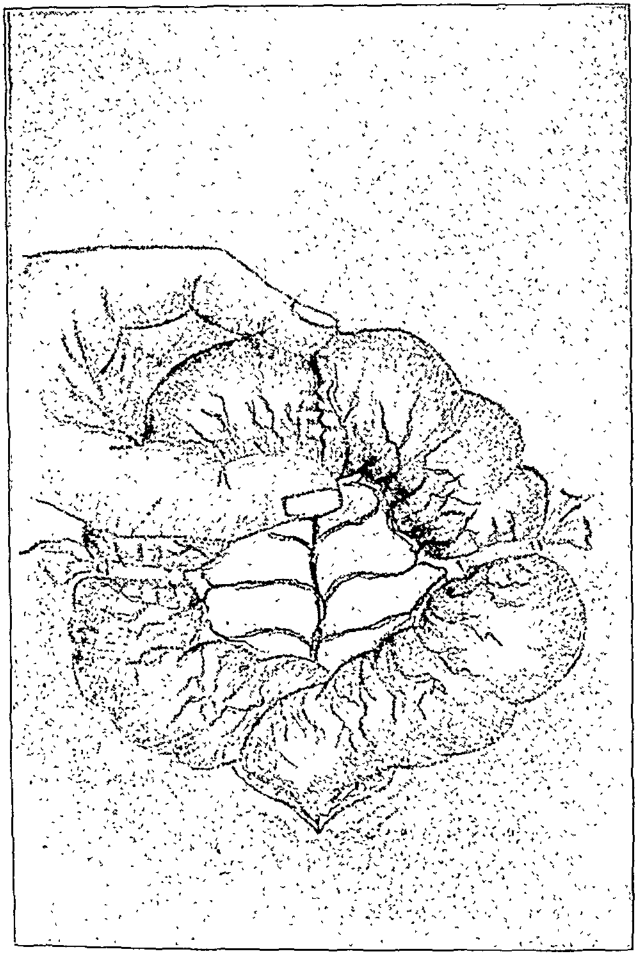

Fig. 8.—Last knot has slipped within the lumen. Enterorrhaphy is complete. All knots on the mucosa.

Dr. J. B. Murphy, Chicago—I was very much interested in the paper of Dr. Deaver, and as Dr. Deaver had to omit some parts of his paper, I will ask him some questions concerning the pathologic conditions, not mentioned therein, on which I fear we are not a unit. I wish not only to concur with Dr. Deaver in this particular paper, but also in many which he has read before on this subject. I think the members of the profession owe Dr. Deaver a debt of gratitude that I fear they will never be able to pay, for the work he has done in this line. In the strong stand which he has taken from the beginning as to the relation of the pathologic conditions, with the procedure necessary for their relief and the time in which that procedure should be instituted, Dr. Deaver has been the great leader. Regarding pathologic conditions, I wish to ask Dr. Deaver just what he means by "suppurative peritonitis."

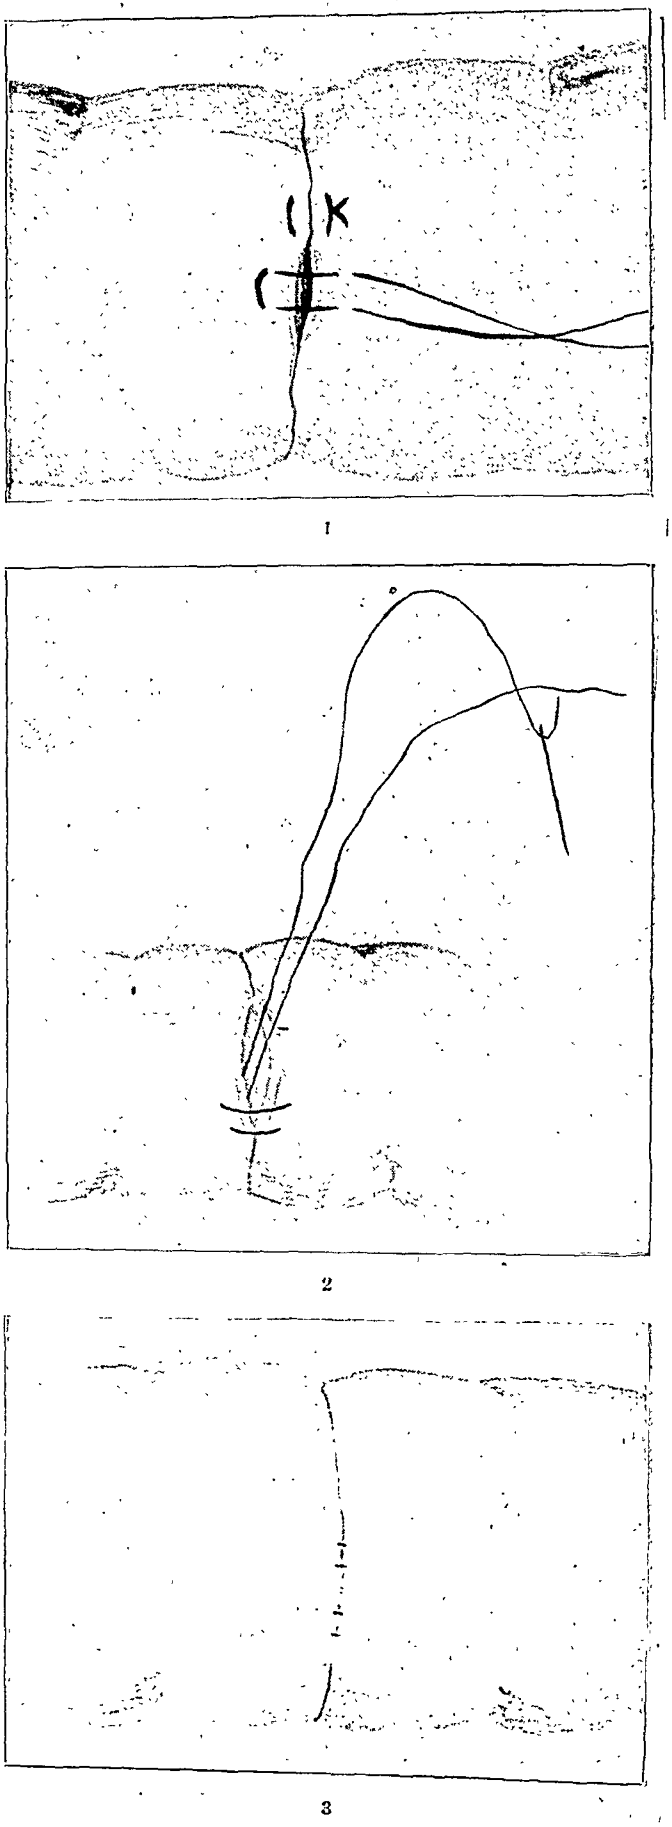

Fig. E.—1. Quilt stitch knot on serosa. 2 and 3. Square stitch knot in lumen.

I am sure that many of the members of this Section who are present do not understand exactly what he means by suppurative peritonitis. I am sure Dr. Deaver does not mean the condition where there is a cream-colored fluid in the peritoneal cavity, with a peritoneum that still retains its luster, for if he did, many men could say, "I have seen many cases of suppurative peritonitis recover." I feel that Dr. Deaver means by an inflammation of the peritoneum that the infection is of the type that invades the serosa. If that is what he means by peritonitis, then I hope we are comparatively a unit; that operations for that type of peritonitis are particularly fatal is known to all. The presence of pus in large or small quantities, with the peritoneum still retaining its gloss, though red and congested, means in this type that the peritoneal surface is not open for absorption of the products any more than an erythematous skin is open to infection. The skin may be congested and the peritoneum congested and still the epithelial and endothelial shingles be intact. If these endothelial cells are intact, I feel that the patient is going to get well, regardless of the quantity of pus in the peritoneal cavity.

There are some other questions that have come to my mind, and I intend to ask the opinion of Dr. Deaver on them, because I am not just satisfied as to what rôle they play. The first is the element of tension in an invaded area. We recognize in general surgery that infection is greatly lessened, the tension is relieved, that is, there is a subsidence of the manifestations of intoxication. Do we relieve all tension by opening the peritoneal cavity and allowing the pus to flow out? Yes, unless the pus is retained in circumscribed pockets. Infection under pressure produces rapid destruction of all tissue by the increased advantage of the biotic and toxic action of the sepsis on tissues depleted by the pressure. The immediate opening and drainage of pus from the peritoneal cavity lessens the liability of destruction of the endothelial cells—the shingles of protection against absorption. Is the drainage always sufficient without irrigation? For my practice I would say, "Yes." The next question is the type of the infection. Do we recognize in peritonitis certain types of infection? Yes. Many times when we open the peritoneal cavity for peritonitis—I mean from the appendix—whether infection occurs through the opening of the wall or through perforation is a matter of indifference if we have the virulent type of infection.

A final question: Is it possible to make a diagnosis of the pathologic conditions within the peritoneal cavity from the symptoms? That is the most vital question from a practical standpoint. I take the stand for myself; I take the stand for our profession; I take the stand for the people, that we can tell from the symptoms neither the extent of the pathologic changes within nor the tendency of these changes. When we assume to do this we put ourselves in the position of judges from the outside, as to whether the pathologic conditions in the peritoneal cavity are going favorably or unfavorably. The greater my experience with acute peritonitis and acute appendicitis, the more certain I am that I am unable to diagnosticate the type and degree from the symptoms and physical signs; the more certain I am that I can not say from the course of appendicitis in the first twenty-four or thirty-six hours, that it will not terminate in that virulent, fulminating appendicitis which every surgeon and practitioner dreads; the more certain I am that I can not say whether it is a staphylococcus, a streptococcus or a virulent type of the bacillus coli communis infection. Many years ago I believed that it was possible for me to say, "This is one type of infection; that is another," but now, with something like 1600 cases of appendicitis operated, I am convinced that it is impossible to say what the type is and what the termination.

When the peritoneal cavity is opened I believe that we can approximately tell from the appearance of the surfaces within, whether the patient will recover. If it is blistered and excoriated to an extensive degree, even with a small quantity of pus, the chances are that the patient will die, drainage or no drainage. While if the peritoneal gloss be retained, no matter what quantity of pus be present, the chances are that the patient will recover with simple drainage. Finally, I feel more strongly the position I took ten or twelve years ago, that all cases of appendicitis are dangerous to life, that in 98 per cent. of cases the infective material is confined within the appendix during the first twenty-four hours, that operative procedures instituted within that time give a mortality of less than 1 per cent., that the percentage of danger from the disease is enormously greater if interference be postponed beyond that period of time, and since my sacred and solemn duty to my patients compels me to treat them by the means which least jeopardizes their lives, therefore—that an operation should be performed within twenty-four hours after the first onset of the symptoms.

Dr. LaPlace's forceps are a matter of no small moment in the technic of enterorraphy. It exactly regulates the degree of inversion of the cutaneous edges of the bowel and gives a firm uniform surface, upon which the suture may be applied. It enables the surgeon to approximate lumens of varying size with an even division of spaces. It can be used for lateral as well as for end-to-end anastomoses. It enables one to control the relative position of the two mesenteric attachments, that is, they are not allowed to come directly opposite each other. When the work is completed the forceps are easily removed and the final stitch placed. Further, it gives assurance that too much of the bowel is not inverted and stenosis will not occur as a sequence of the suture.

Dr. Connell's able presentation of his very ingenious method of suture must attract the attention of every abdominal surgeon. It has in it so many elements that appeal to the thinker on intestinal approximation, and I have found in the use of the suture that his theoretical advantages are sustained in its technical application, as well as the security afforded by it. It gives an exact approximation of the serosa over the entire circumference of the bowel and particularly at the weakest point of all other methods of intestinal approximation, namely, the mesenteric attachment. When the suture is properly applied, and it should never be otherwise, the peritoneal coverings are brought into close contact so as to lessen the liability of leakage at the mesenteric attachment. The suture material is nowhere exposed on the peritoneal side and neither is the final knot. It does not require an additional opening in the bowel as does the Maunsell stitch. The degree of eversion of the edges can be controlled better than with any other, which is an important matter in this work.

The liability of leakage around this suture is very small on account of the manner in which the approximation is produced. The technic of its application is not difficult and I might add that there is no suture of the intestine that can be made without a careful consideration of this method. If suture is to be used at all, I believe that the Connell suture has advantages over any other with which I am conversant. It can be applied to the lateral as well as the end-to-end or the end-to-side. Dr. Connell deserves the sincere thanks of the profession for giving them this accurate method of intestinal approximation.

Dr. E. J. McKnight, Hartford, Conn.—Following in the line of the last speaker, I am a little surprised that nothing has been said about the blood count in cases of appendicitis. In many cases we have in this very positive knowledge. A child 6 years old was taken with vomiting and pain in the abdomen. The case was not considered serious, and when I saw it one week later, at 1 p. m., the vomiting had ceased, the pain had disappeared and there had been several operations of the bowels from salines. The abdomen was distended to some extent, muscles not rigid. There was a case in which I was entirely at sea and relied upon the blood count. There was found to be a leucocytosis of 38,000. I am positive that the methods were accurate. We determined on operating, and the operation was performed at 5 p. m. On opening the abdomen, foul-smelling pus flowed out and the appendix was found to be ruptured and gangrenous; the lower portion of the abdomen was bathed in pus and intestines were congested and red and covered with patches of exudate. The appendix was removed and the abdomen thoroughly flushed, being thoroughly washed out with salt solution, every point of the abdominal cavity being reached with a glass tube connected with an irrigator. The very slight adhesions that were forming were broken up gently and every part of the abdominal cavity was flushed. There had been a recent case of similar nature, in which a small portion at the back of the meso-colon was not reached for some unaccountable reason. This resulted in abscess, and led me to be more thorough in washing. I saw the patient two days after operation and supposed he would die. I received this morning a telegram from my assistant who said that to all appearances the boy was out of danger. Of course, it is too early to say that positively, but in spite of what has been said about not washing out the abdomen, I feel that the thorough flushing of that abdomen, the positive knowledge I possess that every portion of that cavity was thoroughly washed out, leads me to believe that the patient will recover. As regards continuous irrigation, I do not see how that will accomplish much, for after a short time the fluid may only reach a circumscribed space, adhesions will form and only a small portion of your abdominal cavity is flushed. I relate this case mainly to call attention to the positive information to be obtained from the blood count. Another case occurred in January, in which a young man had had repeated attacks since November, not severe, but which confined him to the house and made him an invalid. The operation in this case was performed when the parts were congested and the adhesions vascular, but there was no pus. On the second day the temperature rose to 100.5 and the next day to 103. I feared that we had infection. There was nothing to account for this. The blood count showed a leucocytosis of 8400. This was taken morning and night and remained the same; the temperature continued about 103 for three days. I feared an infection, but relied upon the blood count and waited. The temperature subsided and the patient made a complete recovery. It was due to an attack of grip. In that case if we had not had positive knowledge from the blood count, we should have been obliged to open the wound with the expectation of finding pus.

Dr. T. J. Maxwell, Keokuk, Iowa—I wish to give my voice for irrigation in general peritonitis and septic peritonitis. I read a paper before the Iowa State Society, four years ago, and one before the American Medical Association, at Denver, three years ago, recommending that plan by introducing a tube under the stomach, and another tube—a discharge tube—from the pelvis, and irrigated continually until all the tendencies to rise of temperature had ceased. I have one case to relate, which I think was saved by that method. This case I operated upon for tumor; the tumor burst during anesthesia, discharging the contents through the abdomen. After three days the temperature began to rise, vomiting commenced, the pulse rose to 130, all symptoms of septicemia were present and I instituted irrigation of normal salt solution, and repeated it every four or five hours for three or four days. With the first irrigation the temperature came down, within an hour, from 104.5 to nearly normal, and the temperature was not allowed to rise above 100 F. after that. The appetite returned, vomiting ceased, the bowels were moved and the patient recovered. The general, thorough irrigation of the abdomen is indicated.

Dr. E. W. Andrews, Chicago—The papers of Drs. Deaver, LaPlace and Connell belong to the type of real contributions to surgery and we are very much indebted to them. Now, this question of irrigation. Dr. Murphy has told us that there was the element of the type of the infection. True enough, but there is one other element, which perhaps he might have added, the element of the length of time of the infection. When we are brought to face this question, why not drain or wash out the peritoneal cavity? Let us see the conditions in this one disease of appendicitis, leaving out of the question the disease we heard discussed yesterday. We have a pus focus on one lower side of the abdominal cavity. We drain. A quantity of pus runs out, fetid or quite clear. How do we know what the conditions are when we find free pus in the intestines without a restraining wall? Can any man say that a collection of pus has invaded all parts of the intestine and smeared the surface of every part of the intestines in that patient? Many times around this area of pus is another zone of sero-pus and serum; I have seen that pus first flows as a milky serum, and finally clear serum flows from a wider zone. If that is true—and certainly on the table we have all demonstrated in these cases where there is no wall—what shall we say about the propriety of flushing out the abdominal cavity? Only this, that as sure as this patient recovers it is because there are one hundred square inches of peritoneal surface which have entirely escaped infection, perhaps entirely escaped the contact with fluid. Pus or extravasated matter may lie in contact with the peritoneum a few hours and not cause fatal peritonitis. We see it in gastric ulcers, where we see operations in extravasation cure 80 per cent. of cases in the first operated upon in the first twenty-four hours and 20 per cent. of the cases operated upon later.

What of the possibilities of recovery after leakage into the peritoneum? All cases which recover in so-called septic, generalized peritonitis are cases in which at least a part of the peritoneal cavity has escaped contact and every case in which all surfaces were inflamed dies. What is the bearing of that on the question of flushing out? We fill the peritoneal cavity with water, and by that means disseminate the infection to every remote part of its surface. I say no. I can cite as many cases on the other side as Dr. McKnight has cited here—recovery under simple drainage the moment the pressure is relieved. Out flows the pus and in spite of the demonstrations of Dr. Clark, the current is towards the drain. I have had many more recoveries since I have used the Fowler position; I have used it in four or five cases since the first of January, after operations in which pus was present without adhesions. Under that treatment recoveries have taken place in my practice in a way totally unexpected to me, and in which I have never seen before under any form of treatment.

Dr. Connell's paper has interested me greatly. I see that the paper deals apologetically with the question of perforation of the mucosa. When you scrutinize this question, think of what it means. Does not the world-wide known device, the Murphy button, do the same thing? What do we have there? We have the button in the mucosa, approximating two serous surfaces. Take, for example, what to my mind is the next best suture in enterorraphy—the Maunsell operation. It is a very satisfactory operation, but one in which absolutely the suture passes cleanly through from serosa to mucosa. The Connell suture passes from one side to another, but it does not leave any portion, not even the final knot outside of the peritoneal cavity. Having done both operations a number of times, I have noticed this distinct difference between the Connell final stitch and the Maunsell—with the latter the stitches are distinctly seen after the knots are tied. At every stitch you see a little danger point, the crossing of the silk thread; in the Connell stitch the enfolding of the serosa hides the stitch. Dr. Connell's paper did not describe his operation, and, therefore, to those who are not familiar with it it is exceedingly unsatisfactory. The Connell stitch has this merit, which it has in common with all the best of modern gastric and intestinal work, namely, it is a continuous stitch. I believe the continuous stitch is the secret of success in suture work in the bowels and intestines; more than that, it has precisely the merit of the Murphy button, in that it is practically a clamp. When the Connell suture is put back and forth, through and through, holding these inverted edges together, it is a clamp. Dr. Connell has kindly reported five of my cases. I had his assistance in the first one or two. I had also been taught to do it upon the gloved finger and upon the dog.

Dr. M. L. Harris, Chicago—I wish to say a few words on the point brought out by Dr. Murphy, namely, are we able to diagnose the condition within the abdomen? I say most emphatically that we are not able to diagnose the condition and that many times it is impossible for us to form any conception of the true condition to be found, either within the appendix or within the peritoneum by our present means and methods of diagnosis. The question of leucocytosis, brought out by Dr. McKnight, is unquestionably one of value, but in the cases where we need it most it fails us and is of little diagnostic importance. In the fulminating cases we find that the system, for some reason, is so overwhelmed by the intoxication that leucocytosis absolutely fails. There is no increase in the number of leucocytes, in fact, they may even be diminished. Again, in many of the mild cases which are apparently progressing favorably, so favorably that we may be in doubt as to the best course to pursue, there may be no leucocytosis, still we may open the abdomen and find a large appendix distended with pus on the verge of rupturing, or an ulcer which has extended to the peritoneal surface and would unquestionably perforate in a few hours and produce acute infective peritonitis. In these cases leucocytosis fails us; it has not yet taken place, and it is impossible for any one to determine these conditions before the abdomen is opened. As with Dr. Murphy, I have had three such cases recently. Two of the cases were of a mild type, in which perforation was imminent and in which there was scarcely a symptom, except the mild tenderness to indicate that the patient had an appendicitis. Still, perforation would unquestionably have taken place within a few hours and acute infective peritonitis would have been precipitated. It is impossible to determine before opening the abdomen in many of these cases the conditions to be found in the appendix or peritoneum. When one has operated on fifty cases of appendicitis he thinks he knows something about it, when he has operated one hundred cases he doubts, but when he numbers them by several hundreds he knows that he knows little or nothing about the conditions which he will find when he operates. The point then, which we would make is that we can come to no other conclusion except the fact that, as soon as a patient presents symptoms of appendicitis, the safest course is that of immediate operation. We do not question for an instant, nor does any surgeon, that the large proportion of cases of appendicitis would recover from the attack without an operation, but it is those who do not recover that we are trying to save, and those who did not recover without operation if they had come to the surgeon and were operated early, ninety-five out of one hundred would recover.

Dr. James E. Moore, Minneapolis—I differ from my esteemed friends, Drs. Deaver, Murphy and Harris. I agree with Dr. Deaver that when the patients are under his care and in his hospital that they ought to be operated upon just as soon as the diagnosis is made; but I maintain, as a teacher of students and as a practitioner of surgery, who is to-day talking to many general practitioners, that the doctrine that every case with a diagnosis of appendicitis must be operated at once is pernicious and dangerous. If that doctrine is to be taught to our students, laid down as strongly as Dr. Deaver always does lay down everything, he will feel it his imperative duty when he has a patient out in the backwoods to advise operation when he has no skilled surgeon at hand to operate; the consequence will be that country graveyards will be filled with cases of appendicitis that might have recovered had they been let alone. We are all extremists in some things. Dr. Deaver claims to be one, and I understand he prides himself on being an extremist in this matter; but if you will stop to think, you will agree with me that we do not look for the best of anything from extremists. We must have these extremists. They are useful to point out to us that happy middle ground that is always the safest. We can not lay down hard and fast rules of anything in surgery where human life is involved. I maintain, therefore, that these men who assume this extreme position are teaching a dangerous doctrine. You will notice that they are men whose experiences are in the hospitals in the large cities. To those of us who are in cities like Minneapolis, where there are only two hundred thousand people, things are looked upon differently. In the country you are held responsible individually for these things, and you must recognize the right of your patrons to an opinion. You can not lay down hard and fast rules; you must give certain medicines or give the knife. And, while I admit with Dr. Harris and others that you can not tell what is inside of the abdomen, I maintain that if every case is operated on under all conditions and by every man who has a diploma, the percentage will run greatly above 17 per cent., which after all is not so very much lower than the "let-alone" treatment. With reference to the removal of the appendix in every case operated upon, I would draw that same line, making it depend upon the experience of the operator and the environment. I am in the habit of telling my students, "When you begin your work you will probably have to make an opening there big enough to get your hands and feet in to find anything you are after. If you see the appendix and feel it, take it out, but don't go pawing around for it." On the other hand, I am sure that most experienced surgeons will remove the appendix in the vast majority of cases. With reference to the blood count. I was very enthusiastic at first, and I had my internes working on it constantly, but I have got to the point where I only want it in certain few cases, but ordinarily it is a disturbing element. It does not give me positive information when I need it most, and many times it gives me information supposed to be positive that is misleading. In some cases with great pockets of pus we do not get sufficient leucocytosis to demand operation. Many times we get a marked leucocytosis with a simple catarrhal appendicitis.

Dr. Robert T. Morris, New York—It seems to me that we ought to adjudicate the term "extremist." It is a matter of the application of the word. When a visitor in my barn, looking over my Jersey stock, drops a match in the hayseed on the floor and the match is still burning, I am an extremist on the subject of putting out that match and I do not care who calls me one. It is a question of understanding the subject with which we have to deal. With appendicitis we are dealing with an infection; no one can tell the limits of it any more than you can tell the limits of the match in the hay on my barn floor. It may go out. I have seen them go out before I could get to them, and I have been saved the trouble of operating on that match. I agree with Dr. Moore's position on most of the points, but we must make our position more clear by saying that we are to teach our students principles, just as the law class is taught principles. Can we say to the law class: "You men, half of you, are not to be taught principles in law because you will go out and get your clients in trouble. Your clients are going to lose estates and this widow is going to lose all that belongs to her. You are going to get your clients into trouble if I teach you principles!" The law class is to-day taught principles and the medical class is to-day taught principles just as the law class, and we are to explain the reasons why cases of appendicitis are to be operated on as soon as a diagnosis is properly made. I would emphasize one point particularly. I assume the diagnosis is made by men who are qualified to make it and that it is properly made, and then, it seems to me, our line of action can safely be left to the judgment of men who are graduating from the kind of schools in medicine that we believe in to-day.

Another point—Dr. McKnight's leucocytes. This is a matter of much collateral interest—the blood count—but it is not one of determining interest. I will not go over the ground that Dr. Harris covered, except briefly to state that all of his points were those of a practical man, and I agree with all he made. Many of our most violent cases have not had time to develop a leucocytosis. When a concretion is about to perforate the wall of the appendix, we have a marked spasm of the muscularis of the entire bowel, a definite progressive appendicitis, and yet little to stimulate development of the leucocytes, a development of leucocytes which would determine the question as to whether we are to operate or not. We must determine that point from our other sources of knowledge and must look upon the blood count as a scientific, valuable addition to our knowledge of the phenomena occurring in the course of these cases. This keeps me still on the point of leucocytes, and Dr. Deaver's and Dr. LaPlace's papers both bear on this point. It seems to me to-day that our whole plan of action in the treatment of appendicitis consists in forming a strong alliance with the leucocytes. We are dependent upon leucocytes to-day for our help in trouble. Anything which shocks the patient interferes with his development of phagocytes. The thing for us to learn to do in the treatment of appendicitis, with peritonitis—grave septic complications—is to let the patient alone as much as possible when operating and allow him to develop his phagocytes. If we introduce continuous irrigation, I am afraid that we are taking some of that patient's strength. If we use gauze packing extensively, I am afraid we are taking some of the strength that is required for manufacturing the leucocytes. If we make multiple and extensive incisions, with wide flushing of the peritoneal cavity, we are using up the strength that the patient requires for manufacturing leucocytes. Leave him alone as much as possible; allow him to manufacture his phagocytes. That is the line of treatment today; that is the line of treatment that is to give us our best statistics. It certainly has in the hands of some men. It certainly is a matter to be determined, after all, by statistics. We do not care for this or that man's theory, so long as his statistics show his experiences are right. The matter of blood washing is more important than the matter of peritoneal washing. I believe, in short incisions, rapid washing out of the chief toxin-collection of fluid with hydrogen dioxid washing, without gauze packing, without extensive drainage, leaving some pus often, but giving exit to the chief toxin-bearing collection, and letting the leucocytes manage the rest. Clark's position was the opposite of Fowler's, yet Clark's statistics were the best we had up to the time of the presentation of Fowler's paper. Clark placed the patients with hips up and allowed them to drain through the diaphragm. Fowler drains the other way, but we know that both plans have their good points and have given remarkably good data. Back to the point of blood washing. These patients are loaded with toxins; their sympathetic ganglia are poisoned with toxins circulating in the blood. If we distend the blood-circulating channels with salt solution, fifteen hundred cubic centimeters at a time of physiologic salt solution, many of these patients who are going down, hour by hour, a little worse, worse to-night and worse to-morrow, and to die on the following day, will turn instantly for the better in fifteen minutes after you have distended their blood vessels with physiologic solution, because the toxins are being eliminated by the emunctories. The dull eye and the thirst change, not to-morrow, but in ten minutes after you have done this, and I do not know why it is forgotten by so many who know so well the points in washing out the blood, by the method of injecting salt solution into any available vein; it excites the emunctories to rapid work and causes the elimination of toxins circulating in the blood.

Dr. F. D. Smythe, Memphis—What should concern us most as surgeons should be the consideration of those principles that will save the greatest number of patients suffering from this disease—appendicitis. I do not think that we should be handicapped by the consideration of a procedure that would cause additional delay in according these patients the proper treatment, which treatment is surgical if seen at the outset by a surgeon. No one questions that the ideal treatment in all cases of appendicitis would be immediate operation after diagnosis, if made by a competent man. If this practice could be carried out we would see none of those conditions described, such as peritonitis, extensive suppuration with perforation of the intestines, resulting fistulæ, etc. It is an operation unattended with danger if performed by a man who knows what asepsis and careful technique are, and the resulting mortality could not and would not exist. We can not be held responsible for those cases which are brought to us suffering from septic peritonitis—operation here does no good; they will die with or without an operation when permitted to go this far. Fulminating cases are, as a rule, not benefited by late operation. Here operation must be performed at the very outset if we expect to accomplish anything by it. The successful treatment of appendicitis depends upon its early recognition and prompt surgical intervention. One point with reference to drainage. I am satisfied that a few cases of appendicitis have been saved, with suppuration involving a large area in the right lower quadrant, by making a counter opening in the loin. It is indicated in cases where the appendix points upward, in order to establish more perfect drainage a large rubber tube is drawn through, maintaining thorough drainage; this would not be attained if gauze packing or the mere insertion of the tube were depended upon. This procedure has served me well on all occasions where its employment was indicated.

Dr. John B. Deaver, Philadelphia, in closing—I am delighted with this discussion. It is the best on appendicitis that I have ever heard. I feel that if I should sit down and say nothing more, that this fifty-second session—and especially the surgical section—would go down in history. I feel that I have consumed too much time. Dr. Steele, Chicago, said he was not fortunate in making postmortem examinations. What is wrong in opening your wound and saying nothing to the members of the family? That is part of the operation. Dr. Murphy, Chicago, raises the question of peritonitis where we have an eroded peritoneum reddened and excoriated. It is beyond the aid of mortal man to be of any assistance. Therefore, always at the operating table I class these cases among the fatalities at the time of the operation. I believe much is accomplished in the way of relief from tension. Another question Dr. Murphy asked me was in regard to cases where the pus was creamy yellow—I would call these cases general infective peritonitis. These invariably get well. I have a number that my house doctor in the German Hospital operated on during that stage and all have gotten well. I have never lost one as yet when I have gotten them early. Dr. Murphy also remarks as to the type of infection. That is most important. It is not necessary for me to go into an examination of infection by the colon bacillus, staphylococcus, etc. With Dr. Murphy, too, I am sure no one can tell what is going on inside of the belly cavity and these fulminating cases of appendicitis mislead us if we delay the operation. The only sign, if I would call attention to it at all, that makes me fearful of the condition inside of the belly cavity, is pronounced general rigidity of the belly wall. When I see a patient with the belly walls like that table, on which I can not make any impression, in perfect health, has a normal temperature, but an increased pulse rate, with a history of sudden onset and abdominal pain, I am always apprehensive of that result. Anesthetize those patients, and, if under the effects of ether that muscular rigidity does not entirely disappear, that suffices oftentimes to bespeak the condition we will meet with inside of the belly cavity.

In reply to Dr. McKnight, who raises the question of blood count. There is much to be said on the blood count. I do not believe delay should be permitted on account of it. I believe that we should operate, then make the blood count, if time is of any question. I believe, too, in the presence of gangrene, that leucocytosis is dangerous as a guide, because it is unreliable. Irrigation in general peritonitis, if it is the type that Dr. Murphy referred to, does not mean anything, and, with Dr. Morris, I believe that the less you subject the patients to the resisting power of additional attacks, the better likelihood of the outcome.

The question of Fowler's position—I have used it ever since Dr. Fowler described it and with happy results.

To my friend, Dr. Moore, I will say that we have to be careful in the handling of students, but, at the same time, truth is mighty and must prevail. The teacher that stands before a body of young men, who are going out to meet the responsibilities of a doctor's life, and teaches them the doctrine that Dr. Moore brought forth here, will be the means of erecting many an appendiceal tombstone. Give us teachers who have the courage of their convictions. I feel very strongly upon this point, for I feel that it is absolutely wrong to appear in any but the proper guise. Therefore, I am firmly of the opinion that an early operation is the *sine qua non*.

Success of Sclavo's Anti-Anthrax Serum.—The *Gazetta degli Ospedali* states that eight persons were taken sick after eating meat from a steer that had died from anthrax. All promptly recovered after treatment by injections of Sclavo's anti-anthrax serum at the Siena University Clinic. Fourteen other persons in a similar epidemic at Santa Croce were cured by the same means, and others at Castel and Colle Val. Alberto describes in detail in the issue for September 1, another severe case cured by the serum six months after the date of manufacture. Sclavo offers his serum free of charge to physicians on request.

MODERN ASPECTS OF CONGENITAL OSSEOUS MALFORMATIONS.*

CARL BECK, M.D.

NEW YORK CITY.

The most frequent abnormality of the upper extremity is polydactylism. If there is but a rudimentary finger attached loosely by a pedicle which does not contain any phalanges at all, removal is simple.

In Case 1, illustrating a boy of four months, the supernumerary digit, as shown by the skiagraph, contained no bone-tissue. (Fig. 1.) Removal was naturally easy. In the same case there was a partial fusion of the third and fourth metacarpal bones, a condition which would not have been diagnosed without the Roentgen rays.

Case 2 represents the more complicated type of true supernumerary digits articulating with each other. There was also a supernumerary digit attached to the little toe. (Fig. 2.)

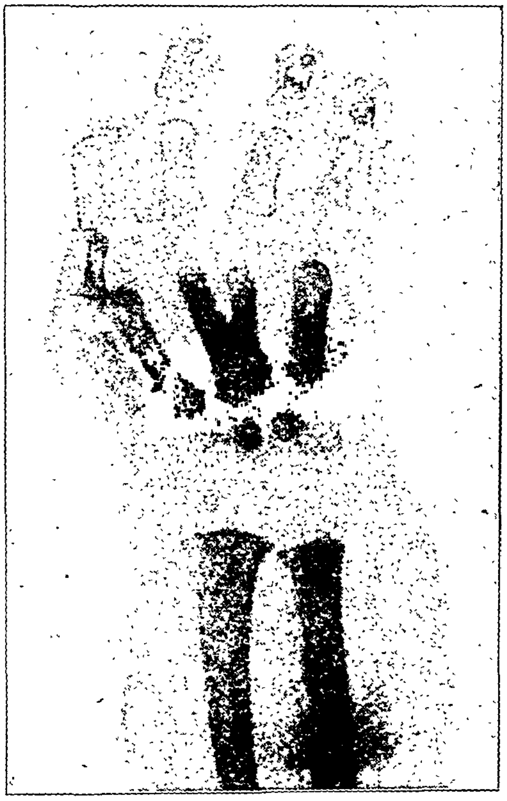

Fig. 1.—Non-osseous supernumerary digit and synostosis of third and fourth metacarpus.

Case 3 shows a true supernumerary phalanx attached to the thumb and articulating with the first metacarpal bone. It is nearly as large as the normal phalanx and possesses a well-developed nail. It is held in abduction.

Case 4 illustrates the complicated type of syndactylism in a boy of four months. The parents are in good health and emigrated from Hungary eight years ago. The second, third and fourth digits appear to be fused together, each one of them, however, possessing its own nail. The skiagraph shows fusion of the first and second phalanges of the third and fourth digits, while their third phalanges are free. The little finger is more developed than the slightly deformed thumb. The carpus is not ossified yet, and shows no shadow therefore. Under the guidance of the Roentgen rays it was easy to divide the phalanges. The middle finger was protected by a large longitudinal flap taken from the dorsum manus. The other two fingers were covered by their own integument, longitudinal flaps being formed from the palmar surface for the second finger, and another from the dorsal aspect of the fourth. The final result is good.

In syndactylism the Roentgen rays always prove whether its nature is cutaneous or fibrous or osseous.

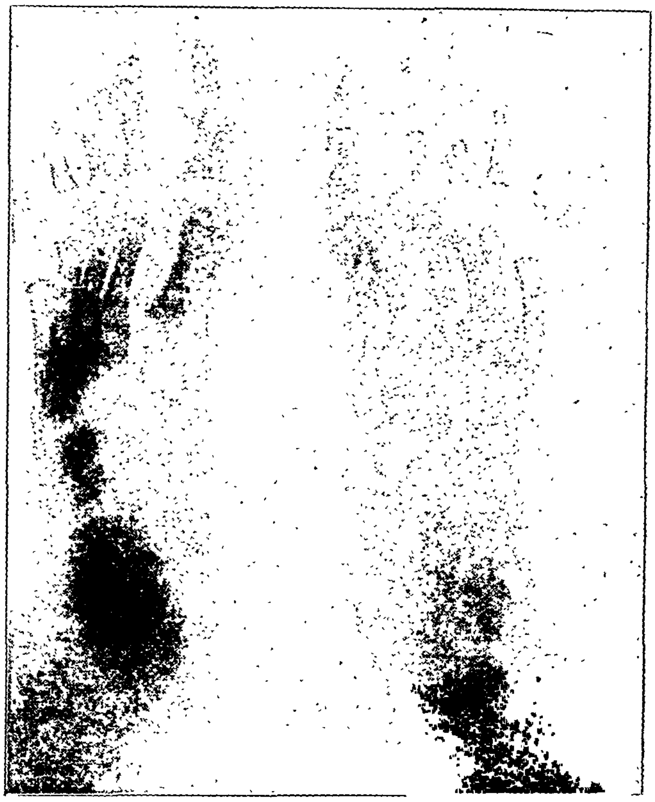

Fig. 2.—Supernumerary phalanx of the left little toe.

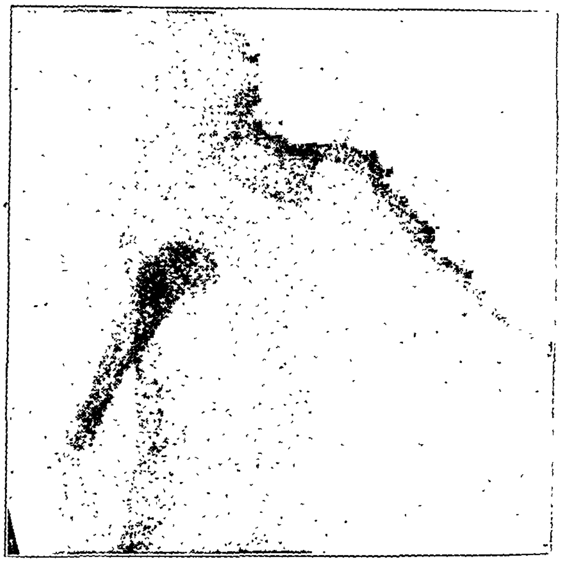

Fig. 3.—Congenital fracture of radius and ulna.

Case 5 shows congenital exostosis in the second phalanx of the index finger in a boy who was born in Germany nine years ago. The family history showed nothing abnormal. The Roentgen rays demonstrated the benign character of the osseous growth clearly. In view of the presence of functional disturbance removal with the chisel was undertaken.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee of the Section: Drs. H. E. Tuley, Edwin Rosenthal and Samuel W. Kelley.

Congenital deficiencies are naturally much less amenable to corrections. But that even in desperate cases of this kind surgery is not without resources is made evident by the transplantation of a toe to the hand, successfully undertaken by von Eiselsberg.

It seems to me that this special branch of surgery is too much regarded as a stepchild. Considering that in the lower animal, as long as in the embryonic stage, regeneration of large portions of the head and trunk are possible, it should be expected that the new-born child—in a smaller proportion, of course—also offers more changes for regeneration than the adult. If the germinal layer is only present, further development of tissue can be looked for. If a part of a phalanx is properly severed, its individualization is a matter of great probability, provided the bridge remaining has preserved sufficient vascularity for nutrition, that there is no overextension of the flap and thorough aseptic precautions are taken.

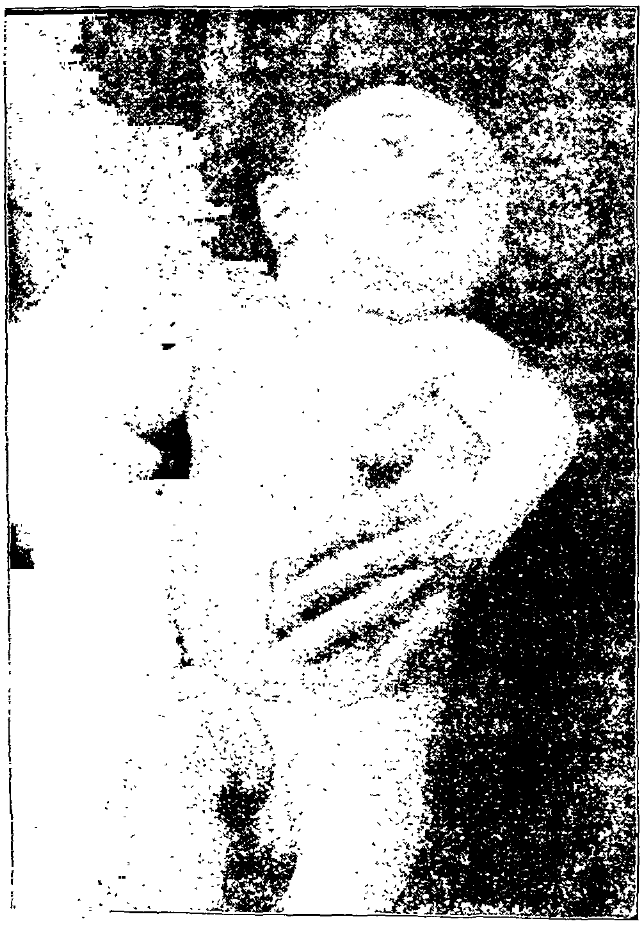

Fig. 4.—Congenital absence of the radius and ulna.

Fortunately, the Roentgen rays are predestined to give an impetus for a new operative strategy in this much neglected field. Thus, in a case of brachydactylism, combined with electrodactylism, the Roentgen rays proved to be of great value. In Case 6, that of a boy three months, there were five rudimentary fingers. The skiagraph showed the presence of one phalanx of the thumb and of two phalanges each of the other fingers. The child was the first born of German parents, who emigrated five years ago. The mother is healthy. The father was suffering from tubercular knee at the time of the birth of the child, and died from general tuberculosis a year afterward.

Under the guidance of the Roentgen rays I performed a flap operation on the principles set forth in Case 4, between the first and second finger-rudiment. Thus a fairly good thumb was created. The case, however, offers two more points of interest. In the first place there was congenital fracture of the ulna and radius at their lower third. (Fig. 3.) The forearm could be bent easily at the seat of the fractures. After wiring the fragments union became perfect. There was, furthermore, congenital constriction at the region of the surgical neck of the humerus, where a deep furrow encircled the whole circumference of the arm. Palpation was unable to detect any soft tissues between the integument and bone. An exploratory incision revealed the presence of the fragments of the

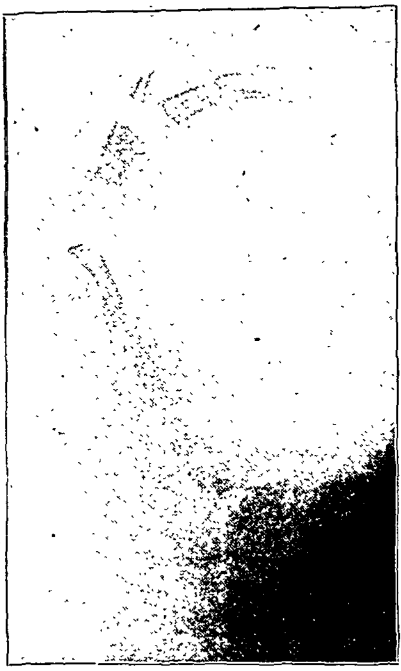

Fig. 5.—Skiagraph of Fig. 4.

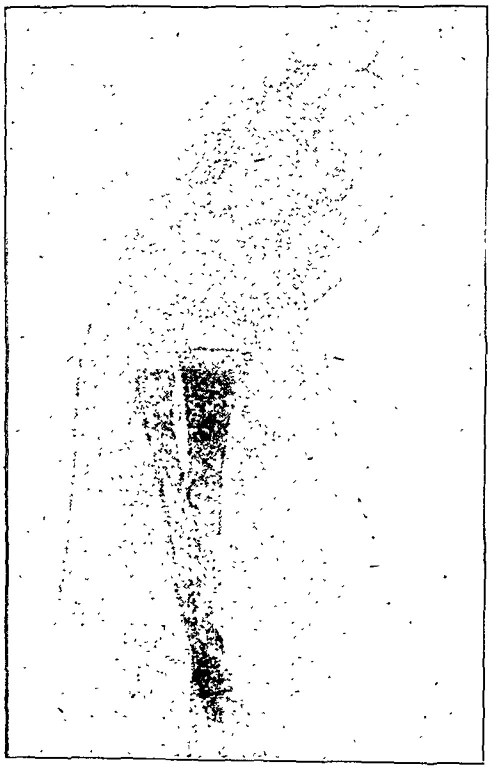

Fig. 6.—Congenital absence of metacarpi and phalanges of the second, third and fourth fingers.

biceps, triceps and deltoid muscles. Their edges were refreshed and united with catgut. For relaxation, two deep wire sutures were introduced from without. The result is fair according to the last report, fourteen months after the operation.

It may be added that the otherwise well-developed right hand shows a moderately deep constricting furrow near the metacarpophalangeal junction of the middle finger, which did not seem to demand surgical interference.

Case 7 shows congenital club hand associated with absence of the radius and ulna. That there are only three fingers is shown by the photograph (Fig. 4) and that but three metacarpal bones are present becomes evident by the skiagraph. (Fig. 5.) The patient is a boy of six weeks, born in New York. The family history is good. The parents emigrated from Italy two years ago. The father is 66 and the mother 41 years old. Both are in good health. There are three previous children, all of whom are well. The left arm of the boy is normal, with the exception of the thumb, which is partially ectrodactylic, like the thumb reproduced in Fig. 3. The muscles do not show any atrophy. Extension and flexion of the wrist was possible to a moderate extent.

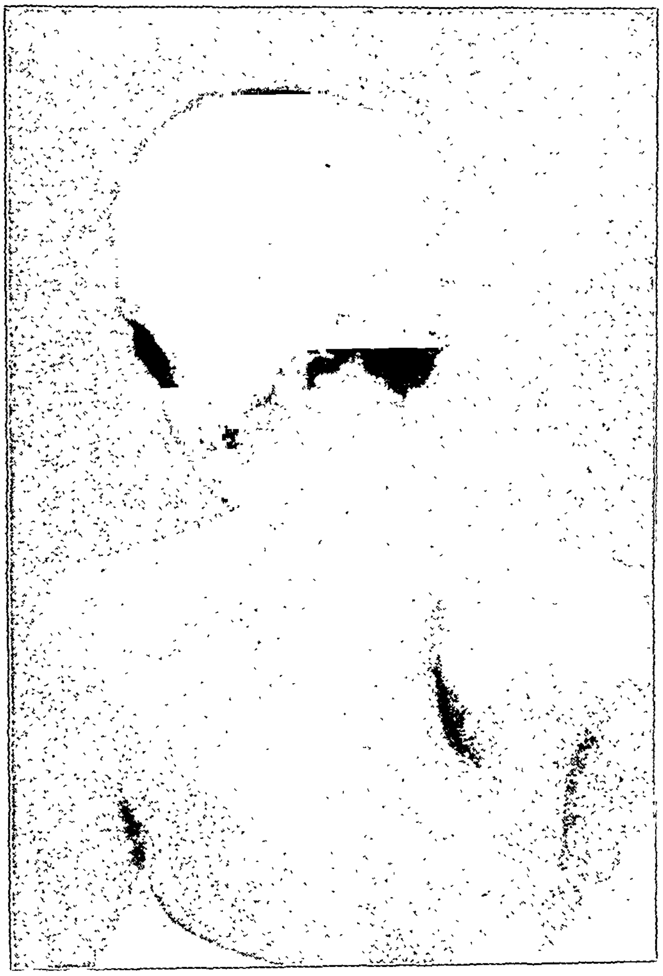

Fig. 7.—Congenital scapular asymmetry.

I attempted to improve this deplorable condition by creating a thumb after the principles carried out in Case 6. For this purpose a dorsal incision was made down to the first metacarpal bone, which I divided longitudinally, thus making a kind of bifurcation. The phalangeal end was severed entirely, but the carpal end, after being longitudinally fractured, was left in slight connection with the metacarpal bone. Thus a new bone was obtained, which was surrounded by dorsal as well as palmar flaps. How far this new fourth finger can be utilized can not yet be known, the child still being under treatment. The skiagraph shows its position. The treatment of the club hand by osteotomy and reversion of the abundant skin to the opposite side will be attempted later on.

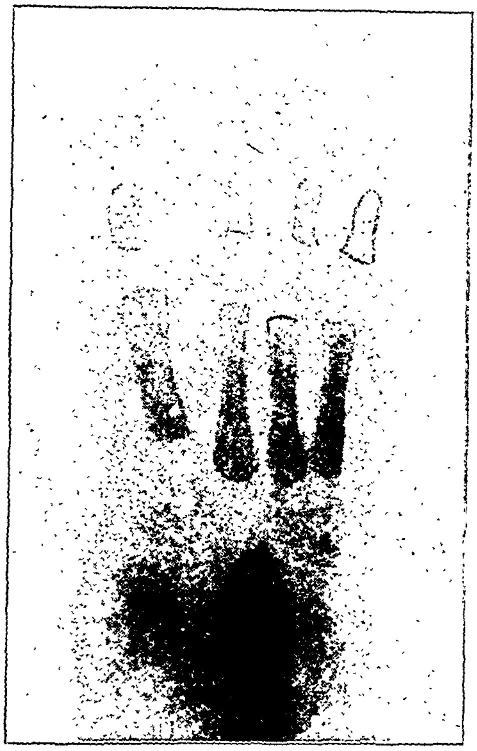

Fig. 8.—Congenital absence of one metatarsus and corresponding phalanges.

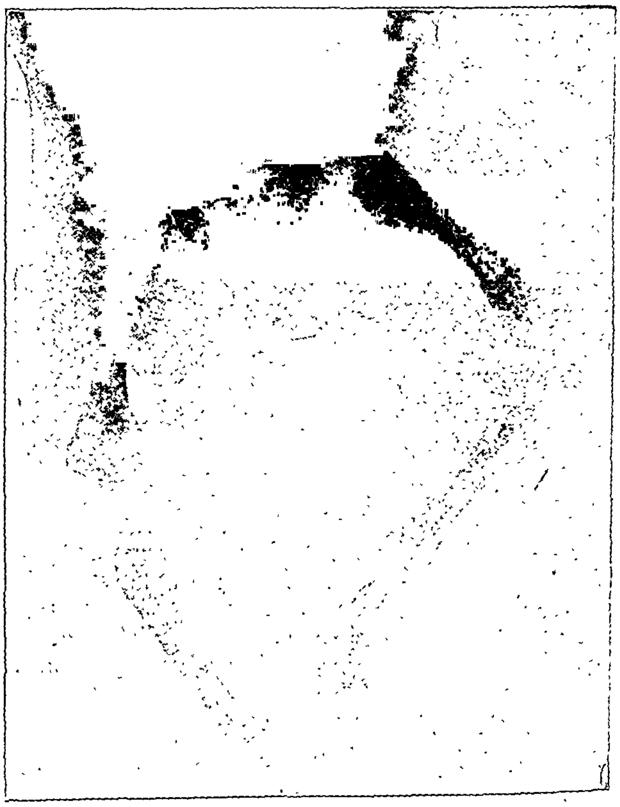

Fig. 9.—Congenital shortening of the right femur.

Case 8 represents a boy of three weeks, born from healthy German parents, who shows neither carpal nor metacarpal bones. There are three phalanges at the ulnar and two at the radial side, the latter undoubtedly representing the thumb. (Fig. 6.)

Case 9, which was observed before the discovery of the Roentgen rays, may be added in view of its rarity. It represents congenital absence of the arms and forearms. The clavicle as well as the scapulæ were normally built, but of smaller size. Neither the glenoid cavities nor the coracoid processes could be made out well. Instead of the round shape of the shoulder an angular prominence is noted. Adjoining the ribs a small bone could be felt below them, which might have indicated the rudimentary representations of humerus and antibrachial bones, but their nature could not be clearly defined. To this the rudimentary hand was attached, which contained five fairly developed fingers, provided with nails. The metacarpal bones could not be made out distinctly.

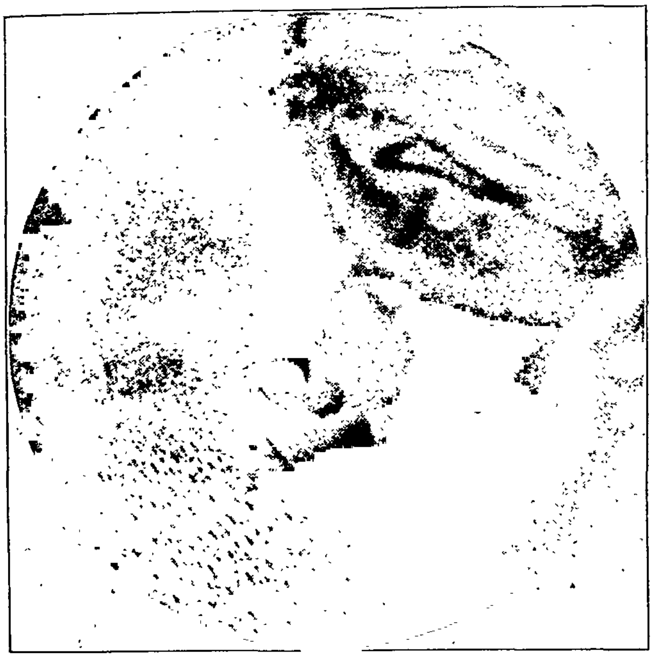

Fig. 10.—Congenital hypertrophy of toes.

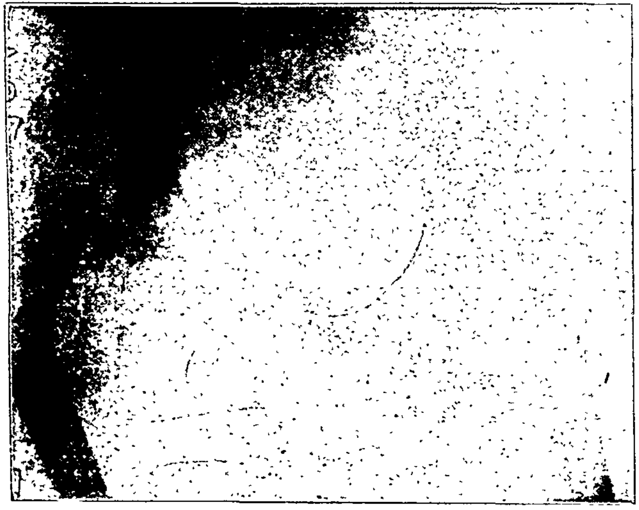

Fig. 11.—Congenital dislocation of both hips.

The patient, a boy, born in New York, was ten months old when the photograph was taken. The parents emigrated from Germany fifteen years before the birth of the child. Both are fairly well, but poorly nourished. One sister died from meningeal tuberculosis. Two brothers and one sister are alive and healthy. The patient died from dysentery when a year old.

Case 10 shows congenital scapular asymmetry in a girl of 11 years. (Fig. 7.)

Case 11 (Fig. 8) shows the presence of four metatarsi and their corresponding phalanges only, in a girl of seven weeks. The family history revealed nothing abnormal. There is no functional disturbance.

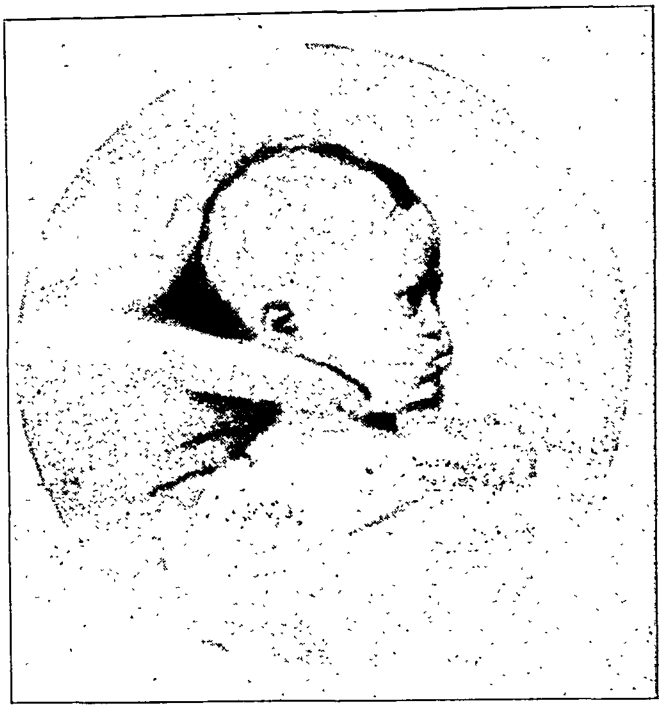

Fig. 12.—Congenital absence of nasal bones and insufficient development of nasal processes of supra-maxilla.

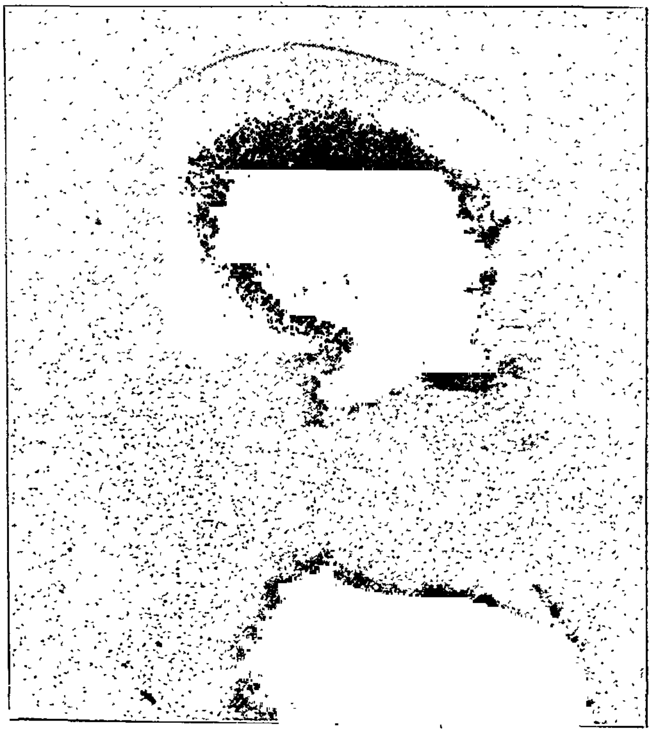

Fig. 13.—Skiagraph of Fig. 12.

Case 12 (Fig. 9) represents the lower extremities of a boy of three weeks. The left extremity is normal, while the right one shows shortening of the femur to the extent of an inch. There is no muscular atrophy. Whether intrauterine fracture of the femur was the cause of the shortening could not be elicited. From the study of the skiagraph it seems to me to be improbable. Shortening of the healthy femur for the purpose of equalization was considered. The degree of functional disturbance can, of course, not be estimated yet.

Case 13 shows congenital hypertrophy of all toes, especially of the second, in a boy of four months. They appear very thick and puffy like in elephantiasis, but the skiagraphs show normal structures. (Fig. 10.)

Case 14 shows congenital dislocation of both hips in a girl of 9 years. The cartilaginous epiphyses of the femurs are dislocated and the right femoral neck shows extraordinary bending. (Fig. 11.)

Case 15 represents congenital absence of nasal bones and insufficient development of nasal processes of the superior maxilla in a boy of two months. The infant is poorly nourished. The parents came from Russia five years ago and are well. There are four healthy children besides. (Figs. 12 and 13.)

It may be noticed that none of these deformed children were born of American parents and that heredity could not be made responsible in any of them as an etiological factor.

SOME SUGGESTIONS REGARDING A DEPARTMENT OF SCHOOL HYGIENE.*

LEIGH K. BAKER, A.M., M.D.
Supervisor of School Hygiene of the Public Schools of Cleveland, Ohio; Assistant in Ophthalmology, Lake Side Hospital, Western Reserve University.
CLEVELAND, OHIO.

Definition.—From Dr. William H. Burnham, professor of school hygiene at Clark University School for Teachers, I have received this very good general definition of school hygiene. "School hygiene has to do with the conditions which favor the normal healthy development of children, so far as determined by school environment—school sanitation—and school programs, sequence of studies, text-books, and methods of study and instruction—hygiene of instruction."

Rationale.—Quoting from a former paper, I will again cite the fact that those nations which have exercised a powerful and elevating influence have been and are those which have exercised a care for the health of their citizens. Within fifty years indisputable evidence has induced nation after nation to recognize the value of sanitary science as the preserver of national health and wealth, as well as elemental to military success.

In a democracy self-preservation demands an educated citizenship. This underlying principle allows the state to say to the prospective citizen: "You shall, for an adequate length of time, be placed under such instruction as will make of you an honest, intelligent and useful citizen." Anything short of this will not insure the stability of the state. An elemental condition of useful citizenship, however, is a fair degree of physical health.

Moreover, there are certain unsurrendered rights of the citizen. Among these is the right to as fair a degree of health as his ancestors, and his right and moral duty to transmit to his offspring as good or better health than he himself enjoyed.

Hence, it is both the interest and the duty of the state to insist, when it places the individual under formative educational processes, that the physical basis in the educational structure be adequately and properly laid. For the most part the state has not assumed to dictate methods to the educator, simply holding him responsible for results. Both opinion and fact testify that the desired improvement in health from grade to grade has not been attained. In America this is the more strikingly true of the children of the cities. These rapidly built wildernesses of incongruous construction express little evidence of any desire to protect and foster child life. Their dark, noisome alleys and tenements contain millions of the miserable offspring of ignorant foreigners—poorly born, poorly housed, fed and clothed, with crooked spines, misshapen skulls and pathological eyes or ears, with little in their environment to produce self-respecting, self-supporting citizens, but with many conditions which tend to convert them into a dependent class.

To thousands of acres of such slumdom, public education alone, in any large sense, stretches out the reclaiming hand. Upon it is thrown the responsibility of converting these children into people who are physically able to compete with the children of protected labor and capital. Either this must be done or we must prepare for a steady increase in the dependent classes. The proposition is a simple one. Shall we put sufficient money into the schools to enable them to produce self-supporting citizens, and then hold them strictly accountable for results, or shall we half support them, paying little attention to the health of the children, and later on spend much larger sums of money for the construction and maintenance of hospitals, dispensaries, police stations, saloons, reform schools, workhouses, etc.?

Fortunately, public sentiment has become so favorable to better school sanitation that even now this can be made an issue in a school election. Not only is this so, but the school official who disregards his pledges in this matter can easily be defeated in a subsequent election. Physicians should combine with good organizations to secure the defeat of all such officials. It is especially appropriate that the city physicians use their combined influence with all civic organizations in this matter, for they, more than any other class of men, are forced to carry the steadily increasing burden of indigency. At the same time they understand better than does any other class of men its causes and appreciate more fully its large extent. Of all men, they realize most keenly how impossible it is for the homes of thousands of these children to evolve an effective type of citizenship.

Content.—Leading authorities place the following within the province of school hygiene:

School Diseases: Those of the respiratory tract, of the spine, of the nervous system, and of the special senses; general infectious diseases; the eruptive fevers.

Hygiene of Instruction: General; school age; amount of study; home study; arrangement of work; number of sessions per day; discipline; punishments; public examinations; number of pupils to a teacher; regularity of attendance; courses of study; individual branches—their comparative effect on health.

Personal Hygiene of Pupils: Food; clothing; sleep; exercise; bathing.

Physical Education: General; history; literature; as a department of science; as a department of hygiene; as a pedagogic discipline; as a practical art.

School Grounds: Soil; area; dimensions; surfaces; planting; school gardens; play grounds.

Buildings: Placing in grounds; foundations; basements; materials; general dimensions, as affecting school-room construction; heating and ventilating; lighting.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee of the Section: Drs. H. E. Tuley, Edwin Rosenthal and Samuel W. Kelley.

School Rooms: Dimensions; shape; furniture and its placing; floors; blackboards; colors; lighting; heating and ventilating; cloak rooms; supervision of conditions.

Furniture: Adaptability; cardinal points in construction; supervision.

Ventilation: Introduction of good systems; strict supervision of the same.

Heating: Different methods; temperature records; atmospheres; supervision.

Cleaning: School dust; methods and frequency of cleaning; supervision.

Sewerage: Systems; ventilation; supervision of closets, urinals, etc.

Since many of these phases of the subject will be discussed in the papers to be read, this paper will content itself with the mere mention of these important phases of school hygiene.

Introduction.—This may be effected in several different ways.

1. Upon the recommendation of the superintendent of instruction the board of education may consider the matter and arrange for a department. This presupposes a progressive superintendent, backed by an unusually intelligent and progressive board of education. This combination is rather unusual. Where it exists, however, the superintendent and board should feel that they have the moral and political support of the profession, as well as its assistance and counsel. A strong committee from the leading medical society can render services of great value in this connection. The factors most affecting the success or failure of this plan are the school board, the superintendent of instruction and the teaching force. Hence a few comments concerning these will be in place.

During the past six years we have attempted to introduce a department of hygiene into the Cleveland schools, following this plan, and the result is still doubtful. Here the federal-plan law is supposed to dissociate the department of instruction from the distinctively business department and to take the former out of local politics. Perhaps it accomplishes this, year for year, in a larger degree than is the case under the usual forms of school board organization. Notwithstanding, however, the earnest efforts and yearly recommendation of our superintendent, Mr. L. H. Jones, it has been impossible to secure the adequate co-operation of the school council in the establishment of a department of school hygiene. The work has grown with the teaching force and with the public to the proportions of a full-fledged department and is so recognized on all hands, except by this singular body. On the other hand, during the past year there was introduced and favored by certain members of the board, a measure which was calculated to divide the work in school hygiene, placing several medical inspectors directly under political control and so dividing the whole matter as to prevent the possibility of an effective department. It is probable that this measure would have passed but for the vigorous protest of many of the leading physicians of the city. This, together with other acts of a similar nature, leads me to conclude that city school boards, as at present composed, are not competent to introduce and foster adequate measures for the conservation of the health of the school children. Neither are they willing to employ and follow the suggestions of those who make such matters a life study. Hence it is necessary, if this plan is to be successfully carried out, that certain limits of eligibility should be placed upon membership in these bodies, in order that they may contain men who are vitally interested in the health of the children, as well as men of sufficient executive ability to secure sanitary school conditions.

Among other qualifications, they should be men of mature judgment, but an age limit, say 55, should exist. They should have a vital connection with the schools through having children therein. They should be men of assured executive ability through having succeeded in business. They should not be known as local politicians. These matters are emphasized because the school board is the snag on which such reforms usually stick, and because physicians, through combination with other organizations of good citizens, can materially assist in the election of an effective school board.

The average superintendent, supervisor and principal will assert that he is interested in the health of the children. In a general way this is true. But it usually requires a fierce flame of public opinion to secure adequate action on his part. Frequently he is content to foster the traditional subjects, grammar, arithmetic, etc., and let other people look after the health of the children. He has not yet realized that the problems of education in the wretchedly built and governed American city of to-day are quite different from those of the towns and villages either of to-day or of a generation ago. It takes an occasional revolution in school management to awaken him to this fact. Such a revolution the medical fraternity can, if necessary, inaugurate. On the other hand, if the superintendent is a leader in educational matters, he will need the hearty and continuous support of all medical men, in order that he may carry out his plans in conserving the health of teachers and children, in spite of the constant interference of scheming politicians, which he is sure to encounter at every turn.

So evident has been the growth of interest and accomplishment among the rank and file of the teachers, that I am pursuaded that the teaching force does not stand in the way of the introduction of school hygiene into city schools. In Cleveland the great majority of the teachers have given the work suggested fully as much attention as justice to other branches will allow. The instances are very numerous in which teachers, at their own expenditure of time or money, and often both, have taken care of pupils whose parents were unable to do so. Many of the teachers are far more enthusiastic about all such matters than are any other class of people. They deserve the highest praise for their efforts along these lines.

2. Where the superintendent or the board, or both, are inoperative the problem can be solved, if an able man is available, by his election to the executive position—that of director of schools, for instance. To do this the medical fraternity must secure the co-operation of all civic organizations which stand for the public welfare and through their efforts elect an executive, who is at the same time a sanitarian. The difficulty in carrying out this plan arises from the fact that the necessary business qualifications for this office are not easily secured, even without the special qualifications of a sanitarian.

3. This plan is the one which in my estimation covers the larger number of cases and is the more hopeful of immediate success. The committee on state medicine of the leading medical society, or the local pediatric

society, may call to its support in each school district the services of two or three physicians who are well and favorably known. They should be men who are established in practice. As special examiners, these men should give half a day or more to the work of subcommittees. The general committee should place in their hands lists of questions covering the more important phases of school hygiene. To secure such lists, reference may be made to the outline of school hygiene given in this paper. A list recently used in Cleveland is herewith given.

REPORT ON SCHOOL HYGIENE.

.... School.

1. *Provided* all should use them do you find the play grounds ample for the number of children in the building?
....

2. Are the play grounds in good condition for play? .....

3. Do you find any rooms from which the light is cut off by annex or other buildings? ....

4. Are the buildings so located and is the school yard of sufficient size to prevent the darkening of any of the rooms by the future erection of adjacent buildings of four or five stories? ....

5. Do you find any rooms in which the ratio of window to floor space is less than one square foot of glass to five square feet of floor? ....

6. Do you find that street noises interfere with the instruction in any of the rooms? ....

7. Do you notice a bad odor in any of the rooms?

8. Do you notice a bad odor in connection with the water closets and urinals? ....

9. Upon inquiry and inspection does the heating and ventilating system seem to you to be satisfactory? ....

10. Does the form and arrangement of the school furniture, as you see it in use, appear conducive to eye strain or spinal curvature? ....

11. Do you find the surfaces of the rooms, furniture and halls clean and in good condition? ....

12. How many basement, attic or recitation rooms, relief building rooms and storerooms do you find in use as school rooms? ....

Please add comments. What do you consider of *primary*—of *secondary* importance to the sanitation of this building?

Sub-Committee at School.

This refers more especially to matters in connection with school property. Questions are asked about conditions which a casual observer might see almost any time upon visiting a building. Here the work of many of the subcommittees has been quite complete and their reports will throw considerable light upon the situation. When they are all collected and tabulated the general committee, appointed by the Cleveland Medical Society a year ago, will have much of the necessary data with which to go before the board of education and, if need be, before the legislature. When it does this, a complete scheme for a department of school hygiene should be placed before one or the other of these bodies, with a strong recommendation for its adoption. In addition, the committee will need to follow up the matter and see to it that its recommendations are really followed. For there are usually enough scheming politicians on a city school board to evade or pervert such measures for their own personal benefit. These should be turned over to a committee of citizens, which, in co-operation with the local papers, will at once inform the public of any deviations from the right path. It will not require many reports, under these circumstances, to secure for the committee a more efficient school board.

Organization.—First of all, a department of school hygiene must have for its head a medical man who is at the same time a school sanitarian. For it is evident that the territory between the practitioner, whose observations are largely of pathologic conditions, and the educationist, whose observation is limited in large measure to mental phenomena, is a broad realm; the realm in which, for the most part, preventive medicine must operate. While it will be noted that it contains much which lies within the fields of actual practice and practical education, it is at the same time evident that there is a vast amount of opinion and a large collection of facts, which, for their advantageous assimilation by a city school system, requires the constant study of men especially trained for this phase of school supervision. On the other hand, that there may be actual accomplishment, rather than mere study of problems, the director of a department of school hygiene should possess the training and the sympathy of his fellow physicians, the skill of the teacher and the organizing ability of the educator. Hence, while he should be familiar with the experiences of the general practitioner, just as should any other specialist, yet his field of operation presents so many problems which neither the general practitioner nor the teacher are called upon to solve that he must be a specialist in this field of preventive medicine if he is to succeed in any large measure. His whole time must be devoted to the subject. Not only this, but he must be both level-headed and at the same time enthusiastic, an organizer, a leader and a worker. This field offers unlimited opportunities to an ambitious, well-educated young physician with plenty of money.

In addition to an efficient head, the department must have assistants. A large amount of office work will accumulate, which can be done by assistants at $50 per month, and which should not be done by a man whose time is worth several thousand dollars a year. To these should be added all special teachers of physical education, physiology and hygiene, etc. In addition, he should have at least one medical assistant to look after special cases and supervise in a general way the work of medical inspectors in the different districts.

Taken altogether, there ought to be sufficient help to enable him at any time to prepare quickly for the superintendent, or for the board of education, an exact statement concerning any condition within the schools which affects the health of teachers or children. Since the larger part of the work in his department lies in supervising the work of teachers, he should have plenty of special teachers, whom he has trained to supervise in an efficient manner the work of the regular teachers. Too much emphasis can not be placed upon this. The regular teacher in the grades needs constant assistance and encouragement. In Cleveland, at least, she receives entirely too little. She has many subjects to teach. Her program is crowded. Wise and constant supervision is required if each hour of the day is to be beneficial.

Medical Inspection.—Without medical inspection of special cases, a department of school hygiene is incomplete. Hence a fund should be available so that the director can call to his assistance physicians in the different school districts to act as his special medical examiners. The fund should be ample to secure the services of a sufficient number of experienced men. At stated intervals they should visit buildings and examine such cases as the principals may send to them. This inspection is of great value. It should not for a moment be thought that it will take the place of a department of hygiene. For many teachers and principals will not send all the cases needing attention to medical examiners unless they know that their rooms are closely watched by special teachers of the department of hygiene and that they are liable to be summarily called to account for negligence in the matter. I have satisfied myself on this point from investigations in city schools where medical inspection is supposed to cover the ground quite thoroughly.

Status.—The advice and the activities of this department should be entirely unbiased. This means that it should have no connection with school politics and should be entirely free from school traditions. It must be, therefore, under civil service regulations. I have held the position that its head should be an appointee of the superintendent of instruction. This certainly is much better than that any professional man should be hampered in his work through an appointment made by designing politicians. My own experience, however. is inclining me to the view that some position, equal with or above that of any present school official, must be created by the state before the health of school children receives the proper consideration at the hands of the educationist and the politician. These people fight each other, while the teachers go without adequate facilities, the children suffer and the people become distrustful of the efficacy of public education.

DIAGNOSIS OF THE BACKWARD CHILD.*

A. W. WILMARTH, M.D.

CHIPPEWA FALLS, WIS.

To formulate a definition which will describe the term "backwardness" in children is a task of considerable difficulty. It is made still more difficult by the extreme vagueness of the term as used by more recent writers, who use the terms "backward" and "feeble-minded" almost interchangeably. The truth of the matter is simply this, that there is no sharp line of distinction between the normal and the so-called backward child, or between the markedly backward or feebly-endowed child and the high-grade imbecile. No standard of mental activity has ever been fixed by which we can accurately determine these questions. Psychological studies, which are now being actively pushed. both in institutions for normal and abnormal children, promise in the near future to give us some more definite standard on which to base our diagnosis.

The variety of opinion on this subject is well illustrated by comparing the report furnished by Prof. Will S. Monroe, who gathered statistics of 10,000 school children in California by means of circular letters sent to the different teachers of the state, with those of others who have investigated the same subject. The report of this gentleman, compiled from the answers to his letter, shows the teachers considered nearly 10 per cent. of their charges as backward. Dr. Francis Warner, member of the Royal Commission to examine the blind, deaf and other classes requiring exceptional methods of education, out of 100,000 school children reported 7 per cent. dull and backward, while 1.6 per cent. required especial care and training. A report formulated from the examination of 42,000 children in Great Britain of the elementary school class between the ages of 7 and 13, gives 1 per cent. of defective children as the result. Mrs. Esten, supervisor of special schools in Providence, R. I., a city of over 150,000 inhabitants, states, in a recent article, that 50 pupils were then receiving instruction in their special schools, and that a recent canvass had revealed the fact that there were yet about 100 children who ought to be provided for. This is in decided contrast with the first statistics quoted, and shows how badly some standard for comparison is needed. Dr. Shuttleworth, in an article on the treatment of children mentally deficient, laughingly calls attention to the high standard Americans set for their children, and states that he was jocosely warned by an American friend, when he was about to make a tour of the institutions for the feeble-minded in the United States, that "He guessed I would find their feeble-minded children about equal to the average British schoolboy." It is plainly to be seen that in the teachers' returns compiled by Professor Monroe, each teacher must have filled her return according to her own individual judgment as to what should constitute a normal average.

I seriously doubt if it is true that a boy is necessarily dull or backward because he can not follow the curriculum formulated in the schools. However excellent this may be for the average child, there are many boys classified among the dull ones in their classes who turn out to be successful men after their school days are past. What they may lack in the faculty of merely memorizing, they more than make up in their power of reasoning and acuteness of judgment. Certain special faculties may be entirely absent, and while this lack may interfere with a boy's school progress, and may deprive him of much enjoyment, it may not in any degree interfere with his usefulness or affect the public estimate of his mental strength. These include such faculties, for instance, as the musical faculty, the mathematical faculty, discrimination of colors, etc. Our estimate of mental strength must rather be formed from his power of attention, his strength of memory, his efficiency in that method of reasoning which comes to us all instinctively in our early days, and which has been quite extensively treated by Carpenter, under the every-day designation of "common sense." On the other hand, abnormally slow perception, lack of power to fix the attention, distorted judgment, feeble memory, or a decided lack of moral sense are mental symptoms which would tend to place the subject among the backward class, and if different methods are faithfully tried to remedy these defects without marked result in a reasonable time, we may safely conclude that they indicate not only a backward but a feeble mind. Among the physical symptoms which are strongly indicative of lack of normal mental growth, the failure of articulate speech, where defect of the auditory apparatus, or that concerned in articulation does not exist, is the most conspicuous. In the absence of these physical defects, if the appearance of speech is delayed beyond the age of 6 years, it may be safely inferred that cerebral deficiency or lesion exists, and that some mental weakness surely accompanies the child's silence. Gait and posture are of some value, taken in connection with other symptoms. The former is apt to be slow and awkward, the latter stooping. The lately published observations of Wiley would tend to show that the sense of touch is generally less sensitive than in the average child. Sensibility to pain, especially in cases of marked dulness, is very frequently found and would tend to indicate a lack of tone in the whole nervous system. Family history will render valuable aid. As all mental action has a physical basis, and as the physical formation of each individual is but the sum total of ancestral traits, we may expect parental weakness to exist, either active or latent, in the offspring. Again, while a fair memory by itself is no indication that mental weakness or delayed mental growth is not present, a failing memory, or one that fails to respond to training by any marked improvement, may be looked on as abnormal.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee of the Section: Drs H. E. Tuley, Edwin Rosenthal and Samuel W. Kelley.

Much argument has been held whether moral sense should be regarded as a purely mental trait, and whether such a thing as moral imbecility exists. On the minds of those who have daily intercourse with large numbers of defective children, the actual existence of moral imbecility has been impressed as a disagreeable fact. So radical is this defect in many cases and so persistently will a child do evil and not good in spite of all efforts to lead him into right methods of thought and action, that one is forced to regard it as a perversion of normal mental development. Histories of cases have multiplied, following individuals with this affliction through life, and it has been demonstrated that in certain instances favorable environment would invariably bring into action the old evil practices. I have seen cases of this kind where the remaining mental faculties were nearly normal, in which the individuals insisted that when the impulse to do wrong came upon them it was stronger than their will power and beyond their control.

Let us glance for a moment at the normal growth of a child's mind, in order to understand better where failure may occur. After the instinctive acts of early infancy, the first thing that attracts us is the awakening of the power of attention in the child, such as the movement of its eyes as they follow a bright object. This faculty rapidly gains in acuteness and is the basis of mental growth. The failure of the proper development of attention, or we might say, the power of fixing the attention, is fatal to all attempts at education. From this time, as the various sense organs assume functional activity and convey sensory impressions inward to be stored in the proper groups of brain cells, we see the beginning of memory and the child becomes an animated interrogation point, worrying its elders by constant questions in its hunger for information. By this time we will be able to gauge somewhat the child's probable capacity for acquiring information, for on memory depends largely the child's mental capacity. Still a little later and the will power exhibits itself in control of these memories, formulating them into thought. A child learns to connect ideas or impressions which come to it through the sense organs and have been stored as memories, and to draw from them fresh ideas. In other words, the reasoning power develops and the child begins to reason from the known to the unknown. Furthermore, he begins to realize the value of each thought, or idea, and judgment has its birth. This is the most valuable of all mental acquirements. An individual with a rather weak memory may make a poor showing in school, and yet with acute reasoning powers may be able to make most valuable use of what he does remember. Such children ought by no means to be classed among the dull and backward. With the development of reason and judgment is aroused a respect for the rights of others, which forms the basis of moral sense. These faculties comprise, I believe, all the important elements of a normal mind. Their practical value in the mental framework varies much, but the failure of any one of them to appear at the usual age constitutes a backward child. Whether the child be temporarily backward or inherently backward or feeble-minded, is a question that we can decide only by examination and training. From what I have so far presented we may advance the following conclusions:

Delay in mental development may be temporary or permanent. In the former case we should speak of the child as merely backward, in the latter, as feeble-minded.

When this condition is due to a lack of proper training, or to temporary ill health, it may often be entirely overcome by proper treatment.

There has been no definite standard established upon which to decide whether a child is backward or not and we have no other guidance than by comparison with supposed normal children of the same age.

The qualities on whose absence or faulty development we form our judgment are acuteness of perception, power of attention, strength of memory, accuracy in reasoning and judgment and growth of moral sense.

Certain physical conditions are of aid in diagnosis of a backward condition, especially when considered in connection with delayed mental growth. Prominent among these are deformities; defects in or absence of articulate speech, not due to mechanical faults or deafness; defects in co-ordination and an awkward gait; defective physical growth and lack of acuteness in different sense organs. There are none of these absolutely pathognomonic, with the possible exception of lack of speech due to cerebral defect.

I can not close this paper without calling attention to one fact, which is, perhaps, not in direct accordance with its title, but yet is of vast importance from a sociological point of view. The comparatively large number of backward and high-grade imbecile children has led to the opening of schools for the special teaching of this class. It is probable that a large proportion of the children will be high-grade imbeciles, or those in which the mental defect is permanent. This may be largely masked by education and the children be graduated to marry and take a place in our great social life. These schools should be constructed so as to constitute clearing-houses to separate the inherently feeble in mind from those whose mental growth is retarded by circumstances temporary in character. So conducted they may be most useful. Education will not remove in a few years weaknesses which may have been generations in developing, and children thus matured will probably select one of their own mental grade in marriage, possibly a graduate from the same school. Hon. J. D. Alexander, before the National Conference of Charities and Corrections, in Topeka, cites a case where a woman was allowed to leave the Ohio institution and they now have eleven imbeciles, her offspring, to vouch for the success of such practice. Such instances are so common, though perhaps in less degree, as to form a valuable object lesson. If our high-grade imbecile girls and boys follow this course, we shall need many more such special schools than have been now established, and we may feel reasonably sure of pupils enough to fill them.

SPEECH AS A FACTOR IN THE DIAGNOSIS AND PROGNOSIS OF BACKWARDNESS IN CHILDREN.*

G. HUDSON MAKUEN, M.D.
PHILADELPHIA.

The subject under discussion is one of more than usual importance. It is said that there are, in Philadelphia alone, more than twelve hundred school-children who are unable to keep up with their classes and for whom no adequate provision has been made. This large number does not include the high-grade imbeciles and idiots who never get into the schools, but only those who are said to be "backward in their studies."

Scientific discussions often fail to be of value because of a lack of a definite and uniform nomenclature and therefore it may be well to come to some understanding as to exactly what we mean by the term "backwardness in children." No two children are of exactly the same grade, mentally, but they differ in this respect as they differ in respect to physical characteristics. The backward child, according to the common acceptation of the term, is one who is below the average intelligence of children of the same age; and for our present purposes, this is probably the best definition; but a more scientific one would make the term "backward child" mean one who is not living up to his own possibilities or capabilities. This definition, however, is in advance of the times and it will be applicable only when children receive more individual study and training and when they are not herded together like sheep, regardless of their peculiar characteristics and needs. Moreover, it will be observed that backwardness, in this paper, will be regarded as a disease. This is for the sake of convenience and not because it is in all respects deserving of so much distinction.

The diagnosis of backwardness is not difficult. All children who do not, can not or will not keep up with their classes must be regarded as backward, according to our definition, and they should have our most careful consideration.

The prognosis in these cases is not so simple, for this involves an inquiry into the causes, and some experience in the various methods of special training. We must take into consideration the inherent possibilities of each individual child and determine what his mental capacity and capabilities would be in a suitable environment and under more favorable conditions.

The object of this paper is to consider to what extent a study of the speech of children will aid us in making the diagnosis of backwardness and, more especially, in venturing on a prognosis. It may be said, without fear of contradiction, that freedom of speech is an absolute essential to the normal development of children and that any defect of speech, however slight, must make its impress on the child's mentality and prevent him from doing all that he would otherwise be capable of doing.

Not all children with defective speech, however, are thus prevented from keeping abreast of their fellows in school. Occasionally we find one with sufficient concentration and will-power to succeed, in spite of the handicap which defective speech must entail, but this is the exception and not the rule.

Speech is a tool of the mind and just as the artisan is dependent on good tools for success in his work, so is the child dependent on good speech for the normal development of his mental faculties; and just as a poor tool may be responsible for faulty work, so is defective speech oftentimes the cause of slow development or backwardness in children. Many illustrations of this fact might be given. One or two will be sufficient to emphasize its importance.

In 1895, a young man, 19 years of age, was brought to my office for a prognosis, the diagnosis made by his family physician being imbecility. He had many symptoms of this disease. He was backward in his studies, so much so that school had to be entirely given up. He could not speak, read or write intelligibly, and he was unable to spell the simplest words. His expression was vacant and staring. His lower jaw was receding and his mouth open. He was exceedingly awkward in his movements and unable to express himself in any language. His speech was wholly unintelligible. He could not give his name or his residence, and he was unable to make the conductor of the railway train understand at which station he wished to get off.

The prognosis in this case could not be made offhand. It was of the utmost importance, because on it depended the treatment and the patient's future usefulness. After careful investigation, it was discovered that one great barrier in the way of mental development was the lack of power of expression and it was manifest that until the faculty of speech could be established the man could never become a useful citizen. On the other hand, it was assumed that if the faculty of speech could be acquired, the mere effort necessary to its acquisition would serve to develop some degree of mental power. The question therefore arose as to what was the cause of the tardy development of speech. On examination it was found that the patient had a defective tongue. The genio-hyoglossus muscle was too short and bound the tongue down to the floor of the mouth and thus prevented its normal action in the processes of articulation. A simple operation was performed, which consisted in a division of some of the anterior fibers of this muscle, thereby giving a free tip to the tongue. The operation was followed by a systematic course of training for the purpose of teaching the use of the tongue and the related organs in processes of speech. A little more than a year sufficed to accomplish this result and the boy who, up to 19 years of age, was supposed to be an imbecile, is now one of the most successful real estate brokers in Philadelphia.

This case is illustrative of a large class of children who are backward, not because of any organic mental deficiency, but because they are lacking in the power of an easy and natural expression of their thoughts.

Another case was that of a lad brought to my clinic at the age of 15 because his speech was unintelligible and he was backward in his studies. Unlike the former case, however, he was able to make some progress in certain lines of school work and presented an appearance of one having greater intelligence. He had a distinct vocabulary of sounds of his own unlike any I have ever heard and it was by no means limited. He could talk and read fluently, but it was all a meaningless jumble to everyone but himself and he claimed that the substitutes he used sounded to him the same as the actual words spoken by his fellows. In other words, his ear did not discriminate between his own jargon and the normal speech of other people. He was not a robust boy. In early childhood he had some organic heart affection. He was a "blue" baby, had spasms and some difficulty in respiration. He also had web fingers on both hands. indicating arrested prenatal development.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee of the Section: Drs. H. E. Tuley, Edwin Rosenthal and Samuel W. Kelley.

This boy was backward merely because he could not speak intelligibly; because he was unable to command that important tool of the intellect, language. A few years of speech training, however, resulted in a complete change in his mental and physical processes and he is now holding an important office position in one of the departments of the University of Pennsylvania.

Many other similarly interesting cases have come under my observation, but the above two will suffice to illustrate the importance of speech as a factor in the diagnosis and prognosis of backwardness in children, and from the history of their cases we may draw the following conclusions:

1. It is not always possible to determine at a glance the cause of backwardness in children.

2. Backwardness in children is not always due to a central lesion, but may be the result of arrested cerebral development due to some abnormality of structure in the peripheral organs.

3. A very common cause of backwardness in children may be some abnormality of structure in the peripheral organs of speech.

4. So closely are the speech centers related to the ideational centers of the brain that any impairment of the one generally results in a corresponding impairment of the other.

5. The best method of arriving at even a proximately correct prognosis in cases of backward children is to apply the speech test, or, in other words, to ascertain by careful study and experiment to what extent the faculty of speech may be improved, and it will be found that in those who are susceptible to training in what may be called the refinements of speech are the ones for whom we may promise the best results, and that possibilities for general development will be proportional to the capacity for speech development.

A PLEA FOR THE BACKWARD CHILD.*

C. F. WAHRER, M.D.
FORT MADISON, IOWA.

Before treating this subject in any detail, I wish to define the term "backward child." By this I do not mean a defective child, but one whose body, as well as intellectual faculties, are all in existence, and whose parentage is not of a degenerate character, but normal, as we generally understand the term. The line between normal and abnormal may be somewhat hazy, not well defined, nor perhaps capable of exact definition, but we all somehow have a very fair conception of the expression, unless we appear as experts in a will case in court. Yet if we remember our experiences in the school room as teachers or even as fellow pupils, or make observations in schools as visitors, we do not always have this same opinion, as to the brightness or dulness exhibited by various children. Thus many a child, somewhat backward in its studies, has been condemned as a dunce or even defective, by the too hasty observer, and, in the class under discussion, all on account of a lack of perception on the part of the teacher or parent making this unfair and unjust deduction.

The fallacy of observation is due to contrast; this I wish to explain, and show that comparisons in these cases, as the old adage says, are odious. The comparison is with the so-called bright or forward child. By observation we have learned to expect a certain amount of physical and mental development from a child at a given age. If the child is unusually observant, with a good memory and the power of expression, it is called bright or even precocious, and, in comparison with suc children, all others seem more or less dull. Wher advancement is normal, we call such children norma or average and even recognize good minds. Where however, the expected progress is slow, comprehension more or less obtuse, and the power of expression limited we say such children are backward, dull, or even may imagine them defective. All this is a matter of comparison, with the bright child as our model.

The truth is, there is nothing wrong with the child He has good powers that are latent or of slow development, or is really developing in a direction different from the course intended.

For instance, a morning-glory vine twines around its support from right to left, while the hop vine twines in the opposite direction. Both are correct, and it is just as useless an effort to reverse these directions, and serves as little good purpose, as it is to make these so-called backward children follow the course of the so-called bright child.

An astronomer should not be deceived by a meteor with all its brightness and brilliancy, and make invidious comparison to the disadvantage of the pale, far-distant, fixed star, which upon study proves to be not only a sun but a whole solar system; so in like manner, we should not, after observing a bright child with good memory but of ephemeral mental development, underrate the slower, dull pupil, whose mind powers are latent, not absent and in the process of a splendid development if rightly studied, and when once made manifest, show an intellect as strong and unwavering as the fixed star.

Great men, like Shakespere, Sir Walter Scott, Edison, Beecher, Peter Cooper and many more, were condemned by their teachers and proclaimed hopeless dunces and their parents were beseeched to take them from school, as it was considered a waste of time and money to keep them there. Milton, one of the greatest poets of the theological school, was 63 years of age before he became known; according to his own saying, he appeared late, but when he did appear he was fit to do so.

While these backward children are not favorites with the average educator, it should be a teacher's duty and pride to search for the hidden talents lying dormant among children of most unprepossessing appearance. Examinations, or tests, as they are more recently called, intended for this purpose, are most dismal failures in this direction, for they reveal not the intellect or the slumbering genius, but only what a child with a good memory has stored from recently gathered facts. And let a happy manner of good expression be added and this child shows to splendid advantage over its fellows. So these tests are not tests after all, only deceptive surface phenomena, with their usual exceptions.

Neither are the cumbersome and high-pressure curricula of our schools, with their many anachronistic arrangements, calculated to advance the subjects of our contention, nor to evolve acuteness and dispatch out of obtuseness and retarded progression; nor are they in any way the least helpful in developing latent or slumbering powers. The adult life is strenuous enough without introducing this strenuous element into all phases of pre-adolescent childhood. In this line we need revision with a special view to simplification rather than complexity, and the arrangement of studies synchronous to mind capacity. But how can we maintain such a statement? Simply by past experiences, from which there are an endless number to draw.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee of the Section: Drs. H. E. Tuley, Edwin Rosenthal and Samuel W. Kelley.

For instance, these bright boys and girls who were such splendid reciters, and who graduated at the head of their classes, who furnished valedictorians and salutatorians, what has become of them? Did they become the traditional president or governor, the judge on the bench, the bishop or the eminent medical man or surgeon, master mechanic, the great commander? No, they did not! When the evanescent spark of genius first attracted our attention and its meteoric rays dazzled our eyes, we little dreamed that it was only an explosion, a big sound, a flash across the intellectual sky, and all was dark. But the steady glow of a slow but ponderous mind, groping about in the dark, as it were, to get recognition by its own light, to develop by its own evolution, may be long in accomplishing it, but when once known will make its influence felt long after the meteor has passed away and is forgotten.

The brightest diamond in the hands of a bungler becomes a mere mass of useless carbon; in the hands of a master, a diadem fit to adorn the crown of kings. So a really valuable but apparently dull mind in the hands of a superficial educator becomes a useless cumberer in the ranks of life, while under the guidance of a superior intellect, that has discovered under the seemingly unprepossessing exterior a true gem, it is so developed and its course so shaped as to evolve a mind fit to reign among the earth's greatest and best.

The responsibility of educators and parents is immeasurable, viewed in this light. To discover and guide the backward child is the duty of the hour, not to condemn and forever destroy. Our sympathies and warmest endeavors should be invoked by every child that belongs to this category, and every effort should be put forth in behalf of a class, out of whose ranks the earth's greatest geniuses have arisen and led the children of men out of the wilderness of thought into the Canaan of light and bliss.

With Gray we can say:

> Perhaps in this neglected spot is laid,
> Some heart once pregnant with celestial fire;
> Hands that the rod of empire might have swayed,
> Or waked to ecstacy the living lyre.

So it is not how early, but how well, a given person develops; not how soon he accomplishes his life work, but how effective are its results, and how great a factor it may be in the sum of existence. In this sense, it is never too late when a great mind makes its appearance. For,

> "Nothing is too late
> Till the tired heart shall cease to palpitate.
> Cato learned Greek at eighty; Sophocles
> Wrote his grand Oedipus, and Simonides
> Bore off the prize of verse from his compeers,
> When each had numbered more than four-score years,
> And Theophrastus at four-score and ten
> Had but begun his "Characters of Men";
> Chaucer at Woodstock with the nightingales,
> At sixty wrote the "Canterbury Tales";
> Goethe at Weimar toiling to the last
> Completed "Faust" when eighty years were past.
> These are indeed exceptions, but they show
> How far the gulf-stream of our youth may flow
> Into the arctic regions of our lives."

I crave a greater sympathy for the "backward child."

This symposium will be completed next week, together with the discussion.

SECTION OF OPHTHALMOLOGY.

ADDRESS OF CHAIRMAN DELIVERED AT THE FIFTY-SECOND ANNUAL MEETING OF THE A. M. A., HELD AT ST. PAUL, MINN., JUNE 4-7, 1901.

J. A. LIPPINCOTT, M.D.
PITTSBURG, PA.

The precedent established by my honored predecessors of dispensing with a review of the progress in ophthalmology is, in my judgment, a wise one. Even were one disposed to think differently, this would not be an opportune time to attempt such a résumé. For, standing as we do on the threshold of a new century, it would be incumbent on the reviewer to take note not only of the changes of a year but of the advances made in our department of medical science during the hundred years which have just passed into history. During that period thousands of distinguished workers have co-operated in building the imposing structure constituted by the ophthalmology of to-day; and of these thousands there are three to whose achievements alone many volumes of addresses might be devoted without doing justice to the theme. The names of Von Graefe, Donders and Helmholtz will be gratefully remembered long after those of their most noted contemporaries in the spheres of war and statesmanship, the favorite avenues to distinction, shall have been relegated to oblivion.

To one of this mighty triumvirate we owe the priceless gift of the ophthalmoscope which has so marvelously enriched our knowledge and added to our power to benefit mankind. This instrument has now seen fifty years of ever-increasing usefulness, a fact which is fittingly emphasized in our program and in the interesting collection of ophthalmoscopes and ophthalmoscopic literature which, through the efforts of the committee appointed for the purpose, is open for your inspection.

Other subjects to engage your attention are the methods of treatment applicable to the abnormal conditions of the extrinsic ocular muscles comprised under the terms strabismus and heterophoria—conditions which, despite all that has been written upon them, are still in many points obscure.

We shall also discuss the important problems presented by the relation of visual acuity to occupation in general and to the railway service in particular. An effort to elucidate these problems may fairly be expected of this Section, which, as a subdivision of the American Medical Association, is peculiarly representative and National in character.

In addition to these subjects we shall have the opportunity of considering a topic on which much light has been thrown by recent investigations, namely, the nature of the pathological changes produced by certain toxic agents in the retinal elements.

I need not refer specifically to other portions of the program, which is replete with variety and interest, notwithstanding the rule adopted for this meeting by the General Committee of the Association restricting the number of papers presented in each Section to thirty-five. Owing to this rule a number of meritorious articles had to be excluded. In this connection it may be remarked that many of the difficulties of your officers, especially the Secretary, might be obviated if all abstracts were handed in as early as possible. You are aware of the regulation requiring the completed program to be at the office of the general secretary in Chicago not later than May 4. It will be necessary to send it several days earlier if, as seems desirable, the Secretary of the Section is to have an opportunity to examine the proof. As a matter of fact all of the abstracts ought to be in the hands of our Secretary on or before the middle of April.

Inasmuch as the number of papers is now so limited it is highly important that as few as may be shall be "read by title." Those, therefore, who, after sending titles or abstracts, find that they can not attend the meeting should, when they can, notify the Secretary of this fact in time to permit their places on the program to be taken by others.

Allusion has been made to the wonderful development of ophthalmology during the 19th century. This development has in no inconsiderable degree been aided by the labors of our own countrymen, among the most conspicuous of whom was one who has dropped out of the ranks since our last meeting. Henry D. Noyes as a teacher was erudite without dulness, as a writer prolific without being prolix, frank and incisive in debate without ever violating the laws of courtesy—a commanding figure in any assemblage and in private life a charming companion. He and others have made the past century notable. What are we to expect of the present? Let us be stimulated by the hope and belief that the mantles "of the great ones gone forever and forever by" shall fall upon shoulders not unworthy to wear them and that "the glowing pages of the past may be taken as the sibylline leaves of the future."

LATE IMPLANTING OF GLASS BALL IN ORBIT, AND EPITHELIAL LIP GRAFTS TRANSPLANTED TO ORBIT.*

ADELINE E. PORTMAN, M.D.
Chief of Eye, Ear and Throat Department of Woman's Clinic: Assistant in Eye and Ear Department, Emergency Hospital and Central Dispensary Clinic.
WASHINGTON, D. C.

The late implanting of a glass ball in the orbit is not a new operation; L. Webster Fox of Philadelphia, and many others in other cities, have succeeded well in this line, but the operation had not been done before in Washington, D. C., and there is a feature in this I do not find in others, namely, the fastening together of the cut ends of the recti muscles over the glass ball. My first case of the kind was this:

W. C., white, aged 50, English birth, a farm laborer, received traumatism to cornea, which became infected. Several cultures were made at different times from the discharge, but were negative in results. Complete destruction of cornea ensued from neglected condition, the patient attending the clinic at intervals of a week or ten days only.

In June, 1899, the atrophied globe was removed from left orbit by Dr. Burnett, no attention being paid to the cut ends of the ocular muscles; they simply collapsed, forming with the other tissues a thick cicatrix in the bottom of the orbit, and a great amount of shrinking left a most unsightly cavity. The patient had asked to have an eye shell furnished to replace the diseased globe, before he would consent to have it removed, as his personal appearance was of great moment to himself. One large enough to in any way fill the lids was most unpleasantly staring and disagreeable in appearance; so he came back several times to repeat his request for "one that would move." That, he was told, could not be done; but still he kept coming, until one day I told him that by putting a glass ball into the orbit, it might possibly move a little. He was delighted with the idea and wished at once to make an appointment for the operation. Dr. Burnett, chief of eye and ear clinic of Emergency Hospital, consented to its being done, and kindly assisted in the work.

My operation was the following: The bottom of the cavity was opened; the conjunctiva was raised all around from the surface; the scar tissue was so far as possible removed. The cut ends of the recti muscles were carefully dissected up, and as each one was found, a suture of black silk was passed through the cut end, and it held to one side; the cavity underneath was made large enough to easily hold a large-sized glass ball. After bleeding had stopped, the opposing muscles were brought together and firmly tied over the ball, first the vertical, then the horizontal, the two knots beside each other, after which the sutures were cut short off and were never removed. The conjunctiva was closed over all with five sutures, and the ordinary enucleation dressing applied.

Reaction was very marked in this case. There was much swelling, discoloration, and oozing of fluid, enough to keep dressings wet for three or four days. The last sutures were removed from the conjunctiva twelve days after operation, and a shell was placed in twenty-four days later. To the delight of the patient, to the surprise of all who saw it, and to my great relief, it did move, making fully one-third of the excursion of the other eye.

After a few months a larger shell was used, as the tissues became shrunken, but still giving satisfactory motion instead of an immovable stare. Patient has been doing farm work of all sorts for fourteen months and ball has caused no discomfort, remaining firmly in place.

EPITHELIAL LIP GRAFTS.

Case No. 2.—K. McG., white, Irish born, aged 38, wife of laborer. In heating a tightly-closed can of coffee for husband's supper at midnight, the overheated can exploded, the stream of boiling fluid striking directly in the eye, scalding whole side of face and neck severely. The cornea sloughed off completely, the lids already badly scarred by old trachoma, contracted so much as to show the hollow behind them, making a most ghastly appearance. After the removal of atrophied globe (which was always painful) in June, 1899, Dr. Burnett did an operation in March of 1900, on the orbit, for replacing mucous membrane with skin taken from the inside of the upper arm, where it is thinnest and most pliant; they adhered only in what had been the upper ocular surface, while the lower lid was still everted, and contraction so great that the smallest shell could not be kept in place.

In September, 1900, with the assistance of Dr. Reeve, I removed the cicatricial tissue as much as possible, made the cavity fit a shell large enough to look well; I replaced the mucous membrane with epithelial lip grafts, taken from the inner side of under lip, by means of a cataract knife, without the clamp. The several strips were placed carefully over the denuded surface of lid and base of orbit, the shell put in place to keep them from moving, the lids drawn over and firmly bound up to prevent all motion possible. The lids came together easily and naturally.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

This was done on Monday; the patient returned on Thursday to have the dressings changed. There was not the slightest discharge of pus from the cavity, the mucous membrane having the appearance of always having lived there; it was redressed the same as before. On Friday the patient, to have her children go to school clean, did some washing of their clothes, which from the motion partly displaced one of the strips, and on Monday the loose end was cut off.

She wore the shell night and day for two months, removing once a day to cleanse the orbit. It was then replaced by a larger one; for she came back with the long axis placed vertically, it having dropped out when left in the correct position. A much larger shell was then used, the lids closing easily over it. She does the housework for a family of seven, and still wears it with comfort. The epithelium from the skin placed in the orbit causes the most of the difficulty of cleanliness.

September 3, 1901.—This patient still wears the same shell with perfect ease at the present time, one year after the operation.

Clinical Report.

CASE OF PRIMARY SYPHILITIC LESION OF THE FAUCIAL TONSIL.

GEORGE C. STOUT, M.D.
PHILADELPHIA.

The patient, a young lady, unmarried, of good family history, and apparently of good moral character, was referred to me on Sept. 18, 1900, by my friend, Dr. E. K. Perrin.

Her physician stated that she had had an obstinate "sore throat," for which he had administered the usual remedies for follicular tonsillitis, during the past week, with the result that the condition was increasing in severity rather than improving.

The patient dated the onset of her trouble five weeks prior to my examination. She said that she had then taken a surf bath while unwell, from which she caught a severe cold, with headache and muscle pains which lasted for about three weeks, when it "all seemed to settle in her throat."

For a week past she had been unable to swallow any solid food, and could take liquid nourishment only with the greatest difficulty, and for the past two days was unable to take any nourishment whatever, on account of the excessive pain during the effort to swallow.

She had been able to sleep but little during the last two weeks, and although she had been a healthy, robust girl a few weeks ago, she was now the picture of physical distress.

Her color was pale and her expression anxious. Examination of the fauces disclosed very large tonsils, which were congested and angry. The right side was the larger; it was ragged and upon its surface was an ulcer extending from pillar to pillar. This ulcer was nearly level with the surface, and was covered with a thick, grayish membrane, for which there was little secretion.

The left tonsil was swollen and its crypts contained the yellowish detritus so often seen in sluggish tonsils. The pain upon pressure seemed to involve the surrounding parts, as well as the tonsils themselves.

For the three days following her first visit her temperature varied from 99.2 to 100 in the mornings, and from 100.2 to 102 in the evenings. At the first visit she was treated tentifly, her throat being thoroughly cleansed, and a 15 per cent. solution of nitrate of silver was applied to the ulcerated surface; there was no improvement from this treatment, or from the home treatment prescribed.

Upon her second visit, a rash, which was but faintly visible at the first visit, was very evident over her forehead, body and limbs, and the specific nature of the disease was suspected, especially as there was some enlargement of the right cervical glands. She was then placed on 40 grs. of potassium iodid daily and a solution of 1 to 1000 bichlorid was applied to her throat. She had great difficulty in swallowing the iodid solution, but there was some improvement in her condition after this treatment.

On September 24, as the diagnosis was fairly certain, she was given ½ gr. of bichlorid of mercury, hypodermically, and 40 grs. of the iodid daily.

Two days later there was a decided improvement in her general condition; the eruption on her body and face had dried up for the most part, and her throat was so much improved that she was able to eat a soft-boiled egg, which was the first food, excepting milk, she had been able to swallow for three weeks.

On September 29, she was given another hypodermic of bichlorid (gr. ¾), and by October 1 the ulceration on the tonsil had disappeared, and while her tonsils were somewhat enlarged her throat no longer annoyed her, and she was able to sleep through the night and take proper nourishment.

On account of the evident innocence of the patient, and in deference to her surroundings, it was thought unwise to question her as to the possible source of contagion. Her physician, who had known her for some years, feared that she might do herself some personal violence if she suspected the true nature of her trouble; therefore, in the absence of a definite history, it was thought well to confirm the diagnosis by the therapeutic test.

When her condition was nearly normal and she was able to sleep and take proper nourishment, the anti-syphilitic treatment was withdrawn (October 10), and she was simply kept under observation.

In two weeks' time, after she had remained away several consecutive days, against our advice, the skin lesions had broken out anew, over her whole body, and two mucous patches were found on her right tonsil, and three on the left; the appearance of the throat, however, being entirely different from that of the first visit. The hypodermic injections were then renewed in large doses (½ gr.), and 30 grs. of the iodid were given daily.

As all visible lesions improved within a week, and have now nearly disappeared, the diagnosis is confirmed, and the future course of treatment is determined. While the cause of the infection could not be positively determined in this case, the circumstantial evidence all pointed to an innocent inoculation, probably from the caresses of one who had secondary lesions in his mouth. The stratified squamous epithelium which lines the mouth and fauces affords excellent protection against germs entering the system at these points. The ragged hypertrophied tonsil in this case rendered the fauces more vulnerable; the cells lining the tonsil crypts were probably soaked by cheesy detritus and desquamated by hawking and "clearing the throat," thus exposing the underlying structures and affording an excellent soil for the virulent specific germs.

The case above related occurred in the right tonsil, which is the more commonly affected in these conditions. There have been more cases reported of chancre of the tonsil in men than in women.

Sex Determination from a New Point of View.—Flammarion has been studying, since 1894, the action of the solar rays on the life of plants and animals. He announced at a recent meeting of the Paris Académie des Sciences that he had found the normal proportion of males born among silk-worms was very much increased if the worms were kept in darkness or under dark-colored glass. Under light-colored glass the normal proportion of 50 per cent. was maintained, but under dark-colored glass the proportion increased to 68 per cent. He also found that the proportion of males was increased still higher if the worms were insufficiently fed. Even under light-colored glass, on insufficient food the males averaged 78 per cent. He queries whether this latter fact may not indicate that the effect of the dark-colored glass is merely to diminish the appetite and thus cause insufficient alimentation.

SATURDAY, OCTOBER 12, 1901.

THE PREVENTION OF THE SPREAD OF PULMONARY TUBERCULOSIS.

The demonstration by Flügge and his pupils in Breslau, and also by others, that tubercle bacilli are disseminated in fine sputum particles during the talking, coughing and sneezing of phthisical patients and the fact that guinea-pigs may be rendered tuberculous by exposing them to the coughing of the consumptive, have led to the belief that the dissemination and inhalation of droplets of sputum laden with bacilli may be one of the most important methods of spreading pulmonary tuberculosis. Of course the same method undoubtedly obtains in other diseases also, such as leprosy, influenza, the pulmonary form of pest, etc. Recently several new investigations along these lines, but with the special object of teaching us something practical with respect to the prevention of tuberculosis, have been published from Flügge's laboratory.[1] Investigation by Heymann has shown that the dust which results from dried sputum is comparatively coarse, and for that reason endowed with a rather brief infectivity, the most dangerous because lightest and therefore carried the furthest being shreds and threads of handkerchiefs and cloths, especially when moistened with only small quantities of sputum. Naturally handkerchiefs should be disinfected frequently, say after being used twenty-four hours. Paper handkerchiefs, which can be burned when used, are especially recommended. In Cornet's celebrated investigations concerning tubercle bacilli in the dust of rooms occupied by consumptives the material was gathered by means of moist sponges, which would take up adherent masses of sputum that had been deposited directly and not by transport in the air. Heymann's investigations indicate that even in neglected consumptives' quarters the dust that forms is not at all everywhere infective and that when gathered by means of wet sponges a much larger proportion of the guinea-pigs injected become tuberculous than when swept together with a fine dry brush. But in factories, railway carriages and street cars the shaking might set in motion even the larger particles, and new researches are planned to cover the special conditions here found.

The Breslau investigators formulate the rule that during coughing the consumptive should be at least arm's length removed from other persons and he should hold his handkerchief before his mouth. In offices and working rooms the distance between the heads of the occupants should be at least one meter. This rule is based upon actual demonstrations of the dissemination of bacilli-laden particles during coughing. And after coughing it does not seem that the particles settle immediately, but may remain floating for some minutes at least. Plates exposed to the spray from coughing were found sterile after three days when kept in the light, but contained virulent tubercle bacilli even after eighteen days when kept in the dark, thus showing again the bactericidal action of light. While there seems to be no question but that masses of bacteria are hurled out from the mouth especially in coughing, yet it might be doubted that such bacteria are actually inhaled by persons standing about naturally. Nenninger, however, found prodigiosus bacilli in the basal parts of the lungs of guinea-pigs subjected for half an hour to an atmosphere into which a spray of a suspension of this bacillus had been thrown. This demonstration would seem to throw doubt upon the generally accepted statement that the normal lung as a rule is free from bacteria. And the important bearing of these various observations upon autoinfection of consumptives should not be lost sight of.

The points briefly touched upon may serve to indicate that much, very much is to be accomplished for the prevention of tuberculosis by following the indications that are derived from careful, experimental and other studies of the dangers associated with the sputum, both moist and dry. The people in general must be educated and instructed in these facts and their significance. As long as we have such a rich chance to attack the bacillus of tuberculosis directly let us not seek rest from the great responsibility in vague theorizations concerning special disposition of tuberculosis, etc. In the larger cities of this country much is being done to lessen the manifest evils of promiscuous expectoration. Attention must now be paid to what may be called the hygiene of coughing.

THE INFREQUENCY OF PRIMARY MALIGNANT TUMORS OF MIXED TYPES AND ITS BEARING ON THE CANCER QUESTION.

The many recent and valuable discussions of the cancer question, notably Senn's comprehensive review in a late number of this journal, Park's exposition of the parasitic theory in THE JOURNAL,[1] and C. P. White's[2] amplification of Ribbert's theory of tissue tension, omit one important feature in the biology of malignant tumors, namely, the rarity with which the epithelial and mesoblastic types of malignant growths occur together. This fact, however, is of much importance. In his report of a primary tumor in the thyroid gland of a dog, which was composed of an intimate admixture of the two types, H. G. Wells[3] states that his search of the literature revealed but seventeen cases in which it was demonstrated with reasonable accuracy that a single individual presented simultaneously an independent carcinoma and an independent sarcoma. This does not tend to support the assumption of White that the general condition of the patient is of importance in determining that local disturbance of equilibrium, which he argues would lead to tumor growth; for, if any general condition were responsible it would be reasonable to look for a much greater frequency of multiple malignant tumors. Wells found further only three cases in which it appeared probable that a primary tumor consisted of both sarcomatous and carcinomatous elements, and in all three the site was the thyroid gland. In one of these cases some of the secondary growths were purely sarcomatous, some purely carcinomatous, and some resembled the primary tumor in containing both types of tumor.

[1] September 14.

[2] Jour. Path. and Bact., 1901, vii, 339.

[3] Ibid., p. 356.

From the point of Cohnheim's theory we are justified in the expectation that mixed tumors would be frequent, perhaps the rule, because most of the "embryonal matrices," containing epithelial cells, also have a fibrous framework; yet the stroma of adrenal tumors, arising from misplaced adrenal tissue in the kidney, has not been found to assume sarcomatous appearances. Perhaps the renal tumors of mixed structure, the so-called embryonal adeno-sarcomas of the kidney, which contain not only epithelial and connective tissue elements, but also muscle fibers, might be cited as an exception to this statement. Embryonal adeno-sarcoma of the kidney, however, owes its malignancy wholly to the sarcomatous portions, the epithelium never taking on malignant, infiltrating properties. These tumors demonstrate that all of the structures of the fetal kidney may develop simultaneously into tumor, but epithelium and stroma do not become malignant at the same time.

Turning now to the parasitic theory of tumors, we find that, no matter what the nature of the parasite is thought to be, whether protozoic or vegetable, the ideas vary as to the way in which the parasites operate; because some investigators hold that carcinoma and sarcoma are due to a single organism, which causes a carcinoma when infecting epithelium and a sarcoma when infecting connective tissue, while others think that the organism of sarcoma is different from that of carcinoma though the two may be closely related. Now if the same organism were capable of causing carcinoma and sarcoma it would be reasonable to expect that it would frequently set up proliferation in both tissues at the same time and that mixed sarcoma and carcinoma would be common, which is contrary to fact. If the organism of carcinoma is different from that of sarcoma, single tumors would be the rule. Of course mixed infection with the hypothetic organisms might occur, either from the beginning, or from the implantation of one upon the other as is the usual order of things in mixed infections with ordinary pathogenic parasites. This idea agrees better, therefore, with the comparative rarity of mixed malignant tumors.

The question of cellular specificity may be referred to also in connection with this matter. If each cell did not produce its own kind mixed tumors of malignant character should be common. The infrequency of such growths bears out the doctrine of the specificness of the cells. In the case described by Wells he found no evidence of the transformation of epithelium into sarcoma cells, or conversely.

MEDICAL ORGANIZATION AND THE PUBLIC.

The objects of organization of the medical profession are not selfish ones. While some of these objects look to the well-being or the material interests of the profession in many ways, there are others which are for the good of the people also. The fight to be waged against quackery, charlatanry and pretenders, and for better education and higher standards of qualifications for entrance into the profession, itself, is not with the idea of simply bettering that profession, but for the protection of the people as well. Some of the objects to be obtained by organization are of direct advantage to the people and not even indirectly to the profession. Some of these are better sanitary laws, legislation for the prevention of disease, for the control of epidemics, and for the "enlightening and directing public opinion in regard to the broad problems of state medicine." The profession has nothing to hide or to be ashamed of in this work of organization, but, on the contrary, everything to be proud of and to willingly submit openly, candidly and freely to an intelligent public.

It is most gratifying to find in one of the solid monthly magazines[1] an article in which the objects of organization and the plans on which organization is to be effected, are elaborated. It is especially gratifying because the magazine in question admits to its pages only articles of merit and on important topics. It is written by Dr. P. Maxwell Foshay, of Cleveland, who was one of the members of the Committee on Reorganization of the American Medical Association, and who is now Secretary of the Ohio State Medical Society and doing effective work in organizing his state on the plan outlined.

In this article he shows that the attitude of medicine toward the world is very different from that obtained when medicine was encumbered by superstition, ignorance and charlatanry, much of which has been swept away by the recent developments of rational medicine. The ideal of modern medicine is the prevention of disease, and it therefore follows that the profession desires to be understood and be aided by an enlightened public intelligence. He calls attention to the new school of medicine as described by Dr. Reed in his presidential address at St. Paul, refers to the report adopted at the last meeting of the American Medical Association, and outlines the general scheme of organization. Such contributions read by an intelligent laity can not but help in the great work. We wish we might see more of such articles and on topics that are now discussed only in medical journals, but which, if presented in the lay journals in an intelligent manner and by the right men, would be the means of making the profession less misunderstood than is now the case.

---

[1] The Organization of the Medical Profession: The Forum, October, pp. 166-171.

THE TRAINED NURSE AND HER POSITION.

Dr. Malcolm Morris used to call the trained nurse a parasite upon the medical profession. The usual idea conveyed by this term is hardly the one he intended. What he meant was that her position is, what she sometimes forgets, a purely ancillary one and that her useful existence is dependent upon the medical profession. It is hard, however, for any of us to be duly humble; the trained nurse is as liable to have her conceit enlarged as anyone, and, under the adulation she receives, perhaps more than some. A very useful class of persons as a whole may, therefore, produce specimens that remind one of the objectionable kind of parasites that bite their hosts and benefactors. One is reminded of this by a recent address given before a nurses' convention, in which the speaker, a hospital head nurse or superintendent, after reviewing some well-known defects of political hospital management, for which, in spite of what appears to be the implication, the medical profession can not be held to be generally or largely responsible, she indulged in certain disparaging remarks and insinuations against physicians. She expressed, for example, a belief that the objections to the dispensary abuse only comes from men who are incompetent and lazy, and reiterated the venerable chestnut that physicians are by nature and training unfit for administrative duties.

As this is the main argument of those who keep up the real abuses she mentioned, her good judgment or her sincerity seems questionable. Her views, it is said, were shared and endorsed by others of her occupation, and, from the newspaper reports, the general temper of the convention seems to have been reflected by her remarks. It is unfortunate should nurses' organizations breed this sort of thing, and that those who ought to be a valuable assistance in the care of the afflicted should injure their usefulness by self-overvaluation.

Another instance of bumptiousness on the part of nurses, and one or two internes as well, is afforded by the very free criticisms of the medical treatment of our late President as reported in a Chicago paper. If they are not misquoted they were very free in their remarks, criticising the medical attendants of the late President both directly and by implication, the criticisms being such as might be expected from those whose limited knowledge qualified them in their own opinion to pass judgment upon men of national and cosmopolitan reputation. It apparently did not occur to them that as nurses and assistants there might be an impropriety in their expressing opinions from a distance on the surgical or medical treatment and that by leaders in the profession. The usefulness of the nurse is and always will be gauged by her faithfulness as a subordinate intelligently carrying out the directions of the physician, and it will be impaired or lost altogether if she indulges in public or even private criticisms of her professional superiors.

THE QUACKS OF BERLIN.

According to the *Medical Press and Circular*, the official records of the city of Berlin show that 60 per cent. of the quacks there prospering have been ordinary day-laborers before they blossomed out as professed benefactors of the afflicted, that only 40 per cent. have had an elementary common school education, and that of the female contingent about 58 per cent. have been servant girls. Nevertheless, it is probable that they have their share of the practice among the wealthy and *soi disant* cultured classes, and, as the irregulars here claim for themselves, "pull silver doorknobs" perhaps almost as much as better qualified practitioners. We conjecture this because human weakness is not a matter of national boundaries, and Germans are, according to our observations, no more sensible as regards medical impositions than other nationalities. Another interesting fact also related is that about 30 per cent. of the Berlin quacks have criminal records—we suppose this is apart from their medical careers—and yet they thrive.

LAY CONTROL OF CHARITIES.

The beauties of patronage and exclusive lay control are illustrated by a news item that comes to us from over the water. The Duchess of Sutherland it appears has established a home for crippled children, a useful charity over which she evidently retains the supervision. A staff of doctors have until lately given their attention to the medical needs of the inmates, but very recently the titled patroness or proprietor of the establishment has introduced an hereditary bonesetter to treat them. The medical staff naturally have objected, and what the result will be has not thus far been revealed. The Duchess is herself apparently so well satisfied with the bonesetter that she insists upon his retention, and doubtless, after the manner of the laity, considers the physicians altogether in the wrong for refusing to co-operate —if that is the word—with him. It would seem, aside from the professional point of view, that the opinion of some half dozen reputable, educated physicians, giving their services gratuitously, ought to count against that of a single uneducated manipulator, but that is apparently not the case. The medical and surgical treatment of the patients was, therefore, left to the bonesetter, whose skill and success where the doctors fail is vouched for by the Duchess. She will probably in the end come out a wiser woman, but in the meantime somebody is liable to suffer and she and her friends will only blame the doctors.

RELATION OF TAXATION TO TUBERCULOSIS.

A French physician has in a recent paper traced a direct connection between taxation and tuberculosis. He finds that the mortality from this cause is very much higher in France than in England, in spite of the climatic disadvantages of the latter country, which with its damper and foggier seasons might be supposed to favor the disease. He accounts for the difference by the better nourishment of the Englishman. The Frenchman is handicapped by excessive taxation, which makes the cost of living high and restricts the poor to bad and insufficient food. In Paris the matter is made worse by the "octroi" laws which make living there much more costly than in its immediate suburbs. All this is due to the costly militarism of continental European states; it is a penalty they pay for distrusting and hating each other. When Great Britain in the early part of the last century suffered similarly from unwise and excessive taxation, with its corn laws and its window tax shutting out light and ventilation, its mortality was also high, and the improvement in public health has followed tax reform. While we can not get our statesmen to study medical and sanitary matters we should as a profession see that they do not sin ignorantly in these ways. There is hardly a question that arises in government or politics that has not a possible medical bearing or on which medical science can not throw some light. What we pay for lack of this can not be told, but it is surely often a heavy price and may entail disaster. Public medicine in this wider sense in its relations to economics, legislation, and the like, is a field that is well worth cultivation. At present its importance is too little appreciated by our lawmakers and it is our duty as a profession to do what is in our power to enlighten them.

THE QUESTION OF SPECIALIZATION BY UNDERGRADUATES.

The field of medical practice has grown so large that no ordinary person can successfully traverse it all. Specialization is thus the result of a naturally evolutionary process, tending to greater refinement and precision in knowledge, as well as in diagnosis and in treatment. To be a specialist of the highest type, however, one must have a broad and deep foundation in general knowledge. This, however, does not imply that a tendency to specialization should not be encouraged early, providing this is not done too exclusively or to the detriment of general training. The view of the specialist should be not less broad than that of the generalist. the only excuse for the existence of the former arising from the fact that in addition to his general knowledge and ability he possess some special knowledge and ability. If, therefore, the medical student, by means of personal preference, personal endowment, or personal opportunity, chooses to devote himself in later life to a special field of medical practice, we think he may wisely devote special attention, even during his medical or collegiate course, to studies in and collateral to that department, not neglecting, we repeat, faithful attention to the other departments. In general, however, it may be stated that it were better for the ordinary student to confine himself to the broader and more general education. Medicine is a somewhat indivisible entity, its subdivision into branches being rather factitious, and no person is a secure practitioner in any one of its parts who has not a fundamental familiarity with all of its parts; therefore, he will be the best specialist who has mastered well the general field of medicine.

Medical News.

CALIFORNIA.

Smallpox is still in evidence in Oakland. Three new cases were discovered on September 27.

Santa Ana Hospital.—A movement is well under way for the establishment of a cottage hospital at Santa Ana, to cost $10,000.

Doctors Must Register.—The Los Angeles city council passed an ordinance September 30, requiring all physicians and surgeons to register at the health office and present the certificate previously obtained from the State Board of Health.

French Hospital Training School.—The French Hospital Association, San Francisco, has approved the proposition to maintain a training school for female nurses with a maximum of 35. It also authorized the expenditure of $17,000 for additions and improvements to the hospital building.

GEORGIA.

The Medical College of Georgia, Augusta, held its seventieth annual opening exercises, October 1. Dr. James M. Hull made the introductory address.

Public Schools Closed.—On account of the prevalence of scarlet fever in Eatonton and in Putnam County, the public school has been closed for one month. The public shools of Rome have been ordered closed for two weeks on account of scarlet fever.

Personal.—Dr. Gustavus G. Roy, Atlanta, will spend the winter in Florida on account of ill health.——Dr. Charles H. Hall has been elected Chairman of the Macon Hospital Medical Board, vice Dr. William F. Holt, deceased.——Dr. Evan Park Howell, Atlanta, has been appointed assistant surgeon in the Army with the rank of first lieutenant. He is now in the Philippines.

ILLINOIS.

New Cottage Hospital.—The new addition to the Peoria Cottage Hospital will be opened for patients, November 1. The attending staff for the year consists of Dr. John D. Miller, president; Dr. Thomas M. McIlvaine, vice-president; Dr. Otho B. Will, secretary; Drs. Paul Dombrowski, Emerson M. Sutton, Robert W. Baker, Robert A. Hanna, Elmer M. Eckard, Frank B. Lucas, Oliver J. Roskoten, Sumner M. Miller, John C. Roberts and Harrison Steele.

Personal.—Dr. Frank R. Pitner, Clay City, who is in his ninetieth year and has been practicing medicine since 1839, has gone to California for the winter.——Dr. Samuel Moore, Danville, has moved to Jamesburg.——Dr. Fred W. Carman, Prophetstown, has sold his practice and will locate in Geneseo.——Dr. Emma Morgan, Aledo, has opened an office in Rock Island.——Dr. E. L. Birch has resigned from the staff of the Illinois Eastern Hospital for the insane and will locate in Robinson.——Dr. Henri S. Babcock, Jamesburg, has located in Danville.——Dr. Frank W. Goodell, Effingham, has been reappointed lecturer on anatomy at the College of Physicians and Surgeons, St. Louis.——Dr. J. A. Guertin, L'Erable, has moved to Clifton.

Chicago.

Dr. E. C. Dudley has resigned the chair of gynecology at Northwestern University Medical School.

Dr. Albert P. Ohlmacher has returned to Chicago and has succeeded to the chair of pathology in Northwestern University Medical School made vacant by the resignation of Dr. Gustav Fütterer.

St. Ann's Hospital for Consumptives.—The cornerstone of St. Ann's Hospital for the treatment of consumptives at North 48th avenue and Division street, will be laid by Bishop Muldoon, October 20. The fund thus far subscribed amounts to $23,118.

Mortality and Morbidity.—The mortality for the week ended October 5, was 419—an annual death rate of 12.41 per 1000. The Health Department still urges care in the use of hydrant water for drinking purposes, as the typhoid fever mortality continues abnormally high. There is a general increase of contagious diseases, but the type of all—and especially of scarlet fever—is mild and the mortality thus far is unusually low.

Cook County Hospital.—Drs. Arthur R. Edwards and James B. Herrick have resigned from the Executive Committee.

The president, Dr. Denslow Lewis, has appointed Dr. E. Fletcher Ingals to represent Rush Medical College, and Dr. Robert B. Preble to represent the Northwestern University Medical School. The Committee elected as chairman, Dr. William E. Quine, who appointed the following subcommittees: Clinical instruction, Drs. Baldwin and Webster; records, Preble and Lewis; morgue, MacKellar and Kearsley; admission and assignments of patients, Lewis and Swan; internes and nurses, Ingals and MacKellar; laboratory, Kearsley and Baldwin; the chairman, ex-officio member of all committees.

Resolutions in Memory of Dr. Jones.—The medical staff of St. Luke's Hospital, at a meeting held October 3, passed the following resolutions in memory of the late Dr. Samuel J. Jones: Resolved, That the medical staff of St. Luke's Hospital have heard with deep regret of the death of their confrère, Dr. Samuel J. Jones. They especially desire to acknowledge his long and faithful services to the Hospital, both as attending and consulting ophthalmic and aural surgeon, and to place on record their appreciation of his devotion to the best interests of the institution. Be it further resolved, That the members of the staff attend the funeral of Dr. Jones in a body, and that copies of these resolutions be forwarded to his nearest relative and supplied to the medical press.

INDIANA.

Smallpox in virulent form has broken out in Michigan City. Four cases had been reported up to October 3, with one death.

Anti-Expectoration in Logansport.—The city council passed an ordinance October 2, prohibiting expectorating on the sidewalks of the city.

Epworth Hospital.—The new Epworth Hospital, South Bend, was opened for patients October 7. It is a fireproof, three-story brick and stone building and was erected at a cost of about $70,000.

Personal.—Dr. James A. Turner, Martinsville, has moved to Nashville.——Dr. William E. Kessinger, Worthington, has returned to Sandborn.——Dr. Edwin M. Trook, Marion, now serving in the Philippines, has been promoted to captain and assistant surgeon, U. S. Volunteers.

Osteopaths to be Prosecuted.—The State Board of Medical Examination decided September 24 that all osteopaths who have not applied for licenses by November 1, or those who have applied and been refused licenses and are still practicing, will be prosecuted. The board granted licenses to twenty-nine osteopaths and refused five.

MAINE.

Bar Harbor Hospital trustees, at their annual meeting, decided to take steps to enlarge the hospital, and appointed Dr. R. S. Dorsett, pathologist.

Personal.—Dr. E. O. Challis has moved from Woodfords to Gorham.——Dr. Goodspeed has moved to Fairfield and will office with Dr. Ivory P. Tash.——Dr. Charles S. Knight, Bangor, has located in Woodfords.

New Licensees.—At a special session of the State Board of Examination and Registration, held in Portland, August 1, Dr. Robert Abbe, New York, and four other applicants passed their examination and were granted licenses.

MARYLAND.

Baltimore.

The College of Physicians and Surgeons opened September 30 with an introductory lecture by Prof. William F. Lockwood.

The new infectious diseases hospital will have four separate buildings; an administration building, one for scarlet fever, one for measles and the fourth for diphtheria.

Maryland Medical College.—Dr. W. McLean Yost has been appointed associate professor of materia medica and clinical diagnosis and Dr. P. Eugene Craig associate professor of diseases of children. This school is reported to have begun its its session with 106 matriculates.

Class Meetings.—The first weekly meeting of the fourth-year class of the Johns Hopkins Medical School was held at Dr. Osler's residence October 5. At these meetings, which were inaugurated by Dr. Osler, the members of the class report cases seen and studied in the hospital and patient department.

Woman's Medical College Changes.—The following changes have been made in the faculty of Woman's Medical College, Baltimore: Henry P. Hynson, Ph.G., has been elected to the chair of pharmacy, with H. A. B. Dunning, Ph.G., as assistant: Dr. Frances A. Carpenter has been appointed lecturer on embryology; Dr. W. S. Skillman, lecturer on diseases of the stomach; Dr. Louise Erich, lecturer on orthopedics, and Dr. Henry W. Kennard, demonstrator in anatomy.

City Hospital Staff Changes.—Drs. Louis Stick, Louis J. Rosenthal and Albert Conrey of the staff of the Baltimore City Hospital, have resigned on account of disagreement with the faculty of the College of Physicians and Surgeons, regarding the regulation of the hospital. Dr. F. M. Owens has been appointed resident physician; Drs. Frank T. Marr, J. C. Sullivan, H. B. Jester, and E. T. West, have been advanced; and Dr. W. E. Smith has been appointed a member of the house staff.

Personal.—Drs. Francis T. Miles and L. Wardlaw Miles have returned after spending several months in Europe.——Dr. John Ruhrah, who has been spending the last 18 months in special studies in Vienna, Berlin, Paris and London, has returned and will take part in the instruction at the College of Physicians and Surgeons this winter.——Dr. Henry B. Thomas has returned from the Blue Ridge Mountains.——Dr. Henry M. Hurd, Superintendent of the Johns Hopkins Hospital, has returned from a trip to Nova Scotia, Buffalo and the North.——Dr. A. V. Cherbonnier, U. S. Army, is convalescing at the Presbyterian Eye, Ear and Throat Hospital from an operation on his right eye.——Dr. J. A. Gale, Roanoke, Va., is at the Johns Hopkins Hospital with septic poisoning due to infection of the third finger of the left hand, while performing an operation about three months ago.——Dr. Osler during the summer visited Amsterdam and there ordered a large number of books, including some valuable editions of medical classics, for the library of the Medical and Chirurgical Faculty.

MASSACHUSETTS.

Dr. Octavius T. Howe, Lawrence, who has been district medical examiner for seventeen years, has resigned.

Diphtheria is increasing in Lowell to an alarming extent. Seven cases were reported to the health board, October 1.

The Albert Bowman Wood Surgery, which is to be erected at Memorial Hospital, Worcester, by Mrs. Wood, is to be a two-story building, 47 by 60 feet, with two operating rooms and all modern appliances. The building is to cost $20,000.

Personal.—Dr. T. H. Grady, Clinton, is about to locate at Maynard.——Dr. Joel Boyer, Oatdale, has moved to Easthampton.——Dr. J. Frank Hall, Lowell, has passed the Army Medical Board examination and has been commissioned first lieutenant and assistant surgeon, U. S. Army.——Dr. Hiram H. Burns, Athol, has sold his practice to Dr. Oliver A. T. Swain, Washington, D. C.

MICHIGAN.

Smallpox is reported from Shiawassee County. The patient is a school teacher who, although ill, continued to teach for several days.

Dr. Beverly D. Harison, Sault Ste. Marie, has been appointed a member of the State Board of Registration in medicine for a term of four years from October 1.

Personal.—Dr. Henry B. Landon, Bay City, has been reappointed a member of the State Medical Board.——Dr. A. A. Spoor has decided to locate in Bay Rapids.

New Medical Building.—The cornerstone of the new Medical building of the University of Michigan, Ann Arbor, will be laid October 15. Dr. John A. McCorkle, Brooklyn, of the class of 1873, will deliver the address.

MINNESOTA.

State Examination.—At the examination for license to practice medicine in the state, held in St. Paul, October 1, 2 and 3, 26 candidates appeared, 3 of whom were women.

Hospitals to be Built.—Building permits have been issued for the completion of the Swedish Hospital, Minneapolis, to cost $35,000, and for the third story of the contagious disease building at the Minneapolis City Hospital, to cost $5000.

Personal.—Dr. Paul D. Cook has been appointed assistant police surgeon of St. Paul, vice Dr. W. G. Richeson, term expired.——Dr. James P. Davis has moved from Millville to Kellogg.—Dr. H. C. Stuhr, St. Paul, has located in Crookston.

Diphtheria.—Health Commissioner Hall, of Minneapolis, blames the local profession for the fact that there are now 400 cases of diphtheria in the city. He says there are dozens of physicians who never send for culture tubes, and ignore the law compelling them to report contagious cases. Malignant diphtheria is said to be raging north of Preston.

Smallpox and Vaccination.—At White Earth Reservation, no Indian is allowed to receive his fall payment until he has been vaccinated.——Strict quarantine is maintained at Mille Lacs by the Indian police.——Dr. Henry M. Bracken, Minneapolis, of the State Board of Health, says that it would be easy to stamp out contagious diseases if there were no railways. He has written to the State Superintendent of Public Instruction, remonstrating against his position that school authorities can not exclude from school children that have not been vaccinated unless an epidemic of smallpox is prevalent or threatened. He holds that there is practically an epidemic of smallpox in the state and that vaccination should be compulsory. He cites that 6288 cases of smallpox were reported up to August 12, since the disease appeared in the state, and that 122 new cases were reported during the last fortnight.

MISSOURI.

Personal.—Dr. P. H. Stultz, Cedar Canon, has located in Pawnee, Okla.——Dr. Owen P. Farrington has moved from Springfield to Louisiana.

Leper and Nurse Isolated.—Dong Gong, the Chinese leper, of St. Louis, and Dr. Louis Knapp, his volunteer nurse, have been installed in the isolated house built for them near the isolation hospital.

Scarlet fever is prevalent to an unprecedented extent in Kansas City, and the city physician, George O. Coffin, says physicians aid the spread of the disease by not reporting cases to the Health Department. He promises to have derelictions of this kind severely dealt with in the future.

MONTANA.

State Examination.—The State Board of Medical Examiners met at Helena, October 1 and 2, and examined 27 candidates, including one woman and two Chinamen.

Sanitary Rules.—The Fergus County Board of Health has adopted a sanitary code which provides for location and cleansing of vaults; disposal of offal; prohibition of sale of diseased food; compulsory vaccination of school children; closing and disinfection of schools when cases of infectious disease occur; report to the Board of cases of contagious diseases; prohibition of public funerals in case of contagious disease, and closure of schools during epidemics.

New Hospitals.—The National Croatian Society expects to build a hospital in Anaconda to cost $20,000. The society has 20,000 members in Montana.——St. Luke's Hospital, Livingston, will be opened November 1. The additions to St. John's Hospital, Helena, are nearly completed and it is expected that the institution will be ready to receive patients, November 1.——Helena architects have been invited to submit competitive plans for the new St. Peter's Hospital to be erected at a cost of $45,000.

NEW MEXICO.

St. Joseph's Hospital.—An institution fully equipped for the treatment of tuberculous invalids has been established at Silver City under the care of the Sisters of Mercy. Dr. Earl S. Bullock, formerly pathologist and physical diagnostician, U. S. General Hospital for Tuberculosis, Fort Bayard, is medical director, and the consulting physicians are Major Daniel M. Appel, Surgeon U. S. A., Commanding U. S. General Hospital, Fort Bayard, N. M., and Drs. Will T. Williams, E. L. Woods, and Samuel M. Lane, Silver City.

NEW JERSEY.

Passaic General Hospital.—Owing to the failure of the citizens of Passaic to come to the aid of the General Hospital Association, the hospital will be obliged to close Jan. 1, 1902. There are now nearly one hundred patients in the hospital, about two-thirds of whom are free.

Endorsement of State Board.—The State Board of Medical Examiners of Maine has recently followed Delaware and other states in endorsing the certificate of license issued by the New Jersey Board. The effort of the New Jersey Board to extend the limits of interstate reciprocity is meeting with appreciation.

September Examination.—At the September examination of the State Board of Medical Examiners 35 candidates were examined, of whom 8 were rejected, making the percentage of rejections 22.8. Dr. Samuel Henry Sulouff, of Christ Hospital, Jersey City, graduate of the University of Pennsylvania, attained the highest average of any during the year.

Medical Inspection of Schools.—The Newark Board of Education has provided for a daily medical inspection of schools. The city has been divided into twelve districts and the medical inspectors appointed are Drs. Rudolph Braun, G. L. Warren, S. Schaeler, Winfield S. De Vausney, Frank S. Gordon, Carl H. Wintsch, M. R. Whitenack, Isabel M. Geddes, G. J. Holmes, Max Feldman, H. A. Scheppach and William Bleick.

NEW YORK.

Pest-House Burned.—By order of the local board of health the isolation hospital built at Inwood during the smallpox epidemic has been burned.

The President's Case.—The current number of the *Buffalo Medical Journal* contains a graphic illustrated description of the case of President McKinley. The account of the operation is given by Dr. John Parmenter, who assisted at the operation, and the details of the case are given by Dr. N. W. Wilson, who was the recorder at the operation.

Conference of Sanitary Officers.—The first conference of sanitary officers, including local health inspectors and registrars, will be held October 24 and 25, under the auspices of the State Health Department, of which Dr. Daniel Lewis is the head. The conference, which will hereafter be held annually, will be attended by over 1000 health officers. The object of this gathering is to present subjects of practical interest to health authorities by addresses and discussions.

Examination and Counsel of School Children.—The Board of Health of Syracuse, N. Y., in connection with the school officials, has decided that hereafter every pupil in the city schools shall receive a medical examination monthly, as to general health, with particular reference to defects of eyesight; this is also to prevent the spread of infectious diseases. The pupils are to be counseled and advised as to the protection of their health, and the wisest methods for the maintenance of good health and the acquisition of a proper physical development.

Personal.—Dr. Richard W. Bamber, Kendall, has disposed of his property, but will not locate at present.——Dr. James C. Comstock, Binghamton, is dangerously ill, the result of an attack of paralysis.——Dr. Robert H. Phelps, Norwich, has been elected a member of the governing board of physicians, St. Luke's Hospital, vice Dr. L. J. Brooks, deceased.——Dr. Guy C. Bayley, superintendent of Vassar Brothers' Hospital, Poughkeepsie, is dangerously ill from septic infection during an operation.——Dr. William Stump, Utica, has moved to New York City.

New York City.

Increase in Typhoid.—All hospitals report an increase in the number of cases of typhoid fever, and the Board of Health reports 122 cases for the week, as compared with 82 in the corresponding week of 1900.

A Progressive City.—The tax critics point out that New York, with a population of about one-quarter of what it is now, had a Board of Health which cost $40,000 a year against its present expenditure of $1,000,000.

Hospital Blameless.—The coroner's jury, after considering the circumstances surrounding the death of John Chrystie, who died in the Insane Pavilion at Bellevue Hospital, June 18, decided that he died from natural causes, and that the hospital authorities were in no measure responsible for his death. At the autopsy it was discovered that his body was bruised and that two ribs had been broken.

St. Luke's Hospital Cancels Consumptive Contract.—The Board of Directors of St. Luke's Hospital adopted the report of a special committee, September 30, recommending the cancellation of a contract now existing between the Hospital and the House of Rest for Consumptives, which some years ago transferred to the hospital its resources with the understanding that the hospital would thereafter care for consumptive patients.

Bequests to Hospitals.—The late John Gray has bequeathed $5000 to Seney Hospital to endow a bed, to be known as the "Sarah Gray Bed."——By the will of the late Mrs. Harriet B. Ranney, $6000 is left to establish a bed for adults and $3000 for a bed for children at St. Luke's Hospital.——The late Susan Miln, after certain bequests, left the residue of her estate to various charities, including the General Memorial Hospital for the Treatment of Cancer and Allied Diseases and the Home for Incurables.——St. Luke's Hospital will receive a substantial sum from the estate of the late Daniel T. Hoag.

OHIO.

Ohio Board Sustained.—The State Board of Medical Registration and Examination has been placed on a firm foundation by a decision of the Supreme Court of the state, which establishes its right to pass on the competency of Ohio medical institutions.

Typhoid in Toledo.—The health officer, Dr. Walter W. Brand, asserts that there is more typhoid fever in Toledo than the records show. He has therefore mailed to every physician in the city a copy of the rule requiring the report of such cases to the Health Department.

New Doctors Licensed.—At the regular quarterly meeting of the State Board of Medical Registration and Examination, held at Columbus, October 1, sixteen graduates of recognized medical schools of Ohio, who are entitled to exemption from examination under the state board, were granted certificates to practice.

Western Reserve University Medical Department, Cleveland, opened for its annual session, October 2, with about 130 students, the attendance apparently having not been decreased by the increased requirements for admission. The additions to the faculty are Dr. F. C. Waite, Chicago, assistant to the chair of histology and embryology; Dr. Louis W. Ladd, New Haven, Conn., lecturer on clinical microscopy; Dr. H. B. Parker, Baltimore, demonstrator of pathology, and Dr. Roger G. Perkins, Cleveland, lecturer on bacteriology.

Personal.—Dr. Katherine L. Crawford, Toledo, has returned to her home in Ann Arbor.——Dr. John S. Montgomery, Huntsville, was seriously injured in a runaway accident, October 2. ——Dr. Thomas L. Cooksey, Wilmington, has been appointed captain and assistant-surgeon in the National Guard, and assigned to the First Infantry.——Dr. Harry P. Findley has resigned from the staff of the State Hospital, and will practice in Massillon.——Dr. Edward L. Emerich, Wooster, has been appointed on the staff of the State Hospital for the Insane, Massillon.——Dr. George N. Simpson, Warren, has moved to Youngstown.——Captain Jacob R. Welch, assistant-surgeon, O. N. G., Spencerville, has resigned.

Cincinnati.

Dr. Thaddeus A. Reamy entertained the Academy of Medicine at his home in Stockton, October 4.

The annual commencement exercises of the training school for nurses of the Presbyterian Hospital were held October 3. A class of nine was graduated. The annual address was made by Dr. John C. Oliver.

Personal.—Dr. Henry F. Gan, has returned after eighteen months spent in the hospitals of Vienna, Paris and London. ——Dr. Mary E. Cadwallader has been appointed on the staff of the State Hospital for the Insane, Dayton.——Dr. Frank L. Ratterman has sailed for Europe to take up an extended course of study in diseases of the stomach and intestines.——Drs. Burnett Weaver and Dudley Webb have been appointed surgeons to the Cincinnati Traction Company, to succeed Dr. C. S. Muscroft, resigned.

PENNSYLVANIA.

Scarlet fever is prevalent in Homestead.——Typhoid fever is reported to be epidemic in Allegheny.——Diphtheria is so prevalent at McKeesport that the closing of the public schools is being considered.

Personal.—Dr. Michael W. Raub has been reappointed health officer of Lancaster.——Dr. Farnham H. Shaw has located in Wellsboro.——Dr. Arthur C. Wheeler, Erie, has moved to Reynoldsville.——Dr. William L. Grim, West Finley, will move to West Washington, November 1.

Free Hospital for Poor Consumptives.—The colony of consumptives, located under the auspices of this institution at White Haven, now numbers seventeen. The present buildings are a barn and a cottage. Beds are spread on the barn floor and the doors are kept open during the day. Weather paper is being placed on the walls in preparation for the snow, and a hot-water heater will soon be installed to keep out dampness and to modify the temperature about the beds. Nothing, however, is done that will tend to impede the circulation of fresh air. The cottage is used as a dining-hall.

Uniontown Hospital.—A recent news item in The Journal which stated that the Uniontown Hospital Association was building a hospital, and had $5000 subscribed, was partially incorrect, as the State Legislature has appropriated $18,000 for building purposes and $9000 for maintenance for two years. In addition to this, Mr. Josiah V. Thompson has donated two acres of ground, valued at $1000, on which to erect the building, and the citizens of Uniontown and vicinity have already subscribed some $10,000. The trustees are: Hon. Nathaniel Ewing, president; Dr. Thos. N. Eastman, vice-president; Dr. Jacob S. Hackney, secretary; Samuel M. Graham, treasurer, and Hon. Josiah V. Thompson, Hon. A. D. Boyd and O. W. Kennedy.

Philadelphia.

Jefferson Medical College held its opening exercises, October 1. Dr. J. Chalmers Da Costa delivered the opening address.

The Medico-Chirurgical Medical College opened for t session of 1901-1902, October 1. Dr. John C. Heisler delivere an address on the qualities which should be cultivated by t physician.

Contagious Disease.—During September there were 1 cases of smallpox in the city, 234 cases of diphtheria, 15 cases of scarlet fever, 407 cases of typhoid fever and 214 cas of consumption.

Objection to Isolation Hospital.—The plans of the boa of directors of the proposed hospital for contagious disease for which a site was recently purchased at Narberth, have bee abruptly stopped by the authorities of that place.

Registration of Consumptives.—Although six mont have passed since the registration of tuberculosis patients w urged by the medical profession and approved by the Board Health, nothing has been done, because of the Mayor's opp sition.

The new medical laboratory building for the Universit of Pennsylvania will be quadrangular, two stories in heigh above a high basement, and will measure 340 feet front b nearly 200 feet in depth. The first floor of the building wi be devoted to physiology and pharmaco-dynamics, and th second floor will be devoted exclusively to pathology. Th equipment will be adequate.

GENERAL.

Dr. Vincenz Czerny, professor of surgery at the Universit of Heidelberg, is visiting San Francisco, the guest of D Burkan, of that city.

Hospitals in the Philippines.—Surgeon General Georg M. Sternberg, U. S. Army, in a recent interview, expressed th greatest satisfaction over the condition of the hospitals an medical service as he found them in his visit to the islands.

International Quarantine Congress.—Under the patron age of many eminent men abroad, arrangements have been se on foot for assembling an international quarantine congres The movement originates with Assistant Surgeon Frank W Foxworthy, U. S. A., who is at present in Europe. The con gress will attempt to formulate a uniform code of quarantin laws, which shall be the standard for the entire world.

Large Number of Women Studying Medicine i Switzerland.—The women students at Berne outnumber th men by 190 to 174. At Geneva, there are 168 women and 18 men following the medical course. The total number of wome now studying medicine in Switzerland is 511. Mme. Bornstei was recently admitted to the entire privileges of a register physician in Berlin after graduating in Switzerland and Prussia; she was admitted at the same time as her son.

Smallpox Report.—According to the last report of th Marine-Hospital Service, the number of cases of smallpox reported between June 20 and September 20 was 9797, as compared with 3818 during the corresponding period of last year The number of deaths resulting from the cases reported wa but 274, showing a smaller death-rate this year from th scourge. Some states have enjoyed greater freedom from th disease than last year, while a few states make distressingly high reports, notably Pennsylvania, which had 10 cases last year and 1205 this, and New York, which had 7 last year as against 521 this year.

The Death of President McKinley.—The *Progrès Médical* of Paris, speaks with admiration of "the absence of the delays and the distressing indecision, which so often is witnessed at the bedside of persons of prominence. The decision and promptness with which our American confrères complied with the urgent and pressing indication for laparotomy, the clearness and frankness of their bulletins, and also the beautiful fortitude manifested by the unfortunate victim from the moment he was stricken by the assassin to the supreme hour of death." The *Journal de Méd. de Paris* observes: "The only treatment possible was applied in the case of President McKinley, but the bulletins published were most amazingly optimistic. Not only was infection almost certain after such a traumatism, but the symptoms never ceased to be alarming. How was it possible to speak of being out of danger after a laparotomy under such conditions, when the pulse kept at 120 and the temperature between 38 and 39 C.? Either our American confrères were deceived, or for political reasons they wished to reassure public opinion. The report of the autopsy is equally bizarre and inadequate."

CANADA.

Hamilton Medical Society.—This association has passed a resolution urging that an isolation hospital be established in that city. At the next regular meeting of the Society, Dr. Roswell Park, of Buffalo, will contribute a paper on abdominal surgery.

Toronto Senate Elections.—The following members of the Medical Faculty of Toronto University were elected by acclamation at the recent elections for the senate: Mr. Irving H. Cameron, Dr. W. H. B. Aikins, Dr. James M. McCallum and Dr. Adam H. Wright.

Smallpox.—A serious outbreak of smallpox has again broken out at Copper Cliff, near Sudbury, the scene of the extensive epidemic of last spring. The appearance of the disease in that section of Ontario is causing the Provincial Health Department considerable anxiety.

Medical Inspection of Schools.—Some citizens of Toronto are advocating systematic inspection of the public schools by medical practitioners. The Ontario Board of Health has already endorsed this scheme, and the matter will probably now receive more attention.

Victoria Memorial College Hospital, at Revelstroke, had its cornerstone laid on September 29 by the Countess of Minto, who was one of the party conducting the Duke and Duchess of Cornwall on their trip. This hospital is the fourth of its kind organized in western Canada.

Obituary.—Truman W. Duncombe, M.D., Toronto Medical College, 1882, died suddenly at his home in St. Thomas, Ont., October 2, aged 42. He was a prominent and popular practitioner.——Dr. Hugh Bain, Calgary, N. W. T., died, October 2, at his home, aged 49. He was well-known as a prominent practitioner in the Territories.

Effervescent Sodium Phosphate.—The Inland Revenue Department has just published the result of analyses of sixty-four samples of effervescent sodium phosphate. Of this number only thirteen, or 20 per cent., were found to be genuine. The greater number of the adulterated samples have been so characterized as they do not conform to the B. P.

Montreal General Hospital.—Admissions to the wards of the Montreal General Hospital for the month of September numbered 234. The discharges for the same period were 226; the deaths, 14; the daily average of indoor patients, 180. Consultations in the outdoor department numbered 2565. There have been a considerable number of typhoid fever cases.

Appointment of a Special Inspector.—In view of the repeated outbreaks of smallpox in the unorganized townships of northern Ontario, the Provincial Health Department is considering the advisability of appointing a permanent inspector for those districts. The territory extends from the Ottawa River to Rat Portage, twelve hundred miles, and has a population of 100,000.

Toronto Vital Statistics.—In September there were registered in Toronto 339 births, 229 marriages and 253 deaths. During September, 1900, the registrations were: Births, 328; marriages, 187, and deaths, 290. It is said that the registration of births should be much larger as many physicians fail to register these. London's vital statistics for September were as follows: Births, 60; marriages, 66; deaths, 57.

Medical Examinations.—The fall medical examinations were held at Quebec, September 25 and 26. At a meeting of the Board of Governors of the College of Physicians and Surgeons, September 25, the following officers were elected: President, Dr. Lachapelle; vice-presidents, Dr. Wallee, Quebec, and Dr. Craig, Montreal; registrar, Dr. Marsolais, Montreal; treasurer, Dr. Jobin, Quebec, and secretaries, Dr. McDonald, Montreal, and Dr. Paquin, Quebec.

Toronto Clinical Society.—This Society began its 1901-1902 session on the evening of October 3, with the president-elect, Dr. J. F. W. Ross, in the chair. Dr. Bruce presented a hairy tumor, a report of which has already appeared in the columns of The Journal. Dr. A. A. Small showed two interesting cases: One a woman of 40, with a cystic tumor in the left popliteal space, which Dr. Grasett suggested was probably connected with the sheath of a tendon or an enlarged bursa; and a case of polymastia in a woman of 60, who had borne several children. This supposed supernumerary breast was situated just behind the right posterior axillary line and was quite characteristic of a breast, although lactiferous openings could not be defined. It had never enlarged during nursing. The nipple-like tumor had always been present. The opinion was pretty general that the so-called supernumerary breast was a lipoma. Dr. A. A. Macdonald showed a specimen of cystic-adenoma of the breast. He believes in removing the entire breast in such cases.

Toronto Medical Society.—The first regular meeting of this Society was held on the evening of October 3, with the president-elect, Dr. F. N. G. Starr, in the chair. He delivered a very interesting presidential address on eminent members of the profession in Toronto; in days gone by, illustrating this with canvas photographs. Mr. Cameron showed some very interesting calculi extracted from an old man of 76, by high section, some fourteen of these being found in the cul-de-sac, behind the prostate. Dr. Graham Chambers showed a girl of 13 years who had hydro-vacciniforme for ten years. Dr. Primrose and Dr. Chambers showed a young man of 25 with blastomycosis. The two lantern-slide photos shown, exhibited warty tumors on the right malar bone, one on the neck, one on the shoulder and another at the inner canthus of the right eye, which resembled very much an epithelioma. The fungus was readily found under the microscope. Excision and the actual cautery in the hands of Dr. Primrose is effecting a cure.

Opening of the Medical Schools.—The medical department of the Western University at London opened for the winter session, October 1.——Toronto School of Medicine resumed its work on the same date. Professor J. F. W. Ross delivered the opening lecture, taking for his subject, "The Indian Medicine Man." Before a single lecture had been delivered a larger number of freshmen had been enrolled than for any previous year. A demand will probably be made for additional accommodation from the provincial government.——Queen's, at Kingston, opened October 2. New additions have been completed during the summer, at a cost of $10,000. The Reverend Principal Grant, who is confined with a serious illness, sent a message to the assembled students, exhorting them to take up their studies seriously from the outset. He said that hereafter there would be greater pains taken to prevent the graduation of irreverent and half-taught young doctors from Queen's.——Bishop's Medical College also opened during the week, the dean, Dr. F. W. Campbell, delivering the opening lecture. It is only a few years since the standard for medical matriculation was raised in Ontario, but with the increasing influx into medicine, it would appear as though the B.A. standard of matriculation was in the near future.

FOREIGN.

Professor Virchow has had the largest municipal hospital in Berlin named after him, in honor of his coming eightieth birthday. The city has also voted 100,000 marks to the Virchow House, a charitable institution.

Bubonic Plague Threatens.—A rat caught on board an East India liner was found to contain pest bacilli. It is feared that the plague may thus have been carried into France by the escape of other infected rats at various ports.

Smallpox in London.—There were 128 cases of smallpox in the London hospitals, September 30; there are in all 4885 patients in the hospitals. The medical officers are busy revaccinating, and scarlet fever and diphtheria are also causing the Health Department considerable concern.

Honors to the Memory of Chassaignac and Maisonneuve.—During the French Congress of Gynecology which was held at Nantes, the latter part of September, portrait busts of these two famous sons of Nantes were unveiled with appropriate ceremonies, followed by a banquet of the Chassaignac committee and the members of the congress. The busts are in the grounds of the public hospital.

Deaths Abroad.—Our Brazilian exchanges announce the death of A. R. de Alvarenga, President of the Faculty of Medicine at Rio de Janeiro, from 1889 until last February. The titles of Baron and Viscount had been conferred upon him in token of appreciation of his services to the late Emperor, Pedro II, and the Republic has also conferred signal honors upon him. The medical school was closed for the week following his death as a mark of respect to his memory. He was aged 69.——The death of Dr. Cuneo, chief of the Medical Corps of the Navy of

France, occurred at Vichy, September 4.——Dr. Vaucher, professor of obstetrics and gynecology, at Geneva, is dead.

Prevention of Tuberculosis.—The Minister of Public Works of France has sent a circular letter to all railway companies, pointing out the best manner in which to combat the propagation of tuberculosis among their employes. The companies are already very careful, accepting only applicants shown by medical examination to be free from the malady. The future aim will be to give outdoor positions to those who have contracted it since entering the service.——The Prussian School Inspectors are paying particular attention to the prevention of the disease. The Minister of Public Instruction has recently sent to the Department of School Inspection copies of a pamphlet written by an American physician on this subject, with an order to the inspectors to consult with the teachers regarding preventive measures.

PARIS LETTER.

Cigarette Smoking Compared to Cigars.

The Royal Medical Academy of Belgium has published a report by Dr. Kuborn on the use of tobacco, in which the author lays down some principles as to the conditions needed to avoid the noxious effects observed at a certain age. One should avoid damp tobacco, which allows nicotin to escape with the steam without being decomposed. Use tobacco which contains a small amount of nicotin, and do not smoke before meals. Smoke with the help of a cigar or cigarette holder, throw away the last quarter of a cigar and smoke in a well-ventilated room. Cigarettes are the least dangerous form of tobacco.

The Microbe of Dysentery.

Dr. Lesage, physician of the Paris hospitals, who is a well-known bacteriologist, especially in intestinal affections, has just published in the *Presse Medicale* of August 17 a short notice on a microbe of dysentery. An extract of this will be of use as a means of comparing it with what has been recently discovered in the Philippine Islands, and with Shiga's bacillus. Dr. Lemoine was able to examine a large number of cases of dysentery in the service of Dr. Galliot, at Toulon, and he was able to note the following facts: 1. In cases of dysentery from China, Cochinchina, Algeria or Toulon, there is to be found a micro-organism the number of which increases with the progress of the disease and diminishes when convalescence sets in. 2. This parasite is [illegible] a micrococcus or streptococcus, generally [illegible] with equal or unequal grains. In the latter case the micro-organism has the appearance of a balloon with its basket. 3. This microbe is discolored by Gram's method, does not coagulate milk and does not grow on potatoes. 4. It is to be found in the various intestinal products of dysentery, and after death in the veins of the mesentery and the glands of the same order. 5. Injected into the rabbit and guinea-pig, it produces septicemia without intestinal localization. With the cat, however, there is localization on the large intestine, with lesions identical to those observed in man.

New Treatment of Blennorrhagia.

A new treatment for blennorrhagia has been recommended by Dr. de Brun, professor at the Medical Faculty of Bayreuth. It consists in the use of picric acid. A 1 per cent. solution can be used, but is found to be rather painful, so a solution of 0.5 per cent. is usually employed. Only 5 to 6 cubic centimeters should be injected for a few minutes, and this should be repeated two or three times a day. A cure is obtained after four or five days. In chronic forms Dr. de Brun has obtained good results when the disease only existed in the anterior part of the canal. The result of the injection is shown by the change in the coloration of the flow. A bacteriologic examination shows a rapid diminution of the gonococci.

Treatment of Rectal Stenosis.

Dr. Chaput has obtained in quite a number of cases of medullar cocainization anesthesia of the arm and even of the face. Out of 102 observations there were 31 cases of anesthesia of the arm, 4 of the face and 9 of the head in its entirety. At one of the last meetings of the Society of Surgery, the treatment of rectal stenosis was discussed; two observations furnished by Dr. Souligoux and Dr. Walther showed the advantages derived from performing enterotomy in the iliac region, and in the first of the two cases, dilating from above. Later this opening was closed and the patient is supposed to dilate the rectum with catheters used twice a week.

Electricity in Blennorrhagic Arthritis.

Dr. Mathieu, at a recent meeting of the Society of Therapeutics, described the results obtained by the use of electricity in six cas[illegible] rheumatism. These observations had been [illegible] ·elorme, who noted some improvement the day after the first use of the galvanic current. There was diminution of the edema and of the pain. A comparison was established by using on one articulation the galvanic current and on another salicylate of methyl. It was found that articulations treated by salicylate were not affected by the treatment, while those subjected to the electrical treatment were much improved.

Tuffier's Statistics on Appendicitis.

Dr. Tuffier's statistics in the treatment of appendicitis have been recently published in a thesis presented at the Paris Faculty of Medicine. There were 52 cases operated upon during the last eighteen months with the following results:

Six operations for general peritonitis, with 4 deaths; 22 observations of pericecal abscess, 19 immediate operations, with 19 cures; one deferred with subsequent death; another with consequent fistula, and still another was not operated on and died; 8 observations of acute appendicitis, with 7 operations followed by success; in one case the operation was deferred and the patient died before being operated upon; 16 patients were operated on sometime after their attack and all recovered.

According to Dr. Dubarry, who is the author of this thesis, the opinion of Professor Dieulafoy that the only treatment of appendicitis is to be found in surgery, is correct, and peritonitis, abscesses or acute attacks of appendicitis should be operated upon.

Correspondence.

A McKinley Memorial.

New York, October 7, 1901.

To the Editor:—During the past week some lay and some medical journals announced that it was intended to erect in Washington a McKinley Hospital in honor of our late beloved President.

Beautiful as this idea may be, I believe that a little memorial hospital, located in Washington, is not a great enough tribute to a nation's president such as was William McKinley. Furthermore, while I would not wish to say that there is no room for a hospital for the treatment of general diseases in Washington, I know that there is no urgent need for it. On the other hand, I know, and all physicians and charity workers of our large eastern and western cities will bear me out when I say that there is a crying and urgent need of a sanatorium, or rather several sanatoria where the many little scrofulous and tuberculous children of poor parents could receive treatment, care and the necessary education. France, Germany, Holland, Italy, and the Scandinavian countries, all have numerous seaside sanatoria where the little sufferers afflicted with the above-mentioned diseases receive care. The seacoast climates, combined with proper sanatorium treatment, seem to produce really wonderful results in scrofulous and tuberculous children. The reports of some of the European seaside sanatoria state an average of 75 per cent. of cures.

We in America have, with the exception of one or two small children's hospitals and a few floating hospitals during the summer months, no such institutions. In an address delivered at the recent Congress on Tuberculosis in London, I said that in our eagerness to take care of the consumptive adult we should not forget the little sufferers afflicted with the same or other tuberculous diseases. To treat the scrofulous or tuberculous child—scrofulosis being only a milder form of tuberculosis—or to prevent a child with a hereditary tendency from developing consumption or any other form of tuberculous disease, means the saving of a life and the preservation of a perhaps very useful future citizen.

To realize the urgent need of seaside sanatoria for children one must have visited the crowded tenement districts of our great cities and seen the large number of scrofulous and tuberculous children there, and the many who bear on their pale little faces the stamp of candidates for consumption—pulmonary tuberculosis.

There are already laws in some states prohibiting the tuberculous child from attending public school; but so far as I know none of these states have provided other places where children suffering from a chronic communicable, but also curable disease, can receive the education to which they are entitled, much less where they could have a chance of being cured from their affliction. The results obtained in some of our American sanatoria for the treatment of tuberculous adults are as good as any of those obtained in European institutions. The preventive measures inaugurated by our New York Board of Health have not only served as models for other American cities, but have been imitated by many European municipalities and found to be the most practical and efficacious. We have already a number of sanatoria for the treatment of the consumptive poor adults, though by no means enough of them. However, in nearly every state of the Union the question of providing institutions for adult tuberculous patients with little or no means is now being agitated. Only for the countless little ones suffering from the same or other tuberculous diseases there is nothing done.

Our martyred President had two children, and these he lost. He dearly loved little children, and the creation of a sanatorium for the treatment and prevention of a disease with which so many American children are afflicted, would surely be a fitting memorial to this great man and lover of children. "McKinley Sanatorium for the Treatment and Prevention of Tuberculous Diseases in Children" should be the name of such an institution.

The meaning of the name William McKinley, written on the portals of these houses of hope for many a suffering mother's heart, will be made clear to these little inmates by their teachers and grown-up friends. The word McKinley will embody to these little sufferers all that is needed to make them good patients, obedient scholars, noble men and women, true American citizens. McKinley's fortitude during the last days of his life must teach them what all patients need: Trust in God, confidence in their physician, patience. His words of forgiveness to the very man who slew him must show these little children the sublimity and nobleness of his character. McKinley's life as a man, citizen, patriot, and president embodied all that is truly American. A better example to teach our children the meaning of true manhood and true patriotism we can not find.

Let all American men and women who can afford it contribute through their children, or through their children friends, toward the realization of this McKinley Sanatorium.

In letting the children of parents of means who are happy and well, bring their mites toward a movement of this kind a lesson of charity and patriotism may be taught to them as well. There will be found in every community responsible and patriotic citizens to take this matter in hand and bring it to a successful issue. Let each state contribute enough to have its own pavilion to which to send its children. Let the Atlantic and Pacific coast be lined with such institutions, one or two pavilions for each state, according to its needs. Let good schools be attached to each sanatorium so that the intellectual development of the children may not suffer.

There exists in the North Sea, or German Ocean, on the island called Norderney, a beautiful flourishing sanatorium for the treatment of tuberculous children. Its name is "Kaiser Friederich Hospiz," and it was erected in memory of that unfortunate emperor, Frederick the Third, whom the German people so fondly call "Frederick the Noble." In the fortitude of this beloved sovereign, in his patience, in his martyrdom, in his love for the people, in his ideas and ideals of what should constitute a free and just nation, there is a great similarity to our beloved McKinley.

We, too, may call our martyred ruler "the Noble," and to his memory erect a memorial of practical utility. Let us build an institution where the lives of American children can be saved, to be sent forth in health and vigor to their respective communities, and to help finish the work for which McKinley lived and died; to make the American nation the greatest, the noblest, the foremost of the world. S. A. Knopf, M.D.

Married.

Arthur Allen Libby, M.D., Boston, Mass., to Miss Florence Hunt, Reading, Mass., October 3.

Martin L. Hindley, M.D., Monroeville, Ohio, to Miss Myrtie Morrow, Martel, Ohio, October 2.

Christian Storz, M.D., to Miss Pauline C. Lotterer, both of Toledo, Ohio, at Delphos, Ohio, September 25.

Dr. Albert S. Horton, M.D., to Miss Josephine Lulu Dwyer, both of Baltimore, at Hampton, Va., September 25.

Cornelius F. McCarthy, M.D., Batavia, N. Y., to Miss Georgiana A. Merrill, Byron, N. Y., at Watkins, N. Y., September 25.

Frederick Allport Dale, M.D., assistant surgeon U. S. Army, Aparri, Philippine Islands, to Miss Caroline Maude Kern, Philadelphia, Pa., September 4.

Deaths and Obituaries

Samuel J. Jones, M.D., University of Pennsylvania, 1860, a member of the American Medical Association, died from pneumonia, after an illness of less than a week, October 4, aged 65. He was born in Bainbridge, Pa., in 1836, the son of a physician. He received his education at Dickinson College. He served throughout the Civil war as a medical officer in the U. S. Navy. In 1868, he resigned from the navy and settled in Chicago, making a specialty of diseases of the eye and ear. From 1870 to 1897 he was professor of ophthalmology and otology at the Chicago Medical College, and for many years was surgeon to the eye and ear department of St. Luke's Hospital, Mercy Hospital and the South Side Dispensary. For the last two years, since his retirement from active practice, he had been conducting an active propaganda against street noises, to which he had always been particularly sensitive. He was for several years editor of the *Chicago Medical Journal and Examiner*.

Aaron Cornish, M.D., Castleton (Vt.) Medical College, 1855, died at his residence in New Bedford, Mass., after a lingering illness, September 26, aged 68. He was a native of Plymouth, studied medicine first at Albany, completing his course at Castleton. He first practiced in Boonville, N. Y., and, at the outbreak of the Civil war, he became surgeon of the Ninety-Seventh New York Infantry, and served until 1863, when he succeeded to the practice of his uncle, Dr. Aaron Cornish, Sr., New Bedford.

Daniel E. Thayer, M.D., Chicago Medical College, 1871, died at a sanatorium in Winchendon, Mass., September 29, aged 58. His death was due to nervous trouble, the result of injuries received in a runaway accident several months ago. After his graduation he practiced in Virginia for seven years, then at Cheshire, Mass., for ten years and afterward made his home at Adams. He had served in the Legislature and was prominent in the local and state medical societies.

Richard H. Whitfield, M.D., University of Pennsylvania, 1853, a prominent citizen and physician of Meridian, Miss., died at his home in that city after an illness of four months, September 30, aged 71. He represented Lauderdale County in the Legislature and served as surgeon in the Confederate army during the siege of Vicksburg, where he had charge of one of the hospitals.

George Shivel, M.D., Jefferson Medical College, 1851, a retired practitioner of Philadelphia, died in the Municipal Hospital in that city from smallpox, September 29, after an illness of one week. During the Civil war he became well known from his connection with the military hospitals.

Rev. James Bryan Purcell, M.D., University of Maryland, Baltimore, 1866, of St. Barnabas P. E. Church, Sykesville, Carroll County, Md., died there September 24, aged 59. He was a native of Dublin, Ireland, and served for a time as Acting Assistant-Surgeon, U. S. Army.

Robert M. C. Hill, M.D., New York University, 1860, a practitioner of Mount Meigs, Ala., and who was a native of

Montgomery County, died at his home, September 20, aged 63. He was a surgeon in the Confederate service during the Civil war.

Francis E. Hines, M.D., Harvard University, Boston, 1879, a resident of Salem since that time, for 12 years a member of the School Board and at one time a member of the Legislature, died at his home in Salem, September 30.

Preston Fisher, M.D., Jefferson Medical College, Philadelphia, 1851, died at Boston, September 23, aged 72. He practiced for many years at Orono, Foxcroft, Maine, but of late years had resided in Jamaica Plain, Mass.

James W. Graves, M.D., Trinity Medical College, Toronto, 1866, one of the best-known practitioners in the thumb of Michigan, died at his home in Caro, from hemorrhage from the stomach, September 28, aged 68.

Nathaniel P. Wright, M.D., University of Louisville, 1876, a prominent physician of Lowry City, Mo., died at his home in that place from gastric ulcer, after an illness of several months, September 30, aged 53.

Abram Litton, a pioneer chemist and scientist of St. Louis, for half a century professor of chemistry in Washington University, and St. Louis Medical College, died at his home in St. Louis, September 22, aged 87.

Frank C. Cullen, M.D., Rush Medical College, 1887, died at his residence in Chicago, September 29, from typhoid fever, after an illness of two weeks. He was at one time registrar of Cook County Hospital.

Job S. Wallace, M.D., Northwestern Medical College, St. Joseph, Mo., 1889, a member of the American Medical Association, died from the effects of morphin, taken with suicidal intent, September 28.

Andrew J. Rogan, M.D., Albany Medical College, who practiced in South Shaftsbury and North Bennington, Vt., died in Colorado, where he had gone for his health eighteen months ago.

Elisha O. Mannakee, M.D., University of Louisville, Ky., 1866, for nearly thirty years a resident and practitioner of Washington, D. C., died at his home in that city, September 23.

John S. McNutt, M.D., Cincinnati College of Medicine and Surgery, 1867, for thirty years a practitioner of Philadelphia, died at his home in that city, September 28.

James Walter Dunphy, M.D., College of Physicians and Surgeons, New York, 1895, died at the home of his parents in New York City, October 1, aged 26.

Albert V. Benedict, M.D., Rush Medical College, Chicago, 1881, a practitioner of Portal, N. Dak., died from diabetes, at Braidentown, Fla., September 15.

McPherson Barnitz, M.D., Tulane University, New Orleans, La., 1899, died from heart disease at his home in San Antonia, Texas, September 23.

Percy J. Shute, M.D., College of Physicians and Surgeons, New York, 1896, died from nephritis, at his home in Jeffersonville, N. Y., September 29.

Albert L. Wagner, M.D., College of Physicians and Surgeons, Chicago, 1885, died at his home in La Paz, Ind., September 28, aged 41.

Direct Medicinal Injections in Lungs.—The *Union Med. du Nord-Est* of July 30, contains a communication from G. Rosenthal, describing the great benefit to be derived from direct injection of medicinal substances into the trachea, just below the cricoid cartilage, the patient's head being bent slightly forward. There is no coughing nor any kind of spasm, and the fluid can be injected as slowly as is desired. He uses a needle, as for hypodermic injection, connected by a rubber tube, with the receptacle holding the medicated solution. Absorption through the lungs proceeds as rapidly as through the veins, he asserts, and the lung tissue can thus be directly influenced. He sometimes leaves the needle in place for a week at a time, renewing the injection each day, and afterward inserting a stopper and fastening it in place with collodion.

Testimonial Banquet in Honor of
Dr. Nathan Smith Davis.

A testimonial banquet was given to Dr. N. S. Davis, the Father of the American Medical Association, Nestor of the medical profession, first editor of this journal, and founder of the Mercy Hospital, at the Auditorium Hotel, Oct. 5, 1901, under the auspices of the Chicago Medical Society.

The event was a grand success. Approximately three hundred and fifty physicians from Chicago and various parts of the country attended the feast. The gathering was a representative one and typified in a striking manner the high esteem in which Dr. Davis is held by the profession. Cities outside of Chicago were well represented. The tables were tastefully decorated with flowers. The speeches were timely, replete with good thoughts, characterized by zest, and interspersed with wit and humor. The reminiscences about Dr. Davis were fraught with interest, and their recital by Drs. Andrews, Waxham, Hollister and Bridge created amusement.

Dr. Davis sat between Drs. Fenger and Billings, the one, the highest embodiment of modern surgical pathology, the other, representing all that is progressive and modern in internal medicine. After the banquet Dr. Christian Fenger, president of the Chicago Medical Society, rapped for order, and introduced Dr. James H. Stowell, who said that the members of the profession had assembled to pay their respects to one of the greatest examples of professional honor and dignity in the medical profession. He said it was unnecessary to call attention to the many eminent pupils that had been sent out under the instruction of the distinguished guest. The Deans of three of the largest medical colleges in Chicago were pupils of Dr. Davis. Throughout the country graduates from the Chicago Medical College were occupying positions of eminence, and among them were Drs. Nicholas Senn, Norman Bridge, Frank Billings, Nathan Smith Davis, Jr., Arthur R. Edwards, Roswell Park, John A. Fordyce, and many others, who had in some way or other been honored by their professional brethren.

The toastmaster of the evening, Dr. Frank Billings, said that to preside at a banquet given in honor of Dr. Davis was an honor second only to that which Dr. Davis was receiving. Dr. Davis did not belong to Chicago alone, but to the whole country. Dr. Davis was a New Yorker by birth, was born Jan. 19, 1817, and graduated in medicine in 1837, when he was not quite 21 years of age, from the College of Physicians and Surgeons of the Western District of New York. He then practiced medicine in Binghamton, N. Y., for about ten years, and, seeking wider fields, or people in a better field seeking him, he went to New York City, where he remained about two years. Then Chicago, always looking for something better, found Dr. Davis there, and invited him to Chicago. He came here in 1849 and taught in Rush Medical College for the next ten years. Not satisfied with the method of teaching at that time, and desiring a different method and a longer course, he, with others, severed his connection with that school and founded the Chicago Medical College in 1859. He said that the history of Dr. Davis was known to all, and it was hardly necessary for him to take time in repeating it. He only desired to say that Dr. Davis had become known throughout the whole country as a medical teacher, as a lever to elevate medical education. Practically, it was due to Dr. Davis that the first steps toward a better method of medical education were taken in America, and it was he and his colleagues who instituted the graded method of instruction in medical schools. The speaker said that Dr. Davis and his colleagues had not received the credit that was due them for this, and that Eastern medical schools had taken the credit, although they had adopted the graded method of instruction afterwards. As a teacher he was eminent. Those who had sat at his feet and had listened to his lectures would remember as long as they lived his graphic description of disease, even in a didactic lecture. When it came to the demonstration of a case, he did not think there was any clinician abroad or in this country who could excel Dr. Davis in the matter of clinical teaching. The work of Dr. Davis was not alone confined to medical teaching, for it was through his efforts that the American Medical Association was founded, and he is called the Father of the American Medical Association. Dr. Davis was the founder of Mercy Hospital. Dr. Davis had been president of the Illinois State Medical Society, of the Chicago Medical Society, of the American Medical Association, and the only American who was ever president of an international medical congress. Dr. Billings then dwelt at length upon some of the chief characteristics of Dr. Davis' life, among which were: "Industry, tenacity of purpose, integrity; progressiveness; liberality, a Christian gentleman."

Dr. Edward F. Wells presented the loving cup to Dr. Davis. He said:

"Honored Sir and Guests: In behalf of the medical profession of Chicago and of the whole country, it is my privilege to present to you this loving cup as a token of the esteem in which you are held by your associates, and as an expression of their appreciation of your valuable labors in the advancement of scientific, practical, academic and social medicine.

"This beautiful cup, of Grecian design, is, in its lines and proportions, a model of simple, vigorous dignity, and was selected as being peculiarly emblematic of your character and career. Engraved upon one side is an excellent likeness of yourself; upon another is the leaf of victory, and beneath it the inscription, *Palmam qui meruit ferat*—let him who has won it bear the palm—and beneath this, 'Pioneer in local and national medical organization, and in graded medical instruction'; and upon the other is this memorial tribute: 'Presented to Nathan Smith Davis, A.M., M.D., LL.D., in recognition of his long and distinguished services to medicine, in its every field of usefulness, by the members of that profession which he has so conspicuously adorned, and to whose shield he has given an added luster.'

"Few possess the creative genius necessary to initiate great forward movements in public affairs, and fewer yet are permitted to see the realization of their lofty conceptions. But you, sir, are singularly fortunate in both these respects; and, now, after these many years, you may stand before the bow of promise, supported, as it is, upon one side by the fathers of medicine, resting upon the adamantine foundations of experience and truth, and upon the other by the moderns, standing upon the broad expanse of experiment and fact, and, looking through, view with satisfaction the fair and boundless plains of the future as they stretch out beyond."

When Dr. Davis arose to make a speech accepting the loving cup, he was greeted with loud and prolonged applause, and three hurrahs were lustily given for the venerable guest. Dr. Davis was visibly affected by the ovation, but spoke in a deliberate manner, as follows: "Mr. Toastmaster, and Fellow Members of the Medical Profession: It is useless for me to say that there are no words at my command by which I can convey my idea of the gratitude that fills my soul at the present time. If there is any particular thing that has guided my course through life, and if I have been able to contribute anything of value that justifies your presence and this most generous exhibition of your kindness and respect to me, it is from a very simple principle of action. At the age of seven years, as a boy who had never been outside of his father's farm, born in a log house, and when still in a log house, I was called to the bedside of my dying mother to receive her last words. I was the youngest of a family of seven children; I was in my seventh year. It made a vivid impression upon my mind. She was a Christian—a reader of the Bible. She said to me that she wished me to be a good boy, to learn to worship God, and to do good to my fellow-men. I promised her I would. Of course, I did not realize the importance or bearing of that promise at that early period of life; but an impression was made upon my mind, and from that day to this the rule of my life has been, that whatever comes up that seems to be important and will improve my fellow-men, my impulse is to do what I can to help it along. (Applause.) That is the whole foundation of it. I refused to undertake anything the results of which would not be beneficial to those around me, whatever it might be. The question was, Would it benefit my fellow-men? If it would, I supported it. I refused, on the other hand, to lay up enmity against any human being, and to-day I stand here and say that I know of no man or woman for whom I have an evil wish, and there is not one to whom I would not extend a helping hand at any moment if they were within my reach and needed it. (Applause.)

"On this principle of action and reading the book that my mother pointed to and taught me to read, there was revealed a habit that in old times the patriarchs often formed a covenant with their God, and in my innocent early boyhood, as I grew on, a proposition was made for me to study medicine. I no sooner began than I formed a covenant with my Creator, that he would guide me, so that I could be qualified to do good to the sick, to alleviate human suffering, and to prolong human life. I dedicated my life to that great leading idea, and from that day to this I have striven to follow in that line.

"It was not long before I stumbled on the fact that the system of medical education was a very ridiculous one, for I went each year to the college and went over the same thing—six lectures a week, and skimmed the whole field in sixteen weeks. I thought that was very queer. I listened to these lectures every day, but studied only three of them. I left the other three for next year to make up. I made my own division. As soon as I graduated and got into practice, in about three years I was a delegate to the New York State Medical Society. The first thing I did was to introduce a series of resolutions that the term of medical education ought to be extended to not less than six months, at least, and the course of instruction should be graded. I was criticised for this, and the resolutions were promptly laid on the table. The gentleman who made the motion to lay the resolutions on the table happened to be a professor in the medical school from which I graduated. There was one man there who seconded the resolutions that were laid on the table. I hunted him out, and had an earnest conversation with him regarding the resolutions, and I said something to the effect that if this was the way they were going to serve any measures that I might bring before the convention, I should not travel by old-fashioned stage coaches from Binghamton to Albany many times to attend an association on such a basis. The professor, who introduced the resolutions, had heard the substance of our conversation, and after he had taken his dinner and the association reconvened, he moved to take the resolutions from off the table. This permitted one hour's discussion, and by means of this discussion we gained time enough to have them referred to a committee and to postpone the resolutions for renewed discussion until the following year. The next year we discussed them again, and the fight was continued until it amounted to this, that we were having a standard of education in New York as high as it was in any other medical college in the United States, and that if we undertook to make a six months' term, graded courses, the only effect would be to send students to Boston on the one hand, and to Philadelphia on the other, and we would benefit nobody. But how were we to get out of this? If one state can not move a peg without the rest, let us have the rest, and a resolution was adopted to have a national meeting of all the institutions for that purpose. The resolution was seconded, and after a minute or two of silence, and a little laughter, it was easy for them to see that Davis did not want to fool away his time, and they said let him work. And so they passed the resolution for a national convention and appointed me chairman of the committee to carry it out. I did carry it out, and the result you know. I do not need to tell you about it; you know it; that is the secret of the story. It was not my planning; it was simply done on the principle of doing right and sticking to the right whenever an opportunity occurs. It is just so in regard to introducing any other thing that I have helped. It is simply the opportunity. I go into it, and I know no other way to accomplish it. I have no contrivance about it. It is simply to do what comes before me, and do it with all my heart. I don't want to make any half-way work of it. Dr. Billings has said that when I took hold of a thing I never let loose. Why should I? My old friend, A. B. Palmer, said once that I had been harping at the same thing for twenty years. My only answer to him was, If it is right and will benefit mankind, harp on it not only twenty, but forty years, until it is done.

"My friends, I don't want to tire you by reciting details. Please accept my most cordial thanks for this demonstration. It will probably be the last time I shall have an opportunity to address you. But if you want to promote harmony, cordiality, advancement; if you want to build up, stop pulling down anybody. Never pull down, but build up, and if your neighbor does not do as you think he ought to do, talk about his good qualities, and let his bad ones go. You will soon establish harmony; you will soon have cordiality; you will have your own heart free, and your conscience will be right before your God. You will have neither enemies here nor hereafter. I know no enemies to-night; I have no enmities; I am satisfied with life.

"I am sometimes lonesome because I so rarely meet one of my early comrades—lonesome because they are gone. But I am going to join them before long. I do not expect to tarry a great while. But I have no care about that. I live so that I am ready each day to go. I have no settlements to make: I have no great fortune to give away; I have got enough for my comforts, enough to clothe and feed me as long as I live. That is all I want. I would not die worth a hundred millions of dollars; I should be afraid I had not done my duty."

Dr. Charles A. L. Reed, of Cincinnati, was then introduced, and responded to the toast, "The American Physician."

Born to carve his name
Upon the highest pinnacle of fame.

Dr. Reed said in part: "It is appropriate that the American physician should be toasted at this festal board, around which are gathered from all parts of the great republic, American physicians who have come to honor one of their most distinguished and venerable living colleagues. To me has been assigned the pleasant task of responding to this toast. That duty would be easily discharged if I were simply to speak of the ideal characteristics of the American physician; for if I were to thus confine my remarks and speak only of birth, of education, of scientific attainments, of the lofty ideals of character, of the exemplification of Christian virtue, it would be necessary for me only to stand mutely in your presence and point to the distinguished guest of the evening. It may, however, be appropriate for us to consider the American physician from a concrete standpoint. If we were to consider him from his starting point, we must recognize the American physician at the time when the American physician was not an American physician. When, in other words, he was a distinct European product, practicing medicine upon the Western Continent. This was true in our Colonial period, but with the birth of nationality, there was also the birth of the American physician and the establishment of the medical school in the United States was an associated incident of the creation of the American physician. But the primitive medical school of America, like the original physician that stood as the type of the faculty of that institution, was largely of exotic origin. We devoted ourselves at that time to the teaching of science as it had been discovered, taught and amplified in foreign countries. English influence was dominant; French influence was pronounced; German influence had no footing at that time in America. But with the succeeding generations, the American physician became an established fact, a product of our schools, and we found him exemplifying, even in that early day, those attributes which have characterized the practitioner of medicine on this Continent—independence of thought, independence

NATHAN SMITH DAVIS, A.M., M.D., LL.D.

of action, yet always in conformity with the overriding, overpowering influence of law, not statutory law, of which there was none, but of those eternal laws that make for good, that make for truth, that make for happiness. But in the carrying out of these fundamental principles the American physician early dethroned personal authority and became an actor upon a scale of independence that has but rarely characterized the profession in other countries. . . . American medicine has added to the great sum of our knowledge. Science has been evolved by those practitioners in the remoter districts and towns. McDowell, in his little village in Kentucky; Sims, in the little town in Alabama; Batty, in the little village in Georgia; Wells, with his anesthesia in the little town of New Haven—all of them far removed from the influence of the schools—brought to the light of humanity those great truths which have done so much to relieve suffering humanity and to prolong human life." After referring to the struggle of physicians in the early days, Dr. Reed concluded as follows: "But little needs to be said for the American physician; from seaboard to seaboard, from lake to gulf, in every hamlet, he ministers to stricken humanity, and let me venture the belief that the American physician in the aggregate, wherever found, is actuated largely by those same motives, by those same deeply-rooted sentiments that Dr. Davis imbibed at the bedside of his dying mother. Let us, therefore, with all honor speak, not egotistically of ourselves, but of that great, typical character that we are constantly endeavoring to emulate, the American physician, than whom there stands before the American public, there stands before the world, no more distinguished or worthy exemplar than Nathan Smith Davis."

(Loud and prolonged applause.)

Dr. Donald Maclean, of Detroit, Mich., responded to the toast, "International Medicine."

For the whole world is a stage—
Let us hear of the acting.

He said he felt it was a great privilege to be present and take part in the exercises of the evening, and to pay his respects to his old and venerable and highly-respected friend, Dr. Davis. (Applause.) The subject of international medicine was one that reminded him of the lines written by one of the profession, Dr. Oliver Wendell Holmes, who said:

"As Life's unending column pours,
Two marshaled hosts are seen—
Two armies on the trampled shores
That Death flows back between.

One marches to the drum-beat's roll,
The wide-mouthed clarion's bray,
And bears upon a crimson scroll,
'Our glory is to slay.'

One moves in silence by the stream,
With sad, yet watchful, eyes,
Calm as the patient planet's gleam
That walks the clouded skies.

Along its front no sabres shine,
No blood-red pennons wave;
Its banner bears the single line,
'Our duty is to save.'"

He thought the above verses represented truly and fairly international medicine. The profession could never repay Dr. Davis, nor individually express their gratitude for what he had done, and we could say with the poet, Burns:

"The bridegroom may forget the bride whom he's to wed;
The monarch may forget his crown;
The mother may forget the child that smiles so sweetly on her knee;
But I remember thee, Glencairn, and all that thou hast done for me."

Reminiscences of Dr. Davis were related by Drs. John H. Hollister, Frank X. Waxham, Norman Bridge, and Edmund Andrews.

The toast, "Western Medicine," was responded to by Dr. Archibald Church, who, among other things, said: "We do not, for a moment, think of Trousseau as hampered by the walls of Paris; nor Sydenham confined by the geography of London; nor Graves hampered by the purlieus of Dublin; nor Flint cooped up in the Island of Manhattan; nor is Davis limited to the confines of the city of Chicago. It is our privilege to-night: it is the privilege of the profession of America—nay, more, it is the privilege of the profession of the entire world—to read in the galaxy of clinical masters the name of Nathan Smith Davis."

(Loud applause.)

Dr. Victor C. Vaughan, of Ann Arbor, Mich., responded to the toast, "Medical Education."

"Knowledge comes, but wisdom lingers."
How, then, can best be told
"The fairy tales of science, and the long
Result of time?"

Medical education in this country, even at its best, is in somewhat a chaotic state. He had heard a great deal about the elective system in medical education, by which the student was allowed to select courses and take them in whatever manner he chose. Most of the leading literary colleges in this country had adopted the elective system; some of the medical colleges had also adopted it. He thought it was in consonance with American ways, namely, that every young man should have his choice, and that the man beginning the study of medicine had more wisdom than the man who taught it. After referring to the advantages and disadvantages of the elective system of medical education, the peroration of Dr. Vaughan was as follows: "Honored and most worthy guest: We come together to-night from near and from afar to give to you some outward token of our honor and esteem, and we have for you, who to-night has been fittingly called the Nestor of American Medicine, the greatest of respect. For more than threescore years you have labored diligently, worthily and successfully in our profession. Your life has been to us both an example and inspiration. To many here to-night and to thousands of others scattered over this broad country you have been a beloved teacher and an admired master. To all of us you have been and are still a respected older brother, and an honored friend. Your words have always fallen upon grateful ears; your deeds have ever been witnessed by approving eyes, and your friendship is cherished in many a loving heart. In our busy administrations to the sick; in our ceaseless search for truth in the laboratory, we seldom have the opportunity of expressing our appreciation for one another. But so great and so helpful has been the service that you have rendered to us, your younger brothers, that to-night we have come, laying aside our daily tasks, to offer to you a tribute of our love and admiration. Life is a mystery which it has not been given to man to solve. We know not whence we came, nor can we name the land to which we journey. But we do know, that he who lends a helping hand to his fellow-men, as we travel along life's dusty and stony pathway, is a benefactor of his race.

"There is a Hindu legend which accounts for the origin of our profession in something like the following manner: An intelligent Indian Prince in the time long ago sought one of the most renowned temples of Buddha, and prostrating himself upon the floor he prayed fervently and said, 'How can I best serve my Maker?' As he lay prostrate on the floor he felt a touch upon his shoulder as light as that of a babe, and he heard a silvery voice, saying, 'Arise!' He arose, and there stood before him a beautiful angel, who said: 'Dost thou serve thy God?' And he replied, 'Yes.' Then, go serve thy fellow-man; administer to the sick, heal the afflicted; help those that are in distress.' And thus the medical profession had its origin. Our worthy guest to-night is almost an ideal of that Indian Prince of whom this legend tells. May he have many worthy successors."

Dr. Hobart A. Hare, of Philadelphia, responded to the toast, "Literary Medicine."

The last discovered fact;
The winnowed grain of thought,
Vividly portrayed in undying characters
By the art Divine.

He said that as he sat at the table this evening he could not help thinking that he, one of the youngest, if not the youngest speaker to-night, should bring from the effete East a graceful tribute of admiration to the honored guest of the evening. He thought it was a triumph for the so-called Western profession, which, after all, was not the Western profession of the United States, for the reason that every portion of this great country had sent by mail or by wire and by personal representation some one who bore a portion at least of the loving cup to Dr. Davis.

Speaking to the toast, "Literary Medicine," he said that there was far more in it than some thought. It enabled the members of the medical profession to compare notes and ideas. It improved the culture of men who wrote articles, and it improved the culture and learning of those, as a rule, who read those articles, but not always. In The Journal of the American Medical Association we had a great exemplar of what literary medicine should be. Literary medicine was in close touch with medical education It taught a large body of medical men to be general practitioners, and not to start out as specialists as soon as they had graduated. A great trouble with the medical profession of to-day is that there are too many men going into specialties because they knew nothing about ordinary medicine. Some one had well said: "I sought Happiness, and she constantly fled before me; weary, I turned to Duty's path, and Happiness sought me." It seemed to the speaker that Dr. Davis was a conspicuous example of that phrase. . . . We honor Dr. Davis because he represents to us professional ethics; because he represents to us duty well done; because he represents to us that greatest of all things, a great teacher; more than this, he carries with him, day by day, the thoughts of the minds and hearts of many more than are assembled here to-night, and he feels in his inner consciousness that he has achieved some things of which not only he is proud, but we are proud, and the American medical profession is proud. And therefore I repeat, as the representative of the so-called effete East, which has gained so much from the brawn and sinew of the mighty West, I come to-night to lay before you in your presence the loving tribute of our Eastern profession.

Dr. Edwin Ricketts, of Cincinnati, after referring to the good qualities of Dr. Davis, expressed the hope that he might yet be spared to see many years.

The last toast was responded to by Dr. Robert H. Babcock, of Chicago, it being, "The Physician in Public Affairs."

"For who is better fitted to study and correct the pathologic body politic?"

The speaker thought it was strange that physicians should be loth to enter politics lest they became defiled thereby, but he held that there was no class of individuals in the community who were so suitable to engage in public affairs as physicians. In the words of the toast, "Who is so suitable to study and correct the pathologic body politic?" Let the physician enter the field of politics, that he may curette away the part that is rotten. There was an ample field for the influence of medical men in a quiet way in political campaigns. We had an example of this in Kentucky, where the physicians throughout the State, by exerting their influence in a quiet way upon the politicians of the State, had rendered it impossible for a quack to practice or to advertise in the State of Kentucky. All honor to the State of Kentucky. He said we had among us some members of the medical profession who were engaged in political matters for the purpose of bringing about proper legislation along the right lines to curtail the so-called practice of medicine by quacks, charlatans, faith-healers, etc. There was ample room for the influence of physicians. But even if the physician had some ambition to hold office, it was right that he should, provided that his motives were pure. Physicians were needed in legislatures, not to support anti-vivisection laws, like Senator Gallinger, but to fight anti-vivisection laws, to fight anti-vaccination laws, and to obtain legislation for the benefit of public health. Perhaps the most brilliant example of the physician in politics is Rudolph Virchow What shall we say of our great American physician, Benjamin Rush? He was not only a great physician, but he was a member of the Continental Congress, and chairman of the committee appointed to consider the expediency of the Declaration of Independence. He had the honor of reporting favorably upon the Declaration, and it is thought that many of the phrases used in the Declaration of Independence emanated from Rush. Had he not won undying renown as a physician, he would have been immortal as a signer of the Declaration of Independence. The speaker said that there had been others and were others to-day who were engaged in public affairs not only with credit to themselves, but with honor to the medical profession, and to the welfare of their State. Some of these occupied comparatively insignificant positions, perhaps, but they were doing good work.

Dr. Babcock, after referring to the good work that had been done by Dr. Davis in public affairs, concluded by saying: "As an alumnus of the old Chicago Medical College, I call on you to rise, and, in that beverage which Dr. Davis loves and has continued to pledge his life, drink to his health."

At this juncture the entire audience arose, put the glasses to their lips, and, after the following sentiment expressed by Dr. Davis, drank to his health: "Here is to pure water, Nature's universal aseptic; it muddles no brain; it begets no anarchy; it sparkles on the dew-drop; it gives peace to the nation; it flows in the river of life, and it flows by the throne of God. Let us take it, not only as guests here, but for the whole profession of America."

The audience then arose and sang "Auld Lang Syne."

Societies.

COMING MEETINGS.

New York State Medical Association, New York City, Oct. 21-24, 1901.

Medical Society of Virginia, Lynchburg, Nov. 5-7, 1901.

Oklahoma Territory Medical Association, Oklahoma City, Nov. 13, 1901.

Southern Surgical and Gynecological Association, Richmond, Va., Nov. 19, 1901.

Mahoning County (Ohio) Medical Association.—At the meeting of this body at Youngstown, September 27, resolutions were passed in memory of Dr. Charles N. Fowler and John Eliot Woodbridge, members of the Society.

American Electro-Therapeutic Association.—This Association, which met at Buffalo, N. Y., September 25 and 26, for its eleventh annual session, elected the following officers: Dr. Frederick H. Morse, Melrose, Mass., president; Drs. Daniel R. Brower, Chicago, and Alfred T. Livingston, Jamestown, N. Y., vice-presidents; Dr. Richard J. Nunn, Savannah, Ga., treasurer, and Dr. George E. Bill, Harrisburg, Pa., secretary.

Muskingum County (Ohio) Medical Society.—This Society held its annual meeting at Zanesville, September 13.—The following officers were elected: Dr. J. C. Crossland, Zanesville, president; Dr. A. Dunn, Stovertown, first vice-president; Dr. G. Warburton, Zanesville, second vice-president; Dr. W. C. Batelman, Zanesville, secretary; Dr. C. E. Drake, Zanesville, treasurer, and Dr. C. U. Hanna, Zanesville, corresponding secretary. The Society voted to give a complimentary banquet, in November, to Dr. Edmund C. Brush, president-elect, Ohio State Medical Society.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Fifty-first Annual Meeting, held in Philadelphia, September 24-26, 1901.

President, Dr. Thomas D. Davis, Pittsburg, in the Chair.

(Continued from page 930).

SECOND DAY, MORNING SESSION.

Delegates from the N. Y. State Association.

The second day of the meeting was opened by the President and called to order at 9:30. Drs. Frederick Holme Wiggin and E. Eliot Harris, delegates from the New York Medical Association, were introduced. Dr. Wiggin said that their medical organization was formed by a federation of the county associations. One feature in the association was the divorcement of executive and scientific work; the former occupied usually the first day of their annual meetings, the latter occupying the remaining days. From an observation of the methods of the Medical Society of the State of Pennsylvania they had changed the publication of their Transactions, making it now a monthly journal rather than annual. The matter of giving polyclinic teaching to smaller county societies, as carried on in the Medical Society of the State of Pennsylvania, was also favorably commented upon. In view of the contemplated publication of a medical directory by the Pennsylvania Society similar to the one issued by the New York Medical Association, Dr. Wiggin said that the Directory had proven to be exceedingly valuable in medical circles, and promised to be successful also financially.

Dr. Harris said that Dr. Wiggin had spoken in accord with his own views, but emphasized the important factor that the county society was the central unit of the organization of the New York State Medical Association.

Dr. Wiggin further expressed the hope that the publication of such directories might suggest to the American Medical Association the publication of a National directory.

The Chairman of the Committee to suggest Changes to the By-laws, Dr. M. Murray Weidman, read the report, which was ordered printed and the Committee continued. Among the proposed changes is the provision for the formation of an executive committee which takes the place of the old Committee on Nominations, and is practically the legislative body of this Society. There is also the proposition for the collection and compilation of a list of all legally classified practitioners within the State.

Address in Medicine.

Dr. John B. Donaldson, of Canonsburg, said the present century's achievements promised to far outstrip the past. Internal scientific medicine with preventive means shall be the work of the medical world. Surgery, the brilliant half sister of Medicine, would go hand in hand with her in the crusade against disease, and that the profession might certainly look for other Jenners to arise who will eliminate many of the fatal but preventable diseases of our day. The hope was expressed that in the great Keystone State of Pennsylvania, the present century might see legislative bodies willing to legislate in the interests of indigent tubercular patients. The relief for these patients was an important field, to his mind, toward which the minds of our philanthropic millionaires might be directed. Ere long he believed that there would be an end to the so-called different schools of medicine, for all would be compelled to practice rational and intelligent medicine.

Dr. J. Dutton Steele, Philadelphia, read a paper on "Gastroptosis and Its Treatment."

Movable Kidneys; Their Effect on the Gastric and Intestinal Functions.

Dr. Boardman Reed, Philadelphia, maintained that nephroptosis was frequently one feature of a general sagging downward of a number of abdominal organs. Movable kidney is confined almost entirely to the female sex and is very prevalent. Prominent symptoms are pain or sensitiveness on pressure over the site of the displaced kidney and certain dyspeptic symptoms and nervous symptoms often result. In the severe cases with much pain complete rest in bed is advised, with later the support of a well-fitting pad and belt with special exercise and cautious massage to the abdominal muscles. Out-of-door air and tonic treatment, etc., are also urged. Where these measures are impracticable, or have failed, nephropexy should be done.

Dr. R. H. Gibbon, Scranton, regarded the application of a pad to a loose kidney a mistake. This had been pointed out by Edebohls, who laid great stress upon the fact of appendicitis having been frequently caused by a loose kidney displaced downward causing interference with the superior mesenteric vein resulting in congestion and inflammation. He believed that surgical treatment was the proper method in the majority of cases. The only external device of value in his opinion was the Cardigan corset, with the lacing reversed, i. e., beginning at the bottom.

Dr. Charles P. Noble said his personal experience had been limited to surgical treatment. When the mobility did not exceed two or three inches he believed the rest cure with general tonic treatment was useful. If the urinary symptoms are negative the case required little attention. Marked symptoms showing congestion of the kidney indicated nephrorrhaphy.

Enteroptosis.

Dr. John G. Clark, Philadelphia, dealt more especially with the mechanical part of the treatment. He felt that in the majority of cases the more conservative plan should be first tried. He had seen cases in which there was a general sagging of the pelvic floor with retrofixation, and in which not infrequently after operation the patient complained of the dragging sensation. He referred to the article by Webster, of Chicago, which he regarded of signal interest. Models were shown illustrative of the abdominal wall muscles looking from the front and from the back and the pathology demonstrated.

Dr. Gibbon, of Scranton, thought the fibrous sheaths of the muscles were at fault rather than the muscle tissue itself.

Report of Cases of Infective or Malignant Endocarditis.

Dr. A. O. J. Kelly, Philadelphia, said that during recent years our ideas concerning the nature of acute endocarditis had undergone considerable modification. Formerly it was customary to distinguish two forms of acute inflammation of the endocardium: one a benign, non-infective process, ending in the recovery of the patient, though usually with permanent damage to the valves affected; the other a malignant destructive infective process running a comparatively short course and ending in the death of the patient. It had long been observed that clinically the differential diagnosis between the two forms is sometimes attended with considerable difficulty. It had been ascertained that all cases of acute endocarditis are associated with, if not due to, bacteria; that the same bacteria are found in cases associated with ulceration as in those that are not, and the necessity for revision and modification of our conception of acute endocarditis became apparent to all. Three factors of diagnostic value were: 1, leucocytosis; 2, bacteriologic examination of the blood; 3, irregular heart murmurs.

Dr. A. E. Roussel referred to three cases of endocarditis occurring in his practice, two of which possessed features resembling those of Dr. Kelly's second case. In a girl of 19 the diagnosis of malignant endocarditis of the ulcerative type was confirmed by death. In many of the cases he thought it might be well to leave off the term "ulcerative" altogether; in many of the cases the tissue changes have gone as far as death without the presence of ulceration. The term "malignant" would seem to cover the ground. On the other hand, this term might be objected to because some of the cases got well; these were a small minority, however. A point of great interest in the second case was the progressive enlargement of the spleen. Leucocytosis was also marked. The third case was of interest in that it followed miscarriage and presented all the symptoms of a profound septicemia. The blood was taken from the vein, and Dr. Roussel emphasized the importance of taking a large amount of blood for examination bacteriologically.

Dr. J. M. Anders spoke of the difficulty in diagnosis in the two forms of endocarditis and emphasized the great importance of studying the cases minutely by the application of the most modern methods. He thought some value should be placed upon the presence of murmurs, even in so-called ulcerative endocarditis. Of more importance was the embolic phenomena. His constant rule was to carefully eliminate all affections simulating ulcerative endocarditis, particularly typhoid fever and the allied diseases.

Dr. James Tyson thought if the process were looked upon as a pyemic one in which the heart valves become the objective point of the bacterial effect the question would be greatly simplified.

A Few Notes on the Salts of Sulpho-Carbolic Acid.

Dr. Edgar Moore Green said that although the sulphocarbolates are supposed by some to be "inert," a few of them seem to be excellent intestinal antiseptics. The sodium, potassium and ammonium salts are those that have been most used by the author. One of the most satisfactory methods of administering the sulpho-carbolates is in pill form with enteric coating, because the drug then reaches the intestine and does its work at the proper place. He advocates sodium sulphocarbolate with acetanilid for the relief of headache associated with deranged digestion. Zinc sulpho-carbolate has been used with advantage in diarrhea.

Primary Abdominal Tuberculosis.

Dr. Lawrence F. Flick, Philadelphia, defined the condition in question as the primary existence of a tubercular colony in some tissue or organ within the abdominal walls. The general belief that tuberculosis began in the lungs was, he said, based upon the common experience that the first recognition of the disease is in the lungs; not until these organs are affected do the classical symptoms occur. The observations of pathologists and surgeons have proven that tuberculosis does frequently occur primarily within the abdomen; in what percentage is yet undetermined. Diagnosis is often impossible, and in this direction surgeons and gynecologists could aid much. Frequent discussions of the subject were urged. The question of treatment is still unsettled; men of the largest experience recommend early surgical intervention. As an alternative to this the building-up treatment is advocated by others.

Dr. Joseph Price said that if the surgeon could see these cases the treatment would be very simple and, as they often had occasion to think, very fortunate. For a number of years he had never refused to open the abdomen for intraperitoneal tuberculosis, whether ovarian, tubal, general, or whatever nature. He considers iodoform abundantly used of great value. The condition of abdominal tuberculosis he considered one which justifies excessive and undue liberty intraperitoneally, and which could be undertaken in no other condition. Iodoform should be used freely and drainage employed, either pelvic or general.

Dr. Mordecai Price expressed his belief that the infection occurred through the lymphatics and the blood, through some disorganization of the digestive tract with the food infected with tuberculosis. He had seen several cases apparently directly traced to the milk product. In diagnosticating intraperitoneal trouble where there was slow emaciation he believed it was the urgent duty of the surgeon to open the patient and investigate.

Dr. James Tyson stated that in the difficult diagnosis the tuberculin test presented an infallible test.

Dr. S. Solis-Cohen said that the use of iodoform in a clinical experience extending over a great many years had convinced him of its value in combating tuberculosis, internal or external. In the internal administration the secret of its efficacy is in the gradually increasing dosage, taking some three or four months to reach a maximum. The question of etiology was important. With the conflicting theories as to the transmission of human and bovine tuberculosis the etiology was unsettled. That human tuberculosis can be transmitted to cattle, or bovine tuberculosis transmitted to man, he thought there was sufficient evidence upon record from careful observations in the clinic and laboratory to make the profession very careful at this time not to give the impression that such transmission is not possible.

Dr. Flick, in closing, stated that the tubercle bacillus could enter the alimentary canal through other sources than food and milk; the bacilli entering the respiratory tract might lodge in the pharynx and be swallowed; these bacilli might be from a consumptive as easily as from food and milk. In the same way the germs could be carried into the bronchial glands, the thoracic duct and into the circulation. He laid special stress upon the value of iodoform and the preparations belonging to the same group.

Election of Officers.

The Nominating Committee made the following nominations, which were elected: President, Dr. F. P. Ball, Lock Haven; first vice-president, Dr. Walter Lathrop, Hazleton; second vice-president, Dr. A. S. Harshberger, Lewistown; third vice-president, Dr. R. W. Stewart, Pittsburg; fourth vice-president, Dr. J. K. Weaver, Norristown; secretary, Dr. C. L. Stevens, Athens; assistant secretary, Dr. W. B. Erdman, Macungie; treasurer, Dr. G. B. Dunmire, Philadelphia.

Dr. G. W. Guthrie, Dr. W. Murray Weidman, Dr. W. S. Foster, and Dr. A. P. Hull were elected Delegates to the House of Delegates of the American Medical Association, to serve for two years. Dr. W. T. Bishop, Dr. John B. Roberts and Dr. H. S. McConnell were elected Delegates to serve for one year. Sixteen Alternates were elected, and it was recommended by the Committee that Dr. William M. Welch, of Philadelphia, should be selected to serve as the fourth delegate to serve for one year, should the Society be entitled to eight delegates.

SECOND DAY—AFTERNOON SESSION.

Address in Hygiene.

Dr. E. B. Borland, Pittsburg, called attention to the need of special hospitals for the care of smallpox, diphtheria and scarlatina patients in population centers above 1000. Improperly prepared food was accounted responsible for much disease and intemperance. The advertisements of patent medicines, medical frauds and shams were accredited with the first suggestions to lives of crime and shame. About 20 per cent. of the commonwealth, it was stated, used normal water; 50 per cent. admissible, and 30 per cent. suspicious or dangerous. Preventive medicine was declared to be as exact a science as clinical medicine.

Histories of Three Accidents in Tapping the Chest.

Dr. J. C. Lange, Pittsburg, reported in detail three cases of accident; the first was one of instant death following the entrance of an aspiring needle through the seventh intercostal space at the posterior axillary line on the left side. The second patient was a man, aged 23, with history of croupous pneumonia two years previous, from which he had failed to regain his former excellent health. A cure was effected, and at the present time, two and one-half years after, there is no sign of thoracic disease, except an appreciable lack of fulness in the subscapular region as compared with the other side, and a difference in expansion of one and one-half inches in favor of the latter. The third case was that of a female, aged 58, with biliary cirrhosis, taken with acute pleuritis of the left side. Restoration to amount of health compatible with the liver lesion ensued, and in about a month she returned to her home in California. Death occurred sixteen months later without any complications of liver disease.

Reforms in Medical Education.

Dr. H. M. Shallenberger, Rochester, stated that the standard of equipment of the average graduate of medicine in the United States for the practice of his profession, is very low compared with the graduates in other departments of science or the polytechnic schools. A few questions and answers from papers submitted by graduates to the State Board of Examiners were given, which exposed blundering incapacity, lack of intelligent comprehension of the subject, bad construction of sentences, faulty spelling, etc., on the part of the student. Two remedies were suggested: 1, a preliminary examination of students, admitting only those who have had an adequate education; and 2, a change in the curriculum, giving a uniform standard in all colleges, embracing a comprehensive course of study and including all collateral branches, with special stress on clinical and bedside instruction.

Dr. E. B. Borland, Pittsburg, emphasized his belief in raising the standard of medical requirements. He believed, too, that the individual ought to be examined to ascertain his fitness for the study of medicine before it was undertaken. He thought the idea of examinations might well extend to members of faculties, and to members of the State Board of Medical Examiners. He was in favor of examining "all the way round, beginning with the student asking admission to the medical school."

Dr. J. C. Bateson, Scranton, was in favor of higher medical education. He believed that it should be general, that every one should be measured by a certain standard in order to practice the healing art, whether christian scientist, faith curist, osteopath, or of whatever sect.

Dr. Henry Bates, Jr., said that the responsibility of the Medical Society of the State of Pennsylvania is great, and not a member should be indifferent to his influence to attain a higher standard of medical education. Commercialism is rife, and permits the admission of men as students who are utterly incapable of comprehending the science of medicine. Defective and chaotic instruction is all too evident.

The Duration of Immunity from Diphtheria Antitoxin.

Dr. Henry D. Jump, Philadelphia, gave as his experience the injection of 500 units when the patient had been exposed. He had thus used the injection of the antitoxin in the cases of twenty children and no accident had occurred. It was his custom to isolate the sick person, disinfect the room, and remove well persons, each being given an immunizing dose. Illustrative cases were cited.

Lay Medical Education.

Dr. E. N. Ritter, Williamsport, believed that the school teachers are sufficiently trained to impart proper instruction to pupils in the lower and intermediate grades, but physicians should be employed to instruct advanced pupils in hygiene, physiology, human anatomy and venereal diseases.

Strength.

Dr. John M. Batten, Downingtown, had reference to a person with healthy organs, consequently a person in perfect health. Such a parent governs the sex of his or her offspring; if the father were strong, the sex of the offspring will be a female; if the strength of the mother prevail, the offspring will be a boy.

The Veriform Appendix.

Dr. Edmund W. Holmes, Philadelphia, presented this paper, with accompanying specimens, which was based mainly upon the examination of 110 adult appendices. He recounted the four varieties of ceca according to Treves, and in the 110 cases, he had found of the first variety; 1 of the second; 96 of the third, and 12 of the fourth. He pointed out the natural tendency of the cecum to swing round the ileo-cecal valve as a pivot, carrying the appendix toward the left. Toward the left, therefore, should search be made for the base; the ileo-cecal valve itself is a valuable landmark in cases of doubt, when the usual band is indistinct, as the appendix may be found close to it or even behind it or without a meso adherent to the postcecal wall. The appendicular artery, he explained, is usually single, running on the edge of the meso, but there may be two or more branches coming directly from the posterior trunk of the ileo-colic, requiring separate ligation. The length of the displacement of the appendix, or mayhap displacement of the cecum and colon en masse, may account for anomalous symptoms. The palpation of the appendix through the abdominal wall may be fallacious, owing to contact of the fingers with the psoas magnus muscle, or to the displacement of the colon, cecum and appendix to the median line.

The Doctor's Fee; Is It Fixed and Definite?

Dr. L. J. Lautenbach said that the doctor's reputation, skill, time consumed, risk incurred, and responsibility assumed influenced the amount of his fee. It is also controlled by the patient's standing, his obedience and the result of the treatment, as well as the general, social and financial condition of the community and the reputation and skill of his brother doctors. One influence in the reduction of the fees of the family doctor was the fact that fraternal societies supply the doctor and medicines to members at a nominal cost. Fees apparently high are usually determined by elements unobserved by the public. It was said that a lawyer or an architect might get fabulous prices, yet should a doctor charge a man $5,000 for saving him from the grave, but few would gratefully pay it. A fair price should be charged in every case, and such fees, if not paid, should be collected.

Therapeutic Notes.

Dr. Linnaeus Fussel, Media, called attention to a few remedies which appeared to him of great value.

Some Respiratory Conditions Dependent Upon Gout and Obesity.

Dr. J. M. Anders, Philadelphia, stated that the abnormal conditions presented by the lungs in obesity has not received the attention it deserves. The symptom dyspnea, so common in the anemic variety of obesity, he attributed largely to mechanical interference with the respiratory function, though muscular and hematologic changes shared in the causation. In the plethoric form of polysarcia the dyspnea is often surprisingly slight. Pain in the subscapular and intrascapular muscles may be acute, and it deserves attention. One patient had described it as a feeling as though the "flesh had grown fast to the bones." The pain may be localized, but commonly extends across the back. Hyperemic bronchitis, with troublesome cough and copious mucoid expectoration, occurring in over-fatness was described. Closely connected with this bronchitis is asthma, due in great part to transient insufficiency of the heart muscles; there is also an asthma in this connection, due to gastric disturbance, particularly seen in patients of gluttonous habits. His tentative conclusions concerning the relation of asthma to polysarcia were: *a.* That asthma occurs in about 5 per cent. of cases of obesity; *b.* That it only occurs in extreme polysarcia; *c,* that there is a gouty state or history in most cases in which true asthma is secondary to obesity; *d,* that about 50 per cent. of the cases are curable by overcoming the causative condition. In conclusion attention was called to chronic bronchitis, associated with latent gout or a lithemic state. For success in the management of the cases, the prime requisite is to include the recognition of the cause under the head of diagnosis so that the line of conduct may be adapted to it—the lithemic state.

A Medical Examination as a Prerequisite to Marriage.

Dr. J. C. Bateson, Scranton, referred to the many thousands of unhappy marriages contracted every year. Instead of regarding these as the natural result of violated physical law, many good people piously criticise the severity of Providence. Hereditary influence is too lightly considered by society. The question has been agitated by the writer since 1895 and he has much satisfaction in the knowledge that the scientific regulation of marriage has been proposed and acted on in several state legislatures. He believed that the only logical and effectual course to uproot this social evil is in the enactment and enforcement of a law requiring all applicants for marriage to pass a medical examination, before an authorized board composed of men and women and containing at least two physicians.

The Diagnosis of Lesions of the Aortic Orifices, with Special Reference to Functional Aortic Insufficiency—Pseudo-Leukemia, with Enlargement of the Liver and Spleen, Due to Lymphatic Tuberculosis—A Case of Typhoid Fever Complicated by Noma, with the Demonstration of Diphtheria Bacilli in the Necrotic Area.

Dr. Joseph Sailer, Philadelphia, in presenting these papers gave a mere outline of the second case. He referred to General Sternberg's investigations in this condition. He had found in all, fifteen cases in which the lymph glands showed peculiar histologic enlargement and tubercle bacilli could be found by the usual staining method. These investigations were not the first, but the most important, in that, here the first systematic effort had been made to prove that pseudo-leukemia of a certain peculiar type was not a blood disease, but an infectious disease, and that the infection was produced by the tubercle bacillus. The number of cases reported is only about thirty in all. In the short space of six months six such cases had come under Dr. Sailer's observation, in four of which it was possible to confirm the diagnosis before death; in two by the autopsy. The general features of the cases were given. In one case the liver was distinctly enlarged for two years and in nearly all cases it was exquisitely tender. The temperature chart exhibited, showed a singular irregularity occurring nowhere else except in chronic pyemia, the cases being differentiated by the absence of leukocytosis. The pathologic changes were given. He called attention to this group of cases, peculiar, because very few had been recorded, but he thought with those who had written upon the subject that they escape recognition because the pathologic changes are not invariably those indicating the existence of tuberculosis and the clinician is probably satisfied with the diagnosis of leukemia or Hodgin's disease.

(To be continued.)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Local Treatment in Chronic Prostatitis.

A. H. Leuf, Philadelphia, in *Med. Council,* states that for local treatment of the prostate, those preparations containing iodoform or iodol or ichthyol are efficient pain relievers and reducers of congestion. In diffuse chronic inflammation of the prostate, larger quantities of these drugs may be used per rectum, and, if there is much pain, especially if so severe as to cause loss of sleep, these may be combined with opium and belladonna. The following is recommended by him as giving prompt relief:

℞.	Iodofórmi		
	Ichthyol, āā	ʒii-iv	8-16
	Ext. opii	gr. xii	75
	Ext. belladonnæ	gr. iii	20

M. Ft. suppos. No. xii. Sig.: Insert one into the bowel as often as may be needed to relieve pain.

He further states that counter-irritation may in some cases serve a useful purpose when applied to the perineum and hypogastrium in the form of sinapisms or blisters; however, such procedures should be omitted in the treatment of such conditions in the aged.

Treatment of Malarial Hepatitis.

Lemanski, as noted in *Amer. Med.,* advises the avoidance of *alcohol as of prime importance in the treatment of malarial* hepatitis. Arsenic, quinin and the alkalies are of great service used as follows:

℞.	Sodii cacodylatis	gr. ⅛	008
	Pulv. cinchonæ		
	Sodii bicarb., āā	gr. viii	50

M. Ft. cachet No. i. Sig.: One such, three times a day. He recommends at the same time free purgation and prescribes the following for that purpose:

℞.	Hydrag. chloridi mitis	gr. xii	75
	Pulv. cascaræ		
	Pulv. rhei, āā	gr. ix	55
	Pulv. belladonnæ	gr. i	06

M. Ft. capsulæ No. iii. Sig.: One capsule every fifteen minutes in the morning.

To Check Gastric Fermentation.

The following is recommended by Ewald to prevent the process of fermentation in the stomach:

℞.	Resorcin	gr. lxxv	5
	Bismuthi salicylatis		
	Pulv. rhei rad.		
	Sodii sulph., āā	ʒiiss	10
	Sacch. lactis	ʒiv	15

M. Ft. chart. No. i. Sig.: One half teaspoonful twice daily.

Local Anesthesia in the Ear.

Dr. H. Dupuy, New Orleans, in *Laryngoscope,* recommends the following as an anesthetic for the drumhead in order that a free incision of the membrana tympani may be made:

℞.	Cocainæ	gtt. v-x	30-60
	Alcoholis (pure)	ʒi	4
	Olei amlin	ʒi	4

M. Sig.: Drop a few drops into the ear. This will produce complete anesthesia in a few moments.

Furuncle in the Ear.

Furuncles originating in the aural passage give rise as a rule to excruciating pain and earache. The *Med. Record* publishes the following for local use under such circumstances:

℞.	Zinci oxidi	ʒi	4
	Acidi carbol.	gr. x	66
	Vaselini albi	℥i	32

M. Ft. unguentum. Sig.: Insert a cylindrical tampon of cotton wool, covered with the ointment, into the canal. This tampon should be large enough to produce considerable pressure. The greater the swelling, the greater should be the pressure made by the tampon. The pain is at first severe, but disappears after a few moments; if not, insert smaller tampon. Before tamponing, use antiseptic douche and repeat daily.

The Proper Method of Using Spartein.

S. Solis-Cohen, in *Amer. Med.,* states that spartein occupies *a high place* among cardiac tonics and diuretics. He states, however, that the general practitioner is disappointed many times in its use because of improper dosage and methods of administration. In his *opinion,* in order to obtain the full effect of spartein, especially as a diuretic, it is necessary to begin with rather large and oft-repeated doses. For example, grain one-half to grains two may be given hypodermically every second hour, for three or four doses; after that the drug may be given by the mouth in gradually lessened quantities and at increased intervals, until after three or four days the patient is taking grain one-half three times a day by the mouth, and after a week's time ¼ grain three times a day, with now and then an administration of one or two large doses. In following this method of administration the effect upon pulse, in its tension and frequency, as well as the cardiac force, must be watched closely to avoid overdosing or underdosing. When the patient is not bedridden such large doses are not to be advised; one should then begin with ½ grain four times a day and increase or diminish the dose according to the effect, keeping in mind that the point is to get the patient rapidly under the influence of the drug by the maximum dose tolerated and then prolong the effect by the minimum dose effective.

Tannin and Bromin in Treatment of Pruritus.

Joseph, in *Med. Standard,* states that an ointment containing bromin and tannin is of great service in the treatment of all forms of pruritus. The bromin, according to his statement, is used for its anesthetic properties and the tannin for its astringent effects. He prescribes an ointment composed of bromin 20 per cent. and tannin 40 per cent. He states that the action of this ointment is increased by the alkaline secretion of the skin, without producing any irritation. He uses as a base a 10 to 30 per cent. jelly.

Use of Menthol in Gastritis.

G. E. Campbell, in *St. Paul Med. Jour.,* has used menthol in cases of gastrodynia eructations, distension, cardiac distress and vomiting. He states that the object in such conditions is to neutralize the excessive acidity and relieve the hypersensitiveness of the organ. He recommends, to meet these indications, the following combination:

℞.	Menthol	gr. ⅛ to ii	008-12
	Sodii bicarb.	gr. x-xv	66-1

M. Ft. chart. No. i. Sig.: To be given one-half hour before meals. He recommends the administration of pepsin after meals in some form.

Cocain in Treatment of Pain in Gastric Cancer.

The following combination has been recommended in relieving the pain in cases of carcinoma of the stomach:

℞.	Cocainæ hydrochlor.	gr. ss	03
	Morphinæ hydrochlor.	gr. 1/6	01
	Aq. calcis	℥iii	96

M. Sig.: One coffeespoonful every hour in a tablespoonful of iced milk.

An ice bag may be placed at the epigastrium to aid in relieving the pain.

Treatment of Croupous Pneumonia.

A. Pitzold, in *Deutsches Arch. f. Klin. Med.* states that he has successfully employed quinin in the form of subcutaneous injections for the past three or four years in the treatment of pneumonia. He is of the opinion that it acts as a sort of antitoxin for the poison, as such marked improvement in the general condition of the patient takes place. He used daily injections of seven and a half grains (.5) of the hydrochlorate of quinin. This is the most soluble salt of quinin, being soluble in 34 parts of water.

Sodium Cacodylate in Chorea.

Lannois, in *Rev. de Ther.*, has used sodium cacodylate instead of arsenic in the treatment of three cases of chorea. He used the drug hypodermically, beginning with grain one-third and increasing to grain two-thirds. He reports that all the cases recovered in from one to three weeks.

Treatment of Chronic Rheumatism.

℞.	Acidi arsenosi	gr. iii	12
	Pulv. guaiaci	ʒiii	12
	Pulv. capsici	ʒss	2
	Pil. aloes et myrrhæ	ʒiii	12

M. Ft. pil. No. xx. Sig.: One pill twice daily.

Treatment of Psoriasis.

Morgenstern, as stated in *New York Med. Jour.*, gives the following prescription to be used locally in the treatment of psoriasis:

℞.	Acidi salicylici	gr. xii		75
	Sulphuris precip.	ʒi	4	
	Zinci oxidi			
	Amyli, āā	ʒii	8	
	Vaselini	ʒv	20	

M. Ft. ung. Sig.: To be applied locally once or twice daily.

Treatment of the Toxemia of Pregnancy.

To employ intelligent treatment in the foregoing condition, good judgment and a thorough knowledge of the actions of drugs must be had, especially in those cases where organic disease of the heart is present. The elimination and the eliminating organs must be carefully watched and frequent estimations made of the work done by the kidneys. Marx, in *Med. Rec.*, states that the amount of urea should be estimated often as it is always diminished in true toxemia of pregnancy. He further states that progressive diminution of urea elimination with or without albuminuria is an indication for the induction of premature labor. He recommends as diuretics in such conditions the refrigerant diuretics of the sodium class (not the potassium salts which are too depressing) with an infusion of buchu or triticum. Digitalis is contraindicated because of the digitoxin present, which is a renal irritant. The most valuable drugs are the vasodilators, such as nitroglycerin amyl nitrite and sodium nitrite. As true heart tonics, he prefers spartein and the caffein salts and strychnin, to be used when there is a low tension pulse.

J. C. Webster, Chicago, in those cases in which approaching toxemia demands rapid induction of labor and which are complicated by organic heart lesions—such as a double mitral lesion—uses chloroform as an anesthetic, to which is added a small amount of amyl nitrite. In his opinion the great danger to the patient is in the third stage of labor, and in this stage he orders an inhalation of pearls of amyl nitrite in order to secure the most complete dilatation of the peripheral vessels. Under such circumstances lacerations may be a power for good in relieving pressure by bleeding and no measures should be taken to produce contractions of the uterus, consequently the administration of ergot is non-indicated.

The Use of Ergot After Labor.

The *Lancet-clinic* states that the value of this drug has been overestimated, that it has not stood the claims of its adherents. The question is asked, why use ergot in normal labor when viability of the mother is good and the fundus of the uterus can be felt as a hard firm ball over the symphysis? It is stated by the author of the foregoing that he has used ergot about five times in the last one hundred cases and has practically discarded it on account of its disagreeable taste, its tendency to cause nausea and the unreliability of its action. Its effects are not constant. Many authors claim that it limits the danger to postpartum hemorrhage, diminishes the force of after pains and lessens the tendency to accumulation of putrid material in the uterus and thus lessens the tendency to puerperal infection. Putrid material in the uterus after labor generally means infection contracted at the time of delivery and all the ergot at our command could not do the good that a thorough aseptic washing of the uterine canal would produce.

Treatment of Alcoholism.

Dr. J. L. Howard, in *Med. Council*, recommends the following to be substituted for alcohol in habitual drinkers:

℞.	Tinct. nucis vomicæ	℥ss	16
	Tinct. capsici	℥i	32
	Ext. lupulini flu.	℥iii	96
	Inf. gentianæ comp.	℥iss	48

M. Sig.: One dessertspoonful three or four times daily, well diluted.

Medicolegal.

Fifteen Thousand Dollars for Death of Physician.—The second appellate division of the Supreme Court of New York holds, in the case of Ericius vs. the Brooklyn Heights Railroad Company, that it can not be said that an award of $15,000 damages is excessive, for causing the death, through negligence, of a physician about 50 years old, who was earning in the practice of his profession, $175 a month.

"Serious Illness" in Contract of Life Insurance.—The Supreme Court of South Carolina accepts, in the case of Drakeford vs. the Supreme Conclave, Knights of Damon, of the construction, in a contract of life insurance, of the term "serious illness," used in the application, as meaning something that injures a person permanently—any permanent impairment or material impairment of health, it being said that a sickness might be very bad and very sad, and yet not serious.

Admissibility of Non-Expert Opinion as to Imbecility.—A non-expert witness who has had adequate means of becoming acquainted with the mental state of a person whose sanity is in issue may, no doubt, the Supreme Court of Louisiana says, in the case of State vs. Smith, give his opinion, based upon facts to be stated by him, as to whether such person was insane at the time of a specific occurrence. And it thinks that such an opinion would be admissible, subject to the limitation mentioned, upon the question whether the person inquired about had been insane or had been an imbecile throughout his life. But, without the limitation, it would not be admissible. In other words, the court holds that the opinions of non-expert witnesses as to the imbecility or insanity of the accused are admissible only in connection with testimony as to the facts upon which such opinions are predicated.

Occurrences at Medical Examination as Evidence.—It does not need the citation of authorities, the fourth appellate division of the Supreme Court of New York says, in the personal injury case of Jones vs. the Niagara Junction Railway Company, to show that evidence as to what takes place upon the medical examination of a party as to the injuries which he has received, so far as they are the natural expression of pain or inability to do certain things, is competent. It is quite true, it adds, that to a certain extent these expressions may be feigned, but it is for the jury to say, upon the testimony in the case, whether they are the usual actions of one who is expressing involuntarily the sensation that he feels, and so far as they are simply that they are competent, and their admission does not violate any well-settled rule.

Summoning of Surgeon by Conductor of Wrecking Crew.—The Appellate Court of Illinois, Third District, says, in the case of the Chicago & Alton Railroad Company vs. Davis, that the rule is well settled in this state that where an accident happens to an employe of a railroad company, the local surgeons of the company are not in the vicinity, and the condition of the injured man requires prompt medical attention, that the representative of the company in authority at the time and place of the injury has the right to employ medical assistance. If a doctor is sent for by such representative of the company, and, at his instance, performs professional services for the injured employe, the company will be liable to pay for such service. So, where an employe was badly injured and an emergency for prompt medical aid existed, and the man in supreme authority at the time was the conductor of a wrecking crew, who directed another man to call a doctor, and the latter performed the service in response to such call, the court thinks that the physician had a clear right of recovery for such services in an action against the railroad company.

Powder Marks and Medical Jurisprudence.—It is competent, of course, says the Supreme Court of Alabama, in the murder case of Timothy vs. State, to put in evidence passages from standard medical works pertinent to wounds and personal physical conditions under inquiry. But a passage from a work on medical jurisprudence containing an account of certain experiments made by two third persons with guns at various distances to determine how far from the target the weapon would have to be to leave no powder marks, and the conclusion of the author from such experiments, the court does not consider of that character. It says that it does not pertain to the science of medicine or surgery. Men of those professions are no more competent to make such experiments and draw conclusions therefrom than other men, and their opinions in the premises stand upon the same evidential plane as the opinions of laymen, and are to be received in the same way and under the same circumstances. Such opinions are never admissible unless the persons giving them are shown to be experts, and then by the word of mouth of such experts under oath. Wherefore, the court holds that it was error to permit such an extract from a work on medical jurisprudence to be read in evidence to the jury in this case. It says that it did not appear that the author was an expert on powder marks, nor that the two experimenters referred to were, and, conceding them to have been experts, they were not sworn before the jury. As for the experiments themselves, it is well settled in this court, it says, that, had the two experimenters been sworn on this trial, they would not have been allowed to depose to them.

AMERICAN.

2. **Amputations.**—The special conditions under which amputations are justifiable are noticed by Cowan, who says that in every case of severe injury there are three questions usually confronting the surgeon: 1. The treatment of shock. 2. When to amputate. 3. Where to amputate. First he would consider the condition of shock as one of anemia and nervous exhaustion and treat it accordingly with nitrate of strychnia hypodermically, or nitrite of amyl and hot saline solution, which is one of the most valuable means we possess for combating shock, possibly the most valuable. In deciding when to amputate, the surgeon must largely be governed by the degree of shock, systemic and local, meaning by the latter the devitalizing or lowering of resistance of tissue in the vicinity of the injury. In profound systemic shock, operation almost invariably results fatally. He is opposed to immediate amputation in the large proportion of cases, always in profound shock, and not infrequently in the absence of systemic shock, and in certain cases where we are in doubt as to the extent of the injury to contiguous tissue. The question where to amputate is a very grave one to the patient and the rule that every inch of tissue should be saved that is possible, is not without its exceptions. The great desideratum, na-

turally, is to produce the most useful possible stump and in injury about the knee it may be better surgery to go just above the point, enabling the patient to wear an artificial limb with more comfort than in case of disarticulation. In dealing with injuries to the hand or fingers, the utmost conservatism should be employed, every finger or part of a finger that can be should be saved. In operations undertaken on account of pathologic conditions, among which he includes infections, gangrene, osteomyelitis, osteosarcoma, etc., amputation may be necessary. He has used local analgesia with cocain in a number of amputations, and recommends it especially where shock is grave and immediate amputation is deemed advisable. The technique of the operation is described at length and in too much detail to be reproduced. He thinks the circular method for amputation superior, as having advantages over the older transfixation operation. A large muscle flap is in no way desirable.

3. **Laceration of the Cervix.**—The special points made by Beyea are the factors of selection in operation, including the proper selection of cases, preparation for operation, attention to certain essential operative details and the selection of the proper operation for the individual cases. The selection of the cases is the most important. The chief contraindication to operation is the presence of pelvic inflammatory trouble outside the uterus, such as tubal and ovarian disease. There are also other lesions that must be recognized and repaired before perfect health can be restored. Treatment should be employed to prepare the parts for the operation. In regard to the details of the technique of trachelorrhaphy he only alludes to a few points. All cicatricial tissue should be thoroughly removed, no portion or part of a Nabothian cyst should be left in the line of denudation. Sutures should be accurately and evenly placed. If good asepsis is practiced union will never fail. The sutures should not be too tight nor too loose, but just enough to secure accurate and firm apposition. If there is the least suspicion of malignant disease the surgeon should not await developments, but the suspected tissue should be thoroughly excised.

7. **Cancer of the Rectum.**—Hupp's article is largely a review of the literature, though he reports several cases of his own. The latter part of the paper is taken up with the revision of the statistics.

9. **Intracranial Injections.**—This method is advocated by Anderson in a number of conditions and he summarizes his personal experience in the following: 1. It is of no advantage in acute bronchitis, at least during the congestive stage. 2. It is of distinct advantage in subacute and chronic bronchitis. 3. It is of positive benefit in bronchiectasis. 4. It is valuable in pulmonary tuberculosis, relieving many of the symptoms, especially those due to secondary infection. 5. It quickly relieves the distressing symptoms of asthma. The amount of relief and the permanency depend largely upon the predisposing and exciting causes. 6. It in no way interferes with other lines of treatment. 7. The writer has never seen harm follow its use, although in a very few instances it excited severe coughing for a short time.

11.—See abstract in The Journal, xxxvi, p. 1652.

12.—Ibid.

13. **Symphysiotomy.**—Jewett concludes as follows: Symphysiotomy is still a useful operation within a limited range of pelvic contraction. It is suited to conditions in which only very little additional space is required for delivery. It is a valuable resource, therefore, in cases in which forceps unexpectedly proves inadequate. Axis traction forceps with the aid of posture should always be tried before resorting to symphysiotomy. Its results would be much improved by restricting it to pelves with a conjugate of not less than 7.5 cm.—3 inches—in simple flattening or 9 cm. in general contraction. Under equally favorable conditions its total mortality should be no greater than that of Cesarean section. When the pelvic space permits it should replace the Cesarean operation in the presence of exhaustion. It may be elected primarily as an alternative of Cesarean section when the operator can be assured that the degree of obstruction is well within its safe limit. Here the choice of operation is a matter of individual preference. Within its proper field symphysiotomy is better than Cesarean section for an operator of little experience in abdominal surgery.

14. **Cesarean Section.**—The conclusions to which Reynolds has been led by experience are: 1. That Cesarean section performed late in labor or in the presence of infection of the uterus or other complicating constitutional conditions, has been shown by the experience of almost every one who has tried it to have so high a mortality as to be totally unjustifiable when performed in the interests of the child alone. 2. When Cesarean section is performed on a healthy woman under otherwise favorable circumstances for merely mechanical indications in skilled hands, there is no mortality other than the fractional percentage incident to all considerable operations per se. 3. The inconveniences and high morbidity rate of symphysiotomy make it distinctly inferior to section as the operation of choice, but it is the operation which, as compared with craniotomy or prolonged and forcible high forceps work without it, involves almost no increased risk to life. He therefore believes it to be an operation of choice in a somewhat limited number of neglected cases (those where Cesarean section is ruled out) in which the pelvic contraction is within the range and where the extraction of a living child without symphysiotomy is difficult or impossible, but after symphysiotomy, is safe or easy. 4. The induction of premature labor for contracted pelvis causes so high a fetal mortality as to be unwarranted, as compared with the performance of Cesarean section at the beginning of labor and in favorable cases. His belief in the safety of early section is based on a personal experience in 19 cases and observation of the literature for nearly ten years. His belief as regards symphysiotomy is largely from the experience of others and a study of the literature. Pelvimetry is our only means of diagnosing the existence of deformity and contraction, and he thinks it will come to the point where it will give us an accurate knowledge of the pelvis. He recommends careful pelvimetry during pregnancy in those multiparas whose previous history is that of difficult labor and in all primiparas, and, in conclusion, urges his personal belief that no man is justified in permitting Cesarean section as a last resort or upon infected or otherwise constitutionally ill women for the sake of the child alone, but that it can be done in the beginning of labor with a healthy woman with even less risk to either mother or child than is involved by unusually high forceps work.

15. **Heart Disease.**—The summary of Reed's paper is given as follows: 1. Cardiac disease is often due to autointoxication, especially to poisoning by the alloxuric bases; 2, cure or amelioration in such cases requires at first, in addition to an appropriate diet, not too nitrogenous, the utmost practicable rest of the crippled organ. This cardiac rest may be further promoted by very gentle exercises which dilate the capillaries without taxing the heart; 3, the Nauheim method of treatment spares the heart by dilating the too contracted arterioles in two ways—(*a*) by stimulating the peripheral circulation through carbonated saline baths; and (*b*) by massage and forms of exercise (*Widerstandgymnastik*) so mild as not to quicken the pulse.

16. **Social Aspects of Dermatology.**—In this third lecture Morris describes certain conditions such as ringworm, which he thinks was possibly imported from India. He goes over the history, pointing out that Gruby had, in 1844, published an article on the organism which was overlooked until it was rediscovered by Sabouraud about fifty years later. The number of organisms producing this is noticed and the author's own results given. His investigations have led him to the conclusion that there are at least two distinct fungi which may cause ringworm, one with small spores and the other with large ones. The large spored fungi attack the root of the hairs and go downward, and also attack the body in the region of the beard and elsewhere. The small spored variety attacks the scalp

chiefly, is in children almost exclusively and produces a very refractory condition indefinite in duration. The prognosis of scalp ringworm is not altogether a satisfactory one, though, as a rule, it comes to a spontaneous end after puberty. He believes that children affected this way should be treated in special schools apart from others, to avoid spreading the disease. Favus is also a disease which has undergone some changes as regards our views of it. It is much more serious than ringworm and exceedingly unpleasant. He thinks it should be restricted by legislation. The immigration of persons bringing it should be checked. Like ringworm it can only be stamped out by properly organized methods of medical and sanitary repression. He concludes by mentioning some unimportant forms of disease caused by vegetable fungi, like tinea versicolor and erythrasma, both of which are trivial.

17. **The Gonococcus.**—Eastman's article is a lengthy and elaborate description of the gonococcus and its toxins and seems to be quite thorough. It is too full to be abstracted. He believes that gonorrheal urethritis, once cured, affords some degree of immunity against subsequent attacks.

18. **Brain Disease.**—Eskridge sums up this series of articles which has been running through several preceding numbers in substance as follows: A careful study of temperature, pulse and respiration will give much valuable information, aiding in the diagnosis and prognosis of certain diseases of the brain. Careful and reliable records are required, needing much time and patience. Nurses are totally incompetent for such detailed work, unless specially trained to it. The change in the character of respiration rather than in its frequency is one of the first positive symptoms of intracranial organic disease, especially of tuberculous meningitis. A respiration that is more frequent while the patient is asleep or unconscious than during the waking or conscious moments, is very strong evidence of organic brain disease interfering with respiratory centers. Apoplexy due to hemorrhage is attended with greater disturbance of the body temperature soon after the stroke than is the case when the apoplexy is due to thrombus or embolus. The temperature disturbances in apoplexy due to hemorrhage, especially if attended with hemiplegia, are a slight fall of the axillary heat within an hour or less after the occurrence of the hemorrhage, the fall being a little greater on the paralyzed side. If reaction has occurred (eight to twelve hours on the average) we see a slight rise of temperature a little greater on the paralyzed than the opposite side, elevation from one-half to 2 or 3 degrees above normal for the next few days, the temperature remaining a little higher on the paralyzed side than the opposite side for a week or more in cases of complete hemiplegia; later, the temperature is slightly lower on the paralyzed side if trophic disturbances occur. In apoplexy from thrombus or embolism there is scarcely any appreciable temperature disturbance before the end of the second day, except in the severer cases, and then slight. In the majority of these cases there is no marked variation of temperature from the normal at any time, so that temperature disturbance the first day points very strongly to hemorrhage. Considerable disturbance of temperature, beginning from the second or fourth day, is significant of thrombus or embolus, and indicates extensive softening and an unfavorable prognosis. If the temperature of the paralyzed side remains higher than on the opposite side for several weeks after the occurrence of apoplexy from any cause, it indicates that softening or inflammation of the brain is progressing and the prognosis is very grave. It is premature to attempt to arrive at any definite conclusions from the study of the temperature, pulse and respiration in brain traumatism. This class of cases deserves a more detailed study of all their symptoms and it is probable that if they were classified and grouped according to the severity of the injury and the character of the symptoms, a careful comparison of the temperature, pulse and respiration would lead to important conclusions. In regard to the traumatic class of cases it seems we are justified in making the following tentative statements: 1. All cases of injury to the head in which the temperature does not reach normal or slightly above a few hours after the receipt of injury will probably prove rapidly fatal. The higher the temperature the greater the probability is that contusion or laceration of the brain and membranes is the more important factor in the case than intracranial hemorrhage. The greater the variation of the temperature from normal, either above or below, the worse the prognosis. 2. A rapid, weak, intermittent and irregular pulse indicates danger. A pulse that is first slow, but soon after becomes quite rapid indicates that the brain power is being overwhelmed by the intracranial lesion, and justifies a bad prognosis. 3. The exceedingly slow and intermittent respiration (8 to 10 to the minute) indicates a lesion at the base in the posterior fossa. The slower and the more pronounced the intermission of respiration the greater the danger of sudden death. A respiration at first nearly normal in frequency but soon after becoming quite rapid, indicates a rapidly fatal case.

20. **Osteomalacia.**—Brennan suggests that osteomalacia of the mother is due to the absorption of calcium salts by the fetus indirectly by taking from her blood the pabulum which she requires to build her own tissue. In the case of a poorly-fed woman, she holds, this would easily occur. We may say then, according to this theory, that osteomalacia is a condition the result of the poverty of calcium salts in the blood of the mother by which the osseous tissues are starved by the fetus assimilating all the valuable salts. If the diet were rich in salts there would be sufficient for both.

21. **Medical Education.**—Burrell calls attention to the value of experience, which, nevertheless, is not the only method of obtaining knowledge and can be supplanted in some measure by the student having a foundation firmly laid by scientific methods in laboratories for research work, hence the value of laboratories. The special practitioner will have his foundation laid in these, and carry the training he has there received to individual patients. The uses of the clinical laboratory are stated by Burrell as follows: 1. The habit which the student will form of examining clinical products in each individual patient as he presents himself. 2. The training of students to apply their abstract scientific knowledge to the concrete example of a patient. 3. The stimulus to acquire knowledge at first hand, which will not alone be felt in his laboratory work. 4. The impetus it will give to research. The writer also says that the compensation and the position of the teacher of medicine at present are not what they ought to be. He is obliged to give his time and attention 1, to his living, 2, to his hospital work, and 3, to his teaching. The matter will not be improved until the medical schools make a teaching position the principal object of a man's life. Burrell considers that the value of lectures, recitation, demonstration, etc., is still undetermined. There are certain subjects that are always best presented by lectures, and clinics will always be of great advantage. Extramural teaching should be carefully tried in all large centers of population. Graduate instruction at the present is not sufficiently scientific. The doctor goes to get therapeutic tips, the latest dodges in operative technique and the reputation of having the latest scientific facts. The graduate instruction should be planned so that real knowledge can be obtained in the shortest possible time. The function of the modern medical school is that of a university of medicine, and should fit the students for the practice of specialties and biologic work as well as for general practice. What the curriculum should be is yet a question. He gives a diagrammatic showing and criticism of the curriculums in four leading schools, not, however, designating the institutions. He summarizes that every school of medicine should establish its curriculum not depending on the wishes of the head of each department, but planned for the good of the student, and should establish in each of its departments the minimum required course for the average student. During the fourth year of instruction the work should be essentially elective and optional in order that students can prepare themselves for the special lines they are to engage in. Improvement in the method of instruction can best be secured by active competition. This can be obtained by the medical schools of the country adopting a standard of minimum required work.

At what period this minimum required work should cease is open to argument.

22. **Heart Disease.**—Edes commences by remarking that the time is not long past when the prognosis was based upon the observation of cardiac murmurs almost exclusively, and the average practitioner is supposed still to be in bondage to the old ideas. He describes the physiologic action of the heart and shows that the line between the healthy acting and inefficiently active heart can not be sharply drawn, but has a varying margin which can only be told with precision by experiment, which may be dangerous. It is only in the increase of muscle power and in regulating it so that it can be economically used that the best results are to be obtained. He dwells on the importance of the trained touch to diagnose the pulse, and, while it is not possible to diagnosticate actual degeneration of the cardiac muscle, it can be done with sufficient probability for practical purposes. He considers the term "heart failure" a proper phrase for the state of things when the margin has been passed in the wrong direction. It is objectionable only because it is so easy to misapply. In conclusion he describes the innervation of the heart and remarks how many points are yet undecided in the physiology, and pathology is still further behind.

25. **Spermine Crystals in Pus.**—Williams reports the results of examination of pus from a case of long continued cervical abscess in which he has found spermine crystals in almost every slide. He also found great numbers of needle-shaped crystals, which, he concludes, must be adenine, guanine or sarcine, with others which he took for xanthine. If his observation is not at fault this finding of spermine in the pus makes the fourth or fifth of the nuclein bases thus far observed and xanthine may also be added as a possible discovery by himself.

28. **Blood Structure Study.**—Birchmore reports observations on the blood of a turkey which had been killed by cutting the carotid artery by way of the mouth. The knife thrust had opened the way into the lymph space and the blood had filled it, and, coagulating superficially, had half-sealed the wound of entry. The head and neck were dissected not less than 120 hours after killing and the findings strongly suggested embryologic conditions of the blood; he thinks that certain developmental changes take place in the body after death. The animal was over-stuffed with food. The blood was peculiarly in a condition to feed the corpuscles, which might be regarded as the only living cells left in the body. The absence of air reproduced to a certain extent embryologic condition, though the absence of heat was different. He asks does this combination of ample food with deficient respiration and heat explain the pertinacious following in the steps of development impressed upon the substance of the cells, the exceeding slowness of metabolic change, the persistence of these shadows, the simulacra of embryonic conditions. If so, he says, one is tempted to ask what would have happened between the condition reached and the moment when the pseudo-embryonic tissue, its growth-impulse exhausted, or no longer protected by environment, was assailed by the agents of decomposition. The question he leaves unanswered.

31. **The Prophylaxis of Tuberculosis.**—Before advising prophylactic measures the question of their practicability is raised by Kueber. He remarks that the laws proposed by certain boards of health are of doubtful utility. The danger of infection is not founded upon indisputable facts. Since 1854 there have been in Gerbersdorf, according to Brehmer, more than 10,000 consumptives and he asks, what quantities of sputum have not been ejected on public highways and streets and what quantities of infected matter have not been breathed by the inhabitants of Gerbersdorf, among whom the percentage of consumptives has decreased during the last twenty years from 0.41 to 0.18 per annum. Pollock says as regards infection that he has investigated the Brompton Hospital from the beginning until now and there has been among the nurses, house physicians, dispensers, floor scrubbers, etc., no more than four cases in fifty years. Out of 4000 cases which he has attended in hospital practice, at least 30 per cent. had the hereditary element. Other facts mentioned are the decrease in consumption in the British barracks since the ventilation has been improved and among the monkeys in the zoologic gardens in Paris. If there were one-half as much danger from infection as some would have us believe, it would be very unwise to send patients suspected of consumption to places full of consumptives. More than one hundred years ago the most stringent measures against the spreading of consumption by infection were enforced in Naples for several years. The result was a great hardship on the population without the least decrease of the mortality from consumption. Anyone who gives attention to the cause must conclude that the danger of infection is of subordinate importance, and, if the boards of health instead of wasting their efforts in impracticable measures would concentrate their efforts on regulations of indisputable merit, a great deal of good could be accomplished. A change for the better may be looked for when the boards of health and public have become convinced of the following: 1. That the tubercle bacillus is ubiquitous and that we can not escape it anywhere. 2. That the bacillus is harmless until it finds a congenial soil. The same is true also of some other bacteria. It was shown at von Leider's clinic in Berlin, some time ago, that ordinary bacteria in the blood circulation of animals affect the heart valves only when these are already injured. 3. That the human body offers a congenial soil when its vitality is undermined by one or the other of the many causes that are deleterious to health. 4. That there is no better and surer and easier preventive against consumption than to keep the body proof against tubercle bacillus. This can be done by avoiding the causes that make the human body susceptible to it. Foremost of these and the one most disregarded is working, living and sleeping in a confined and contaminated air. Few people give attention to the ventilation of their sleeping rooms. Sunshine and air are the last things thought of. The next noteworthy causes that undermine the vitality are certain occupations, such as stone cutting, needle grinding and workers in dust, and instances of prolonged worry, dissipation and irrational feeding.

32. **The Home Management of Epilepsy.**—The treatment of epilepsy is discussed by Porter, who shows the bad effects of even careless words, harsh fault-finding and especially of unfavorable environments. No fixed rules or regulations, however, can be laid down. Each individual must have his own treatment. A few of the patients, especially among children, may show some minor defects in manners; it is best as far as possible to ignore many of their shortcomings. The proper training of the mind, abstinence from stimulants, prudence and temperance in diet and mental diversion are especially advisable. Fear, anxiety and worry are dangerous conditions of the mind, and discussion of the condition or any remarks in regard to the probabilities of the case in presence of the patient are to be condemned.

33. **Retroversioflexio-Uteri.**—In this article Bandler describes the anatomy and physiology of the condition, and the following is a summary of his views, leaving out the question of retroflexio-fixata, and the peritoneal complications of retrodeviations: 1. Retroversioflexio per se is not a pathologic condition. 2. The majority of retrodeviations are of congenital origin. Retroflexioversio is not an obstacle to the cure of pelvic affections. 3. Where retroversioflexio without peritoneal, tubal, or ovarian complications causes symptoms, an hysteroptosis must be taken into consideration, always bearing in mind the possibility of other physical states, especially gastroptosis, enteroptosis, ren mobilis. 4. Prolapsus vaginæ and cystocele, while often associated with retrodeviations, are independent affections. 5. Where retroversioflexio is accompanied by severe local symptoms, these, if not due to peritoneal, tubal, or ovarian complications, may be corrected in the vast majority of cases without surgical treatment.

35. **Progress of Gynecology.**—Dorsett reviews the progress of gynecology and obstetrics, calling attention principally to the surgery and the advance in the matter of perineal operations and in the surgical treatment of fibroids. Since he has

used the angiotribe in the latter, he considers the operation less dangerous than before, as ligatures are dispensed with, the vessel is just as safely disposed of and the time shortened. He says the more one studies the question of the management of fibroids the more convinced he becomes that in the great majority of cases myomectomy should only be performed in cases where the tumor has a pedicle. The ragged bed left after the enucleation, composed as it is of bruised and devitalized tissue, is too fertile a soil for the propagation of pathogenic organisms. He also mentions the importance of early diagnosis of a malignant disease and the abuse of the curette. As regards the advisability of Cesarean section in placenta previa, he says it is difficult to approve of this method, though one feels that it may be possibly justifiable in this most dangerous condition, if in any.

38.—Ibid., p. 1727.

49.—This article has appeared elsewhere. See The Journal of September 28, title 155, p. 863.

50. **Uterine Irrigation.**—Fitzgerald advises the use of free intra-uterine irrigations in cases of infection in preference to the curette. He has been making use of the irrigation in all septic and toxic-genetic troubles, but especially in puerperal conditions where he thinks its benefit has been most apparent. He advises irrigation well up to the fundus, flushing of the uterine cavity with carbolized water by reflux irrigator with a fall of two feet, and, while it is still in the uterus, the douche is detached and, by means of a short tube, a small glass funnel is attached which should be held about fourteen inches above the end of the irrigator and a little peroxid of hydrogen introduced at a time, giving time for action of each addition. He would repeat this operation after several hours and has found this method very satisfactory in cases of uterine infection. The curette should be used less frequently and more reliance placed upon the stimulating, unirritating, intrauterine douche and free drainage, preceded always by thorough removal of all infected matter that can be taken away without injury to the normal structure, with subsequent irrigation, repeated as indicated.

52.—This article has appeared elsewhere. See The Journal of August 24, p. 495.

57. **Chronic Nasopharyngeal Bursitis.**—The bursa pharyngea which occurs in the vault of the pharynx exactly in the median line is not a congenital one, but may occasionally be traced to arrested development. Its existence is doubted by some writers, but Roy has been able to find it almost universally present in this opening in the vault in cases where there are decided objective symptoms of nasopharyngeal catarrh. He reports cases and thinks there must be something more present besides adenoid hypertrophy to account for the condition. The reason why it is not more often recognized is largely due to the fact that it is not frequent and probably not recognized as a distinct condition by many observers. While he believes in it himself he can not agree with Thornwaldt in attributing every case of postnasal catarrh to this condition. The best treatment he has found, in addition to thorough cleansing which the patient can do at home, is the application of a solution of silver nitrate, 60 gr. to the ounce, directly to the sulcus, followed by thorough spraying of the nasopharynx with hot melted vaselin and orthoform. His success with the curette and electro-cautery was not encouraging.

58. **Injuries to the Uvula.**—Oppenheimer reviews the various traumatic injuries to which the uvula is subject, all results of direct violence, excepting those due to extensive strain of the parts sometimes observed in singers, or from violent force to clear the throat as is hawking. In these cases the symptoms are altogether out of proportion to the apparent amount of injury. No special form of treatment is indicated, excepting when the tissues have been lacerated, then the local application of ice is very useful. In extensive edema, multiple incision is indicated, and in any inflammatory condition mild soothing applications are valuable.

59. **Apposition of Simple Incisors.**—The condition when the two middle front teeth are separated by a space is due, according to Loeb, to a small ridge of tissue which passes from the labial frenum downward between the teeth and depends upon the implantation of the frenum upon the gingival surface. When the attachment is high up the fibers are lost before they reach the inner surface of the alveolus, while, when it is low down, the fibers in the vast majority of cases continue between the two central incisors and are spread out in a fan-shaped manner between the palate. These observations were made on the living subject and while the condition has no bad effects, from the cosmetic standpoint it is undesirable. The operation which he advises consists in plunging the galvanic knife in the median line, beginning at the upper and anterior margin or mass of tissue just described and carrying it well into and behind the alveolus even to the fan-shaped prolongation on the palate. One application will sometimes be sufficient, though three or four may often be necessary. The operation may be performed before the retention bands have been applied or during their application and use. Care should be taken not to insert the cautery point too close to the teeth; the reaction from the operation is very slight, not more than from cauterization of the nose.

62. **Acute Lacunar Tonsillitis.**—This condition occurs most frequently between early life and adolescence. It is undoubtedly infectious and to a moderate degree contagious. The cervical lymph and ear complications need only to be mentioned. The treatment is local and constitutional. Ward does not claim to be able to abort the condition. All we can hope to do by local treatment is to modify the severity, as it is self-limited. However, indiscriminate local treatment, digging and probing is productive of more harm than good. He has been in the habit of giving the following as a routine treatment:

℞. Acid. carbolic ....gtt. x
Acid. boracic
Sod. biborate āā ....ʒiss
Hydrogen dioxid
Borolyptol, āā ....℥i
Aquæ dest. .... q. s. ad f. ℥viii

He advises also small particles of cracked ice or water and spray in the early stages of the disease. If there is any indication of extensive lymphatic involvement, the ice-coil may be used. The constitutional treatment consists in free purgation with calomel and effervescent sodium phosphate. For fever, headache, and muscular pain he usually combines codein sulphate, salol and phenacetin, in proportion to suit the age and requirements. With a previous history of rheumatism he relies on salicylate of strontium or soda, and tincture of chlorid of iron is a remedy, the value of which can not be overestimated. It has a decidedly beneficial local effect and a selective action on the blood and kidneys, and should be given during the acute stage and continued into convalescence. One attack predisposes to another and the removal of the troublesome organs should be practiced during the quiescent periods, but never in the active stage of the disease.

63. **Non-Syphilitic Mucous Patches.**—The conditions which simulate syphilitic mucous patches are as follows: Aphthous stomatitis, which is usual in children, is inflammatory and has a thick yellowish exudate; herpes buccalis, also painful and otherwise different, and pemphigus, which is more serious and in which anti-syphilitic treatment would be decidedly harmful. Close observation will reveal the remains of an elevated cuticle and in some the lesions are apparently preserved. Leucoplakia, however, is the most frequent cause of error. It is more permanent in its character, the surface is smooth, tough and warty. It is aggravated rather than benefited by anti-syphilitic treatment. The use of nitrate of silver or chlorate of potash may also give trouble, which may cause confusion. Joachim believes what are apparently very much like syphilitic lesions do sometimes appear on non-syphilitic subjects and that the evidence is not always safe for diagnosis and treatment of syphilis.

77.—See abstract in THE JOURNAL, xxxv, p. 1107.

81.—This article appeared in THE JOURNAL of July 6, p. 20.

84. **Mercury.**—The much discussed physiologic action of mercury in the system is again reviewed by Porter, who sums up the principal action of the mercurials as follows: "1. Stimulant to the hepatic cells. 2. Cholagogue in action by virtue of exciting hyper-secretions of the bile acids. 3. Sedative due to the two previous actions. 4. That its alterative, antiphlogistic, anti-syphilitic, diuretic actions, etc., are secondary to the above actions. 5. That ptyalism from mercury is due to the inactivity of the hepatic cells, and to the salivary glands attempting to do what should have been done by the hepatic cells."

85. **Onomatology.**—Rose criticises the incorrect Greek of medical nomenclature, calling attention to such words as appendicitis, conjunctivitis, albuminometer, etc., and such incorrect ones as chlorosis, polyclinic, glycosuria, hemophilia, etc. He admits that the question of introducing correct Greek terms in place of the incorrect ones is a rather serious one, but suggests a committee of competent physicians and philologists combined be appointed by some representative medical society.

95. **Neurasthenia.**—Brown coins a word "neurenergen" which he defines as a supposed ultimate form of organic matter contained in the neurons, through which agency it is convertible into waste products and various manifestations of nervous energy. According to this conception, there is in health a current of neurenergen constantly flowing into the neurons, which is no less constantly transformed by them into energy and waste products. This notion is specially applied to neurasthenia in which condition there is a standing deficiency in neurenergen. The causes of neurasthenia are noticed, including age, shock, worry, etc. He recognizes a class of people who are in a state of congenital chronic lack of stamina which he would not include under this head. Motor neurasthenia is best illustrated by the stale athlete; the sensory form has no special diagnostic symptoms. The mental form is characterized by lack of capacity of attention and mental confusion. Involvement of the special senses and the vegetative organs are also mentioned. The rest cure he thinks is somewhat overdone, too many promoters are taking hold of it and administer it without regard to medical advice. Still it is an excellent method under proper supervision, though men will seldom submit to it. Much outdoor life should be required in most cases, regulated exercises, a generous diet, and regular and frequent periods of rest. The neurasthenic business man should shorten his hours, a proper sort of vacation occasionally affords relief. The tact and skill of the physician are particularly taxed in these cases. He never receives compensation at all commensurate with the value of his services.

96. **Pneumonia.**—The utility of venesection followed by saline infusion is argued by Porter, who does not, however, advocate the method to the exclusion of others. The rationale of the treatment is discussed by him and he says he believes the whole treatment of lobar pneumonia may be summed up in a brief formula: conserve the strength, guard the heart and diminish the toxins. It is a self-limiting disease, but should be helped over the severer places. The mortality is at present greater than it should be, and the early routine and reckless use of heart depressants are responsible for disasters at later stages. He reports a case in which he considers venesection and saline solutions saved the patient, where ordinary remedies would have failed.

105. **Mental Therapeutics.**—Bridge believes that we should lessen the emotional attention to infants, which may produce even true neurasthenia in the first year, and not try to be constantly entertaining children or encouraging emotions that may be vicious ones; later in life we should stop trying to make them young ladies and gentlemen. We should lessen, as far as possible, the emotional strain at school, the fear of failure, etc. Some children suffer this way; increase of outdoor life would be better for people in general. Too much indoor life keeps us below par. The desire to shine in society and business is more often the cause of neurasthenia than nervous overwork. We must have less dress parade in our lives. People who are carrying mind and body loads which are too heavy should have them lessened.

106. **Spider Bites.**—The danger from poisonous spider bites is a popular belief. According to Browning there are but two species of spiders in Southern California reputed to be poisonous; one, of the genus "Phidippus," which is hairy, with red spots on the upper surface of the abdomen, belonging to the family of wandering spiders, seeking its prey after the manner of the feline race; the other, of the genus "Lactrodectus," glossy black, with red spots on the under surface of the abdomen and belonging to the family of line-weavers. He does not know of any case where the bite was specifically stated to be due to the former species, though the conditions of the accident and the lack of characteristic symptoms of the other type lead to suspicion in some cases; a number of cases have been reported of the lactrodectus bite, the results of which may be very severe and even fatal in some cases. The animals seem to prefer outhouses and most bites have been received in them. It is not specially aggressive, but probably is dangerous because of its locality, in the seats of outdoor closets, etc. These seats, he thinks, should always be made to swing on hinges to protect against this. The general symptoms are more often severe than the local ones and may take periodical form, occurring at regularly certain periods of the day. General prostration and weakness is occasionally observed, the first symptoms occurring a few minutes after the bite, with severe rigor, nausea, depression of heart action, lowered temperature, cold perspiration, severe pain in the lumbar region, gradually extending towards both the extremities and the precordia and followed sometimes by convulsions and death. Generally, however, the circulatory and respiratory symptoms begin to ameliorate, temperature and pulse becomes normal, but the pain continues however, and also a slight general edema. He reports a fatal case.

112. **Malaria.**—Burns suggests an antagonism between malaria and typhoid infection, giving his experience as proof of this view. In the region from which he writes the conditions of soil, sewage and water supply are just such as would appear conducive to the propagation of the typhoid germ. This, with the advantage of an insalubrious climate, with people generally below par, yet does not produce many cases of typhoid. He does not believe in any form of malaria that is not amenable to quinin. Hemorrhagic malaria is mentioned. He has had a number of cases where there was spitting of blood and other signs of pneumonia without pneumococcic infection, while blood smears have shown the plasmodia. All cases responded in three or four days to a good gland arousement and quinin. Some of these cases he has regarded as prebacillary tuberculosis. Blackwater fever occurs in his region, and, contrary to what Dock says, the condition is not hematuric. It is in all essential particulars the same as, and in fact is, a malignant malaria with a condition of hemoglobinuria and rapidly increasing jaundice. It usually occurs in old residents, rarely in newcomers and more often in males than females. He does not believe in toxic hemoglobinuria other than from quinin, and he does not hesitate to use quinin in this condition.

122. **Apomorphia.**—Pugh recommends the use of apomorphia in cases of asphyxia to stir up respiration, and would give it hypodermically in the arm or over the stomach in .10 gr. doses every ten minutes. He reports a case where he aroused a man in this way who had been reported dead by two physicians after suffocation from coal gas. He would also use it in drowning and lightning stroke and opium poisoning, though its effect as an emetic if given early would be self-evident in this last case. We have in it also one of the valuable remedies in retarded labor, due to rigid os, and in cases of strangulated hernia, where it produces relaxation; this alone with gravitation often relieves the condition. He says he has treated a number of strangulated cases in this way and always with success.

British Medical Journal, September 21.

A Simple and Rapid Method of Producing Romanowsky Staining in Malarial and Other Blood Films. W. B. Leishman.—The author describes a simplified method of producing the Romanowsky staining of blood films with a solution prepared as formerly described by him in a previous note. Solution A: Medicinal methylene blue (Grübler). A 1 per cent. solution of this was made in distilled water, and then rendered alkaline by the addition of .5 per cent. of sodium carbonate, then heated to 65 C. in a paraffin oven for twelve hours, and afterwards allowed to stand at room temperature for ten days before using. Solution B: Eosin, extra B. A. (Grübler), 1 to 1000 solution in distilled water. Equal volumes of these two solutions, A. and B., were then mixed in a large open vessel and allowed to stand for from six to twelve hours, stirring from time to time with a glass rod. The abundant flocculent precipitate resulting is then collected in a filter, thoroughly washed with distilled water until the washings are colorless or have only a pale blue tinge, and the insoluble residue carefully collected, dried and powdered. The resulting powder, which has a greenish, metallic luster, constitutes, or at least contains the active staining ingredient in Romanowsky's method. Full directions for the manufacture of this dye has been furnished to the firm of G. Grübler & Co., Leipsig. The best solvent for this dye which he has found is pure methyl alcohol, and, by taking advantage of the powerful fixative properties of this alcohol, Leishman is able to dispense with any separate process of film fixation. The dye prepared as the above should be dissolved in methyl alcohol in the proportion of 0.15 per cent., and the resulting solution kept in stoppered glass bottles until required for use; it does not deteriorate by keeping. It is of a clear dark-blue color, and shows a greenish iridescence when illuminated by reflected light. It is applied directly to a film on a cover glass and no attempt made to check the evaporation. After about half a minute, double the quantity of distilled water, that is 6 or 8 drops, are added and allowed to mix with the alcohol solution of the dye. Intimate mixture is hastened by rotating the forceps, and the films are allowed to stand for five minutes, though ten minutes may be necessary with thick blood films or smears from cellular structures. The stain is gently washed off with distilled water and a few drops of water allowed to rest on the film for a minute. At the end of this time the specimen is ready for examination, either directly in water under a one-sixth or one-eighth inch objective, or, after drying (without heat) and mounting in xylol balsam, under an oil-immersion lens. The whole operation, from the withdrawal of the blood to the mounting of the stained film, can be done within seven or eight minutes and no reagent is needed beyond a few drops of the stain and a little distilled water. Where the latter is unobtainable, rain water or soft hydrant water may be used without greatly affecting the results. The soaking in distilled water for a minute after the staining is important as intensifying the Romanowsky stain; it removes the remains of the deposits and changes the tint of the red blood corpuscle from a greenish blue to a transparent pink, or greenish, and nuclei of the leucocytes usually a ruby-red. The nucleated red cell is stained almost black with sharp outlines, and the extranuclear portion, gray. The blood plates are deep ruby-red with spiky margins, frequently showing a pale blue peripheral zone surrounding the red center. The bacilli and micrococci generally stain evenly blue, but, by prolonging the period of staining and decolorizing with absolute alcohol, many interesting differences may be noted in the different organisms, bringing out the structural details not generally observed with other methods. The body of the malaria parasite stains blue, and its chromatin, ruby-red. In the case of the tertian parasites Schueffner's dots are well marked in the containing red corpuscles.

The Value of Neisser's Stain in the Diagnosis of Diphtheria. R. M. Beaton, F. Foord Caiger and Walter C. C. Pakes.—The authors have studied the comparative values of the Neisser's stain and the methylene blue stain and find from their investigations that the former is a valuable one in several ways: "1. A positive diagnosis is rendered more certain for those who can not be considered as experts, since it is often easier to diagnose the Klebs-Loeffler bacillus after staining by Neisser than after staining by ordinary methylene blue, as we think that for the inexperienced the bacilli after staining by Neisser's method are much more characteristic than after staining by methylene blue. 2. A trustworthy positive result may be obtained from the microscopic examination of a preparation made direct from the swab, and this method is, we think, not only more reliable when Neisser's stain is used, than when the ordinary methylene blue is employed alone, but is more obvious. 3. The use of Neisser's stain does not appear to introduce any fallacy not found in the application of other methods."

Pneumococcus Peritonitis.—Three cases of pneumococcus peritonitis are reported and the condition discussed. Bryant finds that it rarely occurs in adults and when it does, men are more liable to be affected than women. In children, on the contrary, girls are much more frequently attacked. Why the peritoneum should be attacked by the pneumococcus is not clear. The source of infection may be by the alimentary canal. The fact that pneumococci are frequently found in the mouths of healthy people would indicate that they can be easily introduced into the digestive tract. The possible explanation as to the reason that the peritoneum is so rarely affected by this organism are that the ordinary digestive fluids are inimical to its growth and development. If, however, there is a severe gastro-intestinal disturbance of any sort there will be not only a general lowering of bodily resistance and lowered local resistance, but also an altered condition of the secretions. This may predispose to the growth and development of the germ and allow its passage by means of the blood vessels and lymphatics to the peritoneum itself. The large proportion of girls to boys would indicate that there is the possibility of infection taking place through the Fallopian tubes or uterine blood vessels, but the rarity in adults would not agree with this. He is inclined to think from the chemical and pathologic evidences that the primary infection of the peritoneum is probably through the alimentary canal, with a subsequent general blood infection leading to pleural infection. When the peritoneum is infected through the lymphatics, it is nearly always secondary to pneumonia or pleurisy, and the part of the peritoneum most involved is that covering the upper part of the liver and spleen. In some of the cases of local pneumococcus peritonitis the organism may be conveyed from the uterine cavity to the peritoneum by the lymphatics and not by the Fallopian tubes, and he thinks that when the infection is carried in this way the peritonitis is much more likely to be local than general. The skin is another possible channel by means of which the pneumococcus can reach the peritoneum, but thus far he has seen no cases that point to this manner of infection.

The Pathogeny of Exophthalmic Goiter. E. Gley.—The theory of the pathogeny of exophthalmic goiter is discussed by Gley, who says the old idea of its being a cardiac condition or a pure neurosis is generally abandoned. The hyper-thyroidization theory, however, is still held to some extent, but he points out the difficulties, and the fact that thyroid alimentation may even benefit this condition in some cases, is a difficult one to explain by it. The idea of sympathetic excitation has also its difficulties. The phenomenon in its turn needs an explanation; what causes this excitation of the sympathetic is not stated by those who hold this view. The theory of the part played by the parathyroid bodies in this condition is to be considered, and he goes to some length into the physiology of these organs, maintaining that they are functionally associated with the thyroid and that the proteo-iodid substance is not produced in the thyroid without the assistance of the parathyroids. If the latter are altered its production is diminished, hence we come to the theory that exophthalmic goiter is due to alteration in the thyroid apparatus involving in the first place functional disturbance of the parathyroid bodies. He refers to the researches of Oliver, Schaefer, and Haskovec showing that the extract of the thyroid produces a stimulative action on the sympathetic and a depressant antitoxic action on the heart. In exophthalmic goiter Haskovee concludes that the thyroid gland is diseased and the mechanism by which the symptoms are produced is by entrance into the organism of toxic substances, having a selective action on the sympathetic system. Gley asks, may we believe that the toxic substances result from lowered functional activity of the parathyroid glandules because of the inability of the secondarily diseased thyroid to neutralize them? The question, however, can not be definitely answered.

On the Urine in Tuberculous Infection. ALEX. G. FOULERTON AND WILLIAM T. HILLIER.—The authors have investigated the urine in cases of tuberculous infection by chemical and microscopic examination, and by animal inoculation experiments have tested also for albuminuria, urea, diazo reaction, etc. They summarize their inoculation experiments as follows: Of 18 patients suffering from more or less chronic, tubercular, pulmonary phthisis, the urine contained bacillus tuberculosis in 9; in 6 of these, the absence of tuberculosis of the urinary tract was proven by postmortem examinations and there was no reason to suspect that the condition existed in any of the other 3. So far, therefore, as they can generalize from a series of only 18 cases it can be said that the urine of 50 per cent. of the far advanced cases of tuberculous pulmonary phthisis, contained bacillus tuberculosis, virulent to guinea pigs. In only 1 of these 7 cases examined postmortem was there any evidence of infection of the kidney. While the facts show that general blood infection as evidenced by the presence of the bacillus in the urine is more common in cases of consumption than generally supposed, it also shows that when it invades the blood, it does so usually in extremely small numbers and has but little tendency to multiply there, and that any occasional bacilli that may get into the blood stream are eliminated by the kidneys. These glands show only a slight tendency to become infected in the process. They suggest that it is probable that the patient in many cases of phthisis is undergrowing a gradual process of auto-immunization and that after a time the tissues generally are less susceptible to infection than when the pulmonary infection occurred. Only in this way can we explain the fact that, considering the frequency with which the germs get access to the blood, dissemination of the tuberculosis is comparatively uncommon in chronic, tuberculous, pulmonary phthisis. They do not apparently find much to indicate the value of guinea-pig inoculation in the diagnosis of tuberculosis. In a number of cases 2 c.c. of urine were injected into healthy animals, and careful observations made to ascertain whether such urine showed any difference as regards the immediate toxicity from the urine of healthy individuals, but none was detected.

Bacteriology of Cerebrospinal Meningitis. A. W. NUTHALL AND W. HUNTER.—The following are the authors' conclusions from their studies of the literature and examinations in cases of disease: "1. In 10 cases of meningitis a diplococcus was isolated from the cerebrospinal fluid obtained by a lumbar puncture during life. 2. This diplococcus agreed in its morphologic and biologic characteristics with the diplococcus intracellularis meningitidis of Weichselbaum. 3. The diplococcus occurred in two slightly different forms—types A. and B. 4. In some cases the diplococcus was present in pure culture, in others associated with micro-organisms—for example, bacillus influenzæ and bacillus tuberculosis. 5. The clinical picture and pathologic changes found in these cases were those met with in posterior basal meningitis. 6. In all probability posterior basal meningitis is a sporadic form of cerebrospinal meningitis and is caused by the same micro-organisms—the diplococcus intracellularis meningitidis of Weichselbaum. 7. In the majority of the cases it was impossible, from the clinical aspect alone, to make a correct diagnosis of the variety of meningitis present."

Contribution to the Histo-Pathology of Yaws. J. M. H. MACLEOD.—The following is a summary of the histologic changes which MacLeod finds suggesting that yaws and syphilis are different histologic entities: "1. Cellular infiltration.—The plasma cells are not so definitely clustered around the vessels in yaws as they are in syphilis, nor do they ever form foci suggesting a tuberculous nodule, as they occasionally do in the latter disease. They are seldom arranged in rows which frequently occurs in syphilis. Large multinuclear cells (chorioplaques) and true giant cells, which may be present in syphilis, are absent. No hyaline degeneration, such as may be found in syphilis, is detected in the plasma cells. 2. Fibrous stroma.—The rarefaction of the collagen is more marked in yaws than in syphilis; organization is not detected, and the colloidal degeneration, such as occurs in a syphilitic gumma, is absent. 3. Blood vessels.—There is no tendency to thickening of the vessel wall or to endothelial proliferation, such as so frequently pertains in syphilis. 4. Epithelium.—The proliferative changes in the epidermis in yaws are only equalled in syphilis in the condylomata, while the marked tendency of the stratum corneum (hyperkeratosis), which is an invariable characteristic in yaws, is unusual in syphilis."

The Lancet, September 21.

The Occurrence of Green or Blue Urine and Its Most Frequent Cause. F. PARKES WEBER.—Weber considers that a blue urine, occurring without obvious cause, is generally due to undue eating of sweets colored with methylene blue. The digestive disturbances which sometimes accompany the symptoms are probably due to over-eating of sweets, as they are not produced by much larger quantities of the coloring agent taken by itself. He is skeptical as to the power of other substances to produce the symptom excepting in very rare cases.

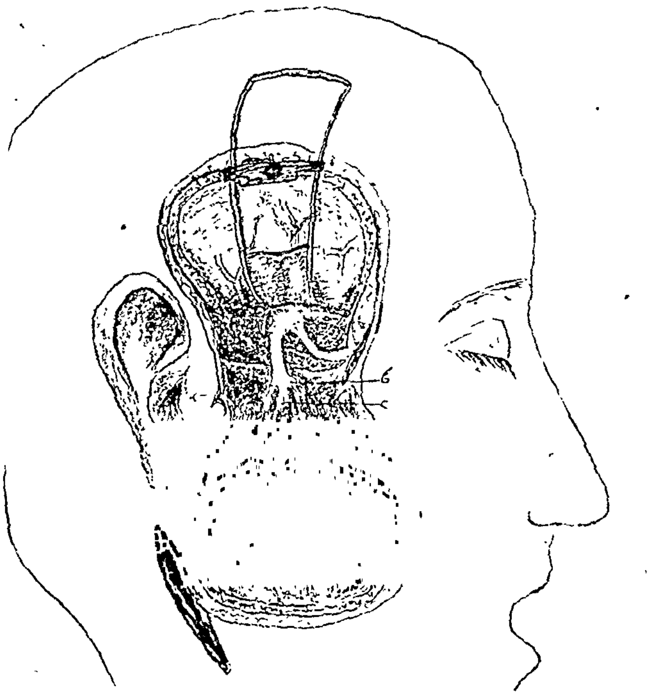
Three Points in Practical Midwifery. G. W. ORD.—The three points in practical midwifery mentioned by Ord are as follows: 1. That the catheter is capable of saving life in the course of breech delivery. He had a case where the body was born and cord pulsating; the head, however, stopped and the cord ceased pulsating, and it seemed that the child would be born asphyxiated. He had a catheter in his bag, a silver, male instrument, and feeling his way he passed it into the child's mouth, who cried down the catheter, the chest became inflated and in a few minutes the head was born, and everything was satisfactory. In looking up the literature he found the plan suggested but not specially recommended in Playfair's work, but the case has been a surprise to every medical man to whom he has mentioned it. The catheter did its work perfectly and in such cases where the necessity of delay of three or four minutes occurs in the birth of the head, the value of this method is obvious. 2. Another point to which he calls attention is the matter of hour-glass contraction. He has in his experience found this frequently after experimental delivery and for the last six or eight years he has pursued the method of "expressing" the child after the birth of the head and has had no hour-glass cases when he has been present before the birth of the child. It seems to him that the cause of hour-glass contraction is due to quick delivery by traction of the child and is avoidable if the *vis a tergo* method only is employed. 3. This is that scoliosis is possibly caused by traction on the infant's body during birth, and that we should realize the damage we may be doing to the spine when pulling in the various directions, as we are advised in text-books. Besides the possible scoliosis another danger may occur, the suprarenal capsules may be injured. He quotes from Clifford Allbutt, who says that hemorrhages in these bodies frequently occur as results of traumatism during birth. Such hemorrhages occur more often in difficult labors and are more frequently met with in pelvic and cephalic presentations. He believes in the soundness of the use of the catheter with an after-coming head, if any hitch occurs, as opposed to traction.

Presse Medicale (Paris), September 14.

Tuberculous Rheumatism. MAILLAND.—Poncet called attention, in 1890, to the infectious pseudo-rheumatism which may accompany tuberculosis at any stage and in any of its forms. It had hitherto been considered true rheumatism, but the inefficacy of sodium salicylate, the character of the pains and the final localization on a single joint, differentiate it from chronic arthritis deformans or acute polyarticular rheumatism, although the clinical manifestations at first are strikingly similar. The termination is different, as the lesions are not fungous, suppurating, nor destructive as in ordinary white swelling, but are merely lesions of irritation, with a fibro-plastic tendency, like the pseudo-rheumatism of infectious diseases, and may range from simple arthralgia to complete ankylosis. Mailland describes a few typical cases, including one of a tibio-tarsal osteo-arthritis presenting the clinical signs of osteo-tuberculosis. It had been preceded two months before by manifestations of articular rheumatism, localized in both shoulders. Signs of tuberculosis were found in both apices. In another case, the knee and both ankles had been affected with supposed acute articular rheumatism at intervals during fifteen years. Finally the pain in the knee became chronic and the affection was recognized as a tuberculous arthritis, soon followed by death in tuberculous cachexia. Characteristic tubercular granulations were found in the pleuræ at the autopsy. In a third case, supposed rheumatism of the shoulder, wrist and knee finally localized exclusively in the knee, which became completely ankylosed. Death from pulmonary tuberculosis occurred in eight months. Tuberculous rheumatism is probably due to the action of the toxins generated by the bacteria. The pain in these infectious pseudo-rheumatisms is usually most intense in the center of the articulation. In true rheumatism, the surrounding parts are most sensitive. Lasegue even claims that there is no intra-articular pain in acute articular rheumatism, and that the joint can be worked without much pain, if the surrounding parts are spared, while in infectious pseudo-rheumatism, this is impossible, as the pain is in the very depths of the joint. When in presence of a case of pseudo-rheumatism, with no gonorrheal nor puerperal antecedents nor any infectious disease capable of inducing such disorders in the joints, the possibility of tuberculosis must be borne in mind. The tuberculous pseudo-rheumatism may be the first clinical symptom of incipient tuberculosis. The treatment is the same as that of any established tuberculosis.

Revue de Chirurgie (Paris), September.

Resection of the Gasserian Ganglion. K. Sapejko.—In most cases of neuralgia involving the fifth nerve, when the pains are limited to one or two branches, and when the effect of peripheral section of the nerve persists for at least six months, the neuralgia is evidently of peripheral origin. But when the pains are located in all three branches, even alternately, the neuralgia must be due to an intracranial affection of the trifacial system. If the pain is confined strictly to one side of the face, the Gasserian ganglion or possibly the root of the nerve, is probably the seat of the trouble. If the pains pass from one side of the face to the other, the central nuclei of the trifacial nerve are probably involved. The majority of cases of peripheral neuralgia can be cured by resection of the nerves affected, but when a rebellious neuralgia invades all three branches—thus demonstrating its central origin—the Gasserian ganglion should be resected without causing delay by preliminary operations. The most plausible supposition in this case ascribes the seat of the lesion to the ganglion. In the cases also, in which the neuralgia has persisted after resection of the peripheral nerve, the removal of the ganglion offers a last resort, to destroy the nerve and render regeneration of the peripheral nerves impossible. Instances have been known of recurrence of this neuralgia even after resection of the Gasserian ganglion, and Sapejko reports a case of this kind in detail. He attributes recurrence to the immense anatomical and technical difficulties of the operation. Some fiber must have been left which finally succeeded in closing the circuit, with recurrence of the pains in consequence. In his patient, sensation returned first at the periphery, followed by faint echoes of the previous neuralgic pains. The Quénu and Krause methods do not allow sufficient access to the field of operation, and there is always danger of injury to the brain as the assistant holds it out of the way during the long and tedious operation. Sapejko has simplified it by the following technique which is comparatively simple, practicable and allows ample and effective drainage of the wound. The flap is 4 cm. long, wider at the tip than the base, which extends the entire length of the zygomatic arch. The latter is sawed across and the great wing of the sphenoid is cut to include the round and oval foramina. This allows more ample access than the Krause and Quénu methods together. The brain is held out of the way by an automatic spring retractor which screws to the intact skull above, while the lower portion forms a metal mirror reflecting light on the ganglion. After isolating the ganglion, each of the three branches and the root must be pulled out and resected over as great an extent as possible. The ganglion is lifted out of its bed, and the root and first branch pulled out and torn as far from the ganglion as possible. The ganglion is then pushed to one side, and the capsule examined and scraped to remove every scrap of ganglion tissue, especially in the vicinity of the cavernous sinus, the root and the first branch. The second branch can be resected to its entrance into the infra-orbital canal. The third branch, with the ganglion still attached, is mobilized and pushed down and out through the small wound below, made for the purpose of provisional ligation of the external carotid, which is the first step in the operation. Its branches are loosened and pulled out as far from the periphery as possible before they are broken off. Connection with the otic ganglion is also destroyed. Drainage is accomplished through the route followed in extracting the third branch. The small incision over the carotid thus serves a triple purpose. If hemorrhage is excessive and interferes with the operation, after the patient is turned with his face to the operator so that the blood can flow out readily, Sapejko advises postponing the resection of the ganglion until two or three days later. In his personal case he operated strictly according to this technique, except that he did not resect the branches, and he attributes the recurrence of the pains to omission of this precaution. He covered the eye with a tight bandage and no inconveniences were observed at any time although there was complete anesthesia of the eye. He points out the necessity of differentiating neuritis from neuralgia, as the former requires treatment directed against the cause—constitutional, infectious, toxic or local inflammation, etc.—while neuralgia never yields to medicinal treatment except in case of mistaken diagnosis or hysteria. In neuralgia the cutaneous sensibility and the reflexes remain normal, while they are diminished in neuritis; the same applies to the strength of the muscles, and no spasmodic contractions are observed as in neuralgia. The pain is also constant and less acute in neuritis. Morphin is the only relief in neuralgia and surgical intervention the only means of cure, and even this may fail unless thoroughly complete. In Garré's case, the Gasserian ganglion was resected, and the maxillary



nerve was subjected to four resections, but after nine of these partial operations, the sensibility of the face was as acute six months later as at first. This case established the possibility of regeneration of the nerves after destruction of the ganglion, of return of sensibility after resection of the ganglion and all the various resections. He found that peripheral irritations were transmitted by the most minute anastomoses of the trifacial nerve through the otic and nasal ganglia, after destruction of the Gasserian ganglion, which is usually considered as the concentrating point of all the conductors.

Malignant Leiomyomata. Devic.—Myomata that develop in the unstriped muscles are usually benign, but a few cases have been published in which their malignant character was evident. They are probably more numerous, but have been classed as sarcomata. Devic describes a case in which a leiomyoma developed in the thoracic wall and recurred at the same point five times after as many operations in the course of the same number of years. When extirpated for the sixth time, the microscope showed the same structure, islands of adult fibro-cells, the tumor starting and extending in the arrectores pili. In a second case a leiomyoma in the outer surface of the thigh recurred three times in a year, and amputation failed to save the patient. In his third case a subcutaneous tumor had been noted for several years in the right external iliac fossa. It began suddenly to increase in size until it was as large as two fists. It was not adherent and not ulcerated. Six months later a tumor developed in the left flank, occupying the larger portion of the abdominal cavity, with ascites, and the liver much hypertrophied, irregular and knobby. At the autopsy six months later, multiple visceral generalization of malignant leiomyomata was found in the kidneys, liver, lungs, pancreas and thyroid body. The primary tumor was entirely subcutaneous, close to the gluteal aponeurosis, but not involving the latter. The secondary tumor in the kidneys weighed 8 kilograms. Six cases of malignant leiomyomata of the uterus or pelvis have been published in Europe, and two, of the stomach, all with visceral metastases. Devic was unable to find more than one case of a subcutaneous tumor of this kind, besides the three cases which he relates in detail. In this case a hard, indolent and movable tumor was noted in the postero—external wall of the right elbow for eight years. It suddenly began to increase in size and the arm was amputated. The cachexia continued and at the autopsy a year later, all the organs were invaded by secondary tumors. The primary tumor was diagnosed "a fasciculated sarcoma or spindle-celled fibroma, developed in the periostium of the lower portion of the humerus." The corrected diagnosis at the autopsy was that of malignant leiomyoma. The interlaced fibers are more regularly arranged in the tumors than in normal tissue or benign myomata, the cut surface is more iridescent. The fibro-cells are all adult and connective stroma is conspicuous by its absence, but giant fibers with nuclei 50 to 100 microns in diameter, are observed in some cases.

Deutsche Med. Wochenschrift (Leipsic), September 19.

Outlining the Organs by Transonance. M. Buch.—If a stethoscope with a very small funnel is applied for auscultatory percussion, it is possible to determine the outlines of nearly all the viscera with remarkable accuracy. The small funnel fits closer to the skin and locates the outlines much more exactly than the ordinary funnel. Buch applies it within the limits of the organ and carries the percussion to the boundary, which is readily recognized by the altered tone. He then transfers the funnel outside the organ and carries the percussion toward it, closing his eyes, so as not to be influenced by the mark he had placed at the outline first determined. After determining the outlines of the heart and lungs, those of the stomach can be located and also those of the other viscera, even of the spleen, colon, etc. The method is so delicate that the slight constriction, above and below, at the point where the fundus blends into the pyloric portion of the stomach is plainly evident. The percussion must be extremely light over the liver so as not to include the resonance of the stomach. Henschen was the first to call attention to this method of "transonance" as he called it. Runeberg does not tap, but rubs the skin lightly.

Muenchener Med. Wochenschrift, September 17.

Puerperal Fever. A. Hegar.—If the temperature does not rise beyond 101 F. after delivery, and if there are no local symptoms, Hegar restricts intervention to removing obstacles to the free flow of the discharge and irrigating the vagina. Temperature of 102 and over indicates drainage, if it persists more than twenty-four hours. Besides the temperature, accelerated pulse, rapid respiration, sleeplessness, tendency to cyanosis and local symptoms are accessory indications for drainage. Hegar thinks that washing out the uterus once or thrice a day is absolutely useless. For several decades he has made a practice of permanent drainage of the uterus, leaving the canula in place and repeating the irrigation every one or two hours. He prefers for the purpose a double glass canula with even the olive divided into two parts, allowing free inlet and outlet to the fluid. He maintains this irrigation and drainage for forty-eight hours, repeating it after suspension for twelve hours, if necessary. He considers chlorin water the best antiseptic for the purpose, and uses it in a 12 to 25 per cent. solution.

Remedy for Seasickness. R. Heinz.—The vomiting center and the respiration center are closely connected locally and functionally on the floor of the fourth ventricle. Heinz asserts that the desire to vomit can be deadened and abolished by taking deep respirations. He found in experiments on dogs that artificial respiration was able to prevent vomiting, even after the injection of apomorphin, which inevitably induces it in one to three minutes. Apnea reduces the excitability of the vomiting center and the desire to vomit subsides. He has found deep breathing effectual in warding off the vomiting of seasickness, both in himself and others.

Tamponing the Abdominal Cavity with Air to Arrest Threatening Intestinal Hemorrhage. G. Kelling.—In experiments on dogs, Kelling found that a negative pressure of 50 mm. mercury was perfectly tolerated, and that it was possible by this means to arrest serious intestinal hemorrhage. From examination of patients he believes that the pressure in the stomach vessels averages about 40 to 80 mm. Hg., and that this same method of air tamponing is clinically applicable.

Wiener Klin. Wochenschrift, September 19.

Operative Treatment of Double Stenosis of the Stomach. H. Schloffer.—Stenosis of the pylorus was associated with pronounced hour-glass stomach in the case described. The patient was a woman of 54 who had suffered from gastric disturbances for twenty-five years. Finally symptoms of stenosis developed, and Schloffer operated by making a longitudinal incision, 7 cm. long, in the constricted portion of the stomach between the fundus and pyloric region. He then stretched the walls of the stomach apart, until the incision was transformed into a transverse linear wound, which he sutured in this position, perpendicular to the longitudinal axis of the stomach. The organ was adherent to the posterior abdominal wall. He then made an anterior antecolic gastroenterostomy between the pyloric portion of the stomach and the upper jejunum, concluding with Braun's side-to-side anastomosis 20 cm. below, between the afferent and efferent loop. The patient was dismissed in sixteen days and is in far better health than for years previous to the operation. The only disturbance to date is a sensation of oppression in the stomach when she swallows food without sufficient mastication. The operation was performed at Woelfler's clinic, and the communication states that Braun's anastomosis is adopted there as a routine procedure to complete all gastro-enterostomies.

Myalgia Not Due to Getting Chilled; Its Prevention and Treatment. J. Elgart.—Ruhemann examined 7000 cases of affections of the respiratory organs and 8000 of so-called rheumatic affections, in order to determine the causal significance of becoming chilled. He became convinced that it is far from possessing the importance attributed to it, and that it has no effect except on the predisposed organism, that is, where bacteria are already present. In the absence of bacteria, getting chilled is unable to determine the most insignificant angina or rhinitis. Knövengal came to similar conclusions from a study of soldiers in barracks, but Chodounsky's recent experiments are still more conclusive. He inoculated 102 animals with cultures after previously chilling them, reducing the temperature by eighteen degrees, and found that the susceptibility to infection was not enhanced but rather diminished. Chilling the animals even as long as eight hours, failed to induce any affection except in a few instances of slight hyperemia of the lungs, which vanished without a trace in three days. He is a man over sixty years of age and not at all robust, but he experimented on himself, exposing himself naked to a current of air of 47 F., or after running till the sweat was pouring from his body, he rapidly undressed and stood in a draft of air at 37.5 F. only quitting in forty minutes because he was so cold. In other tests, after bathing the upper portion of the body with warm water, he exposed it to a current of air of 25 F. He also dipped his shirt in water at a temperature of 41 F. and putting it on at once, remained in a strong draft in damp weather, the thermometer at 39 F., and wore the shirt the remainder of the afternoon. He found that the temperature of the body rose two or three degrees during this chilling process. When the cold acts on a heated, reddened skin, the cutaneous vessels contract and the temperature rises above normal. He formally announces that currents of air under the most extreme conditions have no action on man. They do not induce catarrh of the respiratory organs, nor articular rheumatism nor neuralgia. He attributes the greater prevalence of these affections in winter to the lesser amount of sunshine with its bactericidal potency, and to the less hygienic manner of living, housed indoors. He also points out that we use cold packs, bath, etc., in combating infectious diseases, even in those in which we ascribe getting chilled as the primal cause. (Bohemian Clinical Archives, 1900.) Elgart accepts Ruhemann's view that the presence of bacteria is an indispensable preliminary to the origin of an affection from getting chilled. However, as bacteria can not be present in sound muscles, this explanation does not apply to myalgia or myopathy. He explains them as the result of injury of some muscular fiber which is atrophied from disuse or degenerated from age or from the action of some infectious disease. The muscle is abnormally fragile and the fiber may rupture from over-strain or in consequence of the contraction of the sound fibers, in which the degenerated fiber is unable to participate. The rupture is probably accompanied by some microscopic hemorrhage, with consequent compression of the nerve terminals and pain, the myalgia, and stiffness from the instinctive desire to immobilize the part. As the extravasation is resorbed, the pains disappear. Continuous stretching of sound muscles may induce myalgia as after unusual exertion in climbing, etc., but after the muscles have become habituated to the exertion, the myalgia disappears. Lumbago frequently befalls a person as he is stepping hastily into a carriage. The trunk is bent forward, the head down, and the lumbar muscles are submitted to a sudden strain, which may rupture some fiber. Besides this idiopathic myalgia, there is the symptomatic form, accompanying various infectious diseases. The "rheumatic stiff neck" which occurs so often with a febrile tonsillitis or rhinitis, is usually first noted as the subject is washing in the morning. In bathing his face and neck he twists his head around, and some muscular fiber is ruptured. If he awakes with the stiff neck, he has probably slept with the head in some strained position. These symptomatic myalgias are liable to occur in any infectious disease, and the latter may have been so trifling that the subject never noticed or has forgotten it, but the consequent slight degeneration of the muscular fiber is the cause of the rupture—not getting chilled. The more virulent the toxins in an infectious disease, the more intense the degeneration and the more fragile the muscle fibers. The prophylaxis of idiopathic myalgia consists in not allowing the muscles to become atrophied from disuse, by practicing gymnastics, sports, etc., avoiding overstrain as much as atrophy, combining and individualizing each case, with heed to the ordinary occupation, age, etc. In infectious disease, the prophylaxis is completely the reverse—here every effort must be made to avoid stretching the degenerated muscle fibers. Rest in bed protects the muscles from traumatic alterations, and during convalescence the muscles must be spared abrupt strains. Even during slight infections the muscles must be carefully guarded in the same way and gradually accustomed again to ordinary movements and exercises. Treatment of idiopathic myalgia includes diaphoretics, laxatives and massage, but the symptomatic form requires only rest. Elgart ridicules the fear of catching cold, which robs life of many of its joys and is an antiquated superstition. Appropriate nourishment and physical exercise are the true means of protection against myalgia, not precautions against getting chilled. The most warmly protected portion of the body is the lumbar region, and yet it is the chosen seat of myalgia, which is seldom if ever observed in the hands or face.

Queries and Minor Notes.

DISLOCATION OF HIP DURING LABOR.

RICHMOND, VT., Sept. 28, 1901.

To the Editor:—At the next meeting of the Vermont State Medical Society I am down for the discussion of a paper on "Dislocation of Hip During Labor." Can you give me any information on this subject, its cause, frequency, treatment, etc., or direct me to where it can be found?

C. S. S.

ANS.—This subject has been extensively discussed. There are a number of abstracts in the last few volumes of THE JOURNAL. The subject was discussed at length in the German Congress of Surgeons, in Berlin, in 1899, and was noticed in THE JOURNAL, May 13, of that year. Other articles are those of Whitman, in the *Medical News* of Oct. 7, 1897, noticed in THE JOURNAL of October 14; of Wirt, in the *Cleveland Medical Gazette,* April, 1900, and abstracted in THE JOURNAL of May 12; of Bradford, in the *Boston Medical and Surgical Journal,* October 25, noticed November 11; of Bade, in the *Centralblatt f. Chirurgie,* July 7. 1900. JOURNAL of August 4; Ducrocquet, *Bulletin Academy de Medicine,* May 29, 1900, in THE JOURNAL of July 7; and Ghillini, in the *Munich. Med. Wochen.* of March 26, 1901, and THE JOURNAL of April 27. There are probably one or two other more recent ones which will be easily found on reference to back numbers.

OKLAHOMA PRACTICE LAWS.

TOLEDO, OHIO, Sept. 28, 1901.

To the Editor:—I see in your last issue an item for granting certificates to the practice of medicine in the Territory of Oklahoma. Would you be so kind as to inform me in regard to the practice of medicine in this territory?

W. H. G.

ANS.—In Oklahoma one must be either a graduate in medicine or must pass an examination satisfactory to the Board. If not a graduate, one must give proof of having actually engaged in the practice of medicine for not less than five years. The fee for examination is $30. No person is allowed to practice medicine who is not of good moral character, or who is an habitual drunkard. In case the diploma is lost, proof by affidavit of the fact and the affidavit of two reputable citizens of the county in which the applicant resides, will be necessary. The fee for the registration of the diploma is $2. The secretary of the Board is Dr. E. E. Cowdrick, Enid, Oklahoma.

FRENCH AND GERMAN SCHOOLS.

NEW BEDFORD, MASS., Sept., 23, 1901.

To the Editor:—Please advise me from whom or where I can get information in regard to German and French medical schools and clinics.

E. E. F.

ANS.—There is no publication available in our language, so far as we know, that gives a full account of the medical schools and clinics in Germany. A number of years ago Dr. Hun, Albany, published a work on this subject, but it has gone out of print, and would probably not be reliable for the present time. The French periodical, *Le Progrès Médical,* publishes an educational number once a year, giving an account of the French schools, but we do not know of any giving the same information for Germany. The last issue of this kind was Nov. 10, 1900. Another is probably now nearly due.

OVARIAN EXTRACT.

ST. CLAIR, MINN., Sept. 30, 1901.

To the Editor:—Will you kindly state where I can find recorded the latest observations on the use of ovarian extract in the treatment of post-operative menopause?

C. J. H.

ANS.—We would refer the inquirer to Krusen's article in the *Johns Hopkins Hospital Bulletin,* of July, 1901.

SUBCUTANEOUS PARAFFIN PROTHESIS.

Findlay, Ohio, Sept. 25, 1901.

To the Editor:—In The Journal of July 27, 1901, p. 292, you gave an article by Gersuny on subcutaneous paraffin prothesis. I have tried to get the unguentum paraffin a number of places, but have failed. Can you tell me where I can get it? Also give me Gersuny's address. F. B. E.

Ans.—The material used by Gersuny is American white vaselin, which is soft at ordinary room-temperature. Gersuny's address is Vienna, in Austria.

The Public Service.

Army Changes.

Movements of the Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Sept. 5 to 25, 1901, inclusive:

Harry D. Belt, contract surgeon, from duty at Fort Trumbull, Conn., via New York City, to Havana, Cuba, for assignment in the Department of Cuba.

William Donovan, contract surgeon, now in New York City, awaiting orders, will proceed to Madison Barracks, N. Y., for duty at that post.

Rudolph G. Ebert, major and surgeon, U. S. Army, to report in person to the commanding officer, Vancouver Barracks, Wash., as post surgeon, relieving Lieut.-Col. J. B. Girard, deputy surgeon-general, U. S. Army.

Joseph H. Ford, lieutenant and asst.-surgeon, U. S. Army, leave of absence granted.

William W. Gray, major and surgeon, U. S. Army, leave of absence granted.

Charles R. Greenleaf, colonel and assistant surgeon-general, U. S. Army, leave of absence granted.

Eugene H. Hartnett, lieutenant and asst.-surgeon, U. S. Army, member of a board in New York City, for the examination of officers of the line for transfer to the Ordnance Department.

Luther S. Harvey, captain and asst.-surgeon, Vols., recently appointed and now at Holguin, Cuba, is relieved from duty in the Department of Cuba, and will proceed to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Herbert I. Harris, contract surgeon, from Fort Snelling, Minn., via New York City, to Havana, Cuba, for assignment in the Department of Cuba.

E. P. Howell, contract surgeon, leave of absence from the Department of the Colorado extended.

John F. Leeper, contract surgeon, now at Fort Leavenworth, Kan., will proceed to Jefferson Barracks, Mo., for temporary duty.

John R. McDill, major and surgeon, Vols., resignation accepted, to take effect Sept. 11, 1901.

Marion B. McMillan, contract surgeon, leave of absence from the Department of Cuba extended.

Clarence B. Millhoff, lieutenant and asst.-surgeon, U. S. Army, leave of absence granted.

Elbert E. Persons, lieutenant and asst.-surgeon, U. S. Army, to duty at Fort Snelling, Minn.

Henry du R. Phelan, captain and asst.-surgeon, Vols., recently appointed and now in San Francisco, Cal., will report for transportation to Manila, P. I., for assignment in the Division of the Philippines.

Irving W. Rand, captain and asst.-surgeon, U. S. Army, to duty at Fort Trumbull, Conn.

Henry I. Raymond, major and surgeon, U. S. Army, member of a board at Chicago, Ill., to examine certain persons for appointment as lieutenants in the U. S. Army; member also of an army retiring board.

Walter Reed, major and surgeon, U. S. Army, detailed as an additional officer to represent the Medical Department of the Army, at the annual meeting of the American Public Health Association, to be held at Buffalo, N. Y., Sept. 16 to 20, 1901.

George H. Richardson, contract surgeon, from Plattsburg Barracks, N. Y., to Fort Apache, Arizona, for duty at that post.

David M. Roberts, contract surgeon, now on duty at Fort Howard, Md., to proceed to Fort Sam Houston, Tex., for temporary duty, on the completion of which he will return to his proper station.

Frederick F. Russell, lieutenant and asst.-surgeon, U. S. Army, from Mayaguez, P. R., to New York City, reporting on his arrival by telegraph to the Adjutant-General of the Army for instructions.

H. Eugene Stafford, captain and asst.-surgeon, Vols., resignation accepted by the President, to take effect Sept. 20, 1901.

Richard P. Strong, lieutenant and asst.-surgeon, U. S. Army, former [illegible] to duty at the Army and Navy General H[illegible] Ark., revoked; he will report in person to the [illegible] S. Army, for temporary duty in his office, [illegible] which he will proceed to San Francisco, Cal., e[illegible] I., for duty as Director of the Government [illegible] Manila, P. I.

Eugene [illegible] and surgeon, U. S. Army, now in this city, will proceed to Fort Leavenworth, Kan., for duty at that post.

Fred R. Underwood, contract surgeon, relieved from duty at Fort Leavenworth, Kan., to proceed to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Timothy E. Wilcox, lieut.-col., and deputy surgeon-general, U. S. Army, member of a board in Chicago, Ill., to examine certain persons for [illegible] as lieutenants in the U. S. Army; member also of an [illegible]

Allie W. [illegible] and asst.-surgeon, U. S. Army, relieved from further duty at Fort Columbus, N. Y., to proceed to Mayaguez, P. R., for duty at that post.

Navy Changes.

Changes in the Medical Corps of the Navy, week ending Sept. 28, 1901:

Asst.-Surgeon F. A. Asserson, Asst.-Surgeon J. W. Backus ordered to the Naval Hospital, Cavite, P. I.

Asst.-Surgeon A. E. Peck, ordered to the *Manila.*

Asst.-Surgeon C. E. Burr, resignation accepted, to take effect September 25.

Asst.-Surgeon D. C. Bebe, detached from the *Marietta*, and ordered home to wait orders, when vessel is put out of commission.

Asst.-Surgeon E. J. Grow, detached from the *Castine*, when put out of commission, and ordered home to wait orders.

P. A. Surgeon E. M. Shipp, detached from the Naval Hospital, Cavite, and ordered to the *Celtic.*

Asst.-Surgeon W. L. Bell, detached from the *Celtic* and ordered to the Naval Hospital, Cavite, P. I.

Asst.-Surgeon J. W. Backus, detached from the Naval Hospital, Cavite, P. I., and ordered to the *Brooklyn.*

Asst.-Surgeon F. A. Asserson, detached from the Naval Hospital, Cavite, and ordered to the *General Alvas.*

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended September 26, 1901:

Surgeon S. D. Brooks, granted leave of absence for fourteen days from September 29.

P. A. Surgeon H. S. Cumming, granted leave of absence for thirty days, on account of sickness, September 26.

Asst.-Surgeon S. B. Grubbs, granted leave of absence for eleven days from September 25.

Asst.-Surgeon H. B. Parker, to proceed to Jacksonville, Fla., for special temporary duty.

Asst.-Surgeon W. C. Hobdy, to proceed to South Atlantic Quarantine as inspector.

Asst.-Surgeon F. J. Thornbury, relieved from duty at Dutc Harbor, Alaska, and directed to return to the States.

A. A. Surgeon L. P. Gibson, granted leave of absence for te days on account of sickness.

A. A. Surgeon E. B. Hallett, granted leave of absence for thre days from September 24.

A. A. Surgeon A. B. McDowell, granted leave of absence fo twenty days from October 12.

A. A. Surgeon Henry Owen, granted leave of absence for te days from September 24.

A. A. Surgeon S. D. Robbins, granted leave of absence for thirt days from September 6, on account of sickness.

Hospital Steward M. R. Mason, relieved from duty at Dutc Harbor, Alaska, and directed to return to the States.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plagu have been reported to the Surgeon-General, U. S. Marine-Hospita Service, during the week ended September 28, 1901:

SMALLPOX—UNITED STATES.

California: San Francisco, Sept. 1-15, 4 cases.

District of Columbia: Washington, Sept. 14-21, 9 cases.

Massachusetts: Boston, Sept. 14-21, 9 cases.

Michigan: Detroit, Sept. 14-21, 1 case.

New Jersey: Newark, Sept. 14-21, 18 cases.

New York: Sept. 14-21, Elmira, 2 cases; New York, 3 cases, death.

Pennsylvania: Lebanon, Sept. 8-15, 5 cases; Philadelphia, Sep 14-21, 38 cases, 4 deaths.

Wisconsin: Green Bay, Sept. 15-22, 1 case.

SMALLPOX—FOREIGN.

Belgium: Aug. 31-Sept. 7, Antwerp, 4 cases; Ghent, Aug. 31 Sept. 7, 1 death.

Brazil: Rio de Janeiro, Aug. 4-18, 114 deaths.

Colombia: Panama, Sept. 9-16, 12 cases.

Egypt: Cairo, Aug. 26-Sept. 7, 1 death.

France: Paris, Aug. 24-Sept. 7, 10 deaths.

Great Britain: Aug. 31-Sept. 7, Edinburgh, 1 case; London, 92 cases, 8 deaths.

India: Bombay, Aug. 20-27, 1 death; Calcutta, Aug. 18-24, 2 deaths; Madras, Aug. 10-23, 19 deaths.

Naples, Aug. 24-Sept. 7, 182 cases, 26 deaths.

Nova Scotia: Halifax, Sept. 14-21, 9 cases, 1 death.

Russia: Aug. 24-31, Moscow, 4 cases, 2 deaths; St. Petersburg, 4 cases.

Spain: Madrid, June 17-July 15, 6 deaths; Malaga, Aug. 31-Sept. 7, 5 deaths; Valencia, Sept. 3-10, 7 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, Aug. 4-18, 2 deaths.

Costa Rica: Port Limon, Aug. 1-Sept. 14, 12 cases, 6 deaths.

Cuba: Havana, Sept. 7-14, 1 case.

Mexico: Aug. 24-31, Merida, several cases; Progreso, 1 case.

CHOLERA.

India: Bombay, Aug. 1-27, 4 deaths; Calcutta, Aug. 18-24, 10 deaths; Madras, Aug. 10-23, 201 deaths.

Japan: Yokohama, Aug. 18-24, 1 case.

Straits Settlements: Singapore, July 27-Aug. 3, 2 deaths.

PLAGUE—UNITED STATES.

California: San Francisco, Aug. 29-Sept. 20, 4 cases, 2 deaths.

PLAGUE—FOREIGN.

China: Hongkong, Aug. 3-10, 10 cases, 12 deaths.

India: Bombay, Aug. 20-27, 203 deaths; Calcutta, Aug. 18-24, 32 deaths; Karachi, Aug. 11-25, 8 cases, 5 deaths.

THE TREATMENT OF MALIGNANT DISEASE.[*]

FREDERIC S. DENNIS, M.D., F.R.C.S. ENG.
Professor Clinical Surgery, Cornell University Medical College, New York City: Attending Surgeon to St. Vincent and Bellevue Hospitals.
NEW YORK CITY.

The treatment of malignant disease is of paramount importance. The questions of etiology, symptomatology and classification of malignant disease are insignificant as compared with the treatment. This subject can only be appreciated by a recognition of two salient facts: 1, the increase of malignant disease; 2, the universal mortality.

To better appreciate the vital subject under discussion it is pertinent to consider for a few moments the increase of malignant disease in order to better understand the importance of its treatment. Humanity at large, seeks for relief from this dreadful scourge, and humanity appeals to the surgeon for help, as he is the only one who can effect a cure.

The increase of cancer is a fact which as it is not understood, can not be explained. Through the kindness of Mr. Frederick L. Hoffman, of the Prudential Life Insurance Company, I am indebted for some information which has never been published, and which is as interesting as it is startling. For example, he has prepared some statistics upon the increase of cancer of the breast in Rhode Island and Connecticut, in Philadelphia, and in the District of Columbia. While these statistics are limited to cancer of the breast, they serve well our purpose, as a general basis of calculation, for cancer affecting other organs. These statistics show that for the past thirty years cancer of the breast has materially increased, and the rates have been calculated on the basis of 1,000,000 of population.

In Rhode Island the increase in the mortality of cancer of the breast has been 115 per cent., if we compare the period from 1876 to 1880 with the period from 1896 to 1900.

In Connecticut unfortunately the data do not go back further than 1882, so that strict comparison is not possible; but an approximate comparison indicates an increase of mortality since that date of 12 per cent.

In the City of Philadelphia the period from 1861 to 1865, compared with that of 1896 to 1900, shows an increase of 179 per cent. in the mortality of cancer of the breast. It is only fair to add that from the period of 1876 to 1880 to the period from 1896 to 1900 the increase was only 12 per cent., the explanation for which will be considered later.

In the District of Columbia there has been an increase in the mortality of cancer of the breast of 50 per cent. from the period of 1876 to 1880 till 1896 to 1900. The chart will enable one to see at a glance the increase in the mortality of cancer of the breast during the past thirty years.

Perhaps an illustration of the increase of cancer in this environment might be pertinent. In the City of Milwaukee in the year 1878 there were 25 deaths from cancer per 100,000 population. Levings assigns as an explanation of this condition the fact of "the increased average age of man, and the necessary and consequent increased prevalence of diseases like cancer, in which hereditary predisposition plays an important part." Whatever theory is accepted as to the cause of increase it matters little. The fact stands out in the foreground, in bold relief, that the disease is increasing, and this behooves the surgeon to continue investigations until he can ascertain the cause, and apply the remedy, to the disease.

The death rate from cancer for the United States in 1890 is 53 per 100,000 of population, for England 67, for Scotland 60, for Austria 52, for Ireland 45, for Prussia 43, for Italy 42.

If now, instead of countries, the different states of the Union are considered, it is found by the census report for 1890: Vermont 75 per 100,000, New Hampshire 69 per 100,000, Massachusetts 66 per 100,000, Connecticut 55 per 100,000; New York 53 per 100,000, District of Columbia 49 per 100,000; New Jersey 47 per 100,000, and Delaware 35 per 100,000.

In all of the calculations by states the age element is ignored. Therefore, in states like Vermont and New Hampshire, where the proportion is so great, allowance must be made for the fact that the emigration of the young people to the Western states especially leaves proportionately to New England a larger number of persons liable to death from cancer.

The increase average age of human life does not altogether account for the increase of cancer. There are no accurate life tables for this country, for a period of thirty years; but there are such tables in England, which may serve as a basis for calculation in this country. In the period from 1838 to 1854 the expectation of females at birth was about 41 years. In the period from 1881 to 1890 it increased to about 47 years. These figures show an increase of about 5 years, which is equal to about 12 per cent. It is upon such a calculation as this that Levings and others have offered an explanation of the increase of cancer to the increase of the average length of life. It is, however, erroneous to reason from this slender basis of facts, because, in the first place, the expectation of life affects the entire period of life, and, in the second place, the actual gain made at birth may and, as a matter of fact, does, affect only the you age period. In other words, the expectation of lif have been increased at birth, while the decrease may have taken place at older years, or at the time when the patient has reached the cancer age. This has actually been the case, since for England and Wales the expectation of life at 45 years and over is now somewhat less than it was fifty years ago.

---

[*] Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker, and A. J. Ochsner.

We must look, therefore, to some other cause to explain the increase of cancer than the statement of the increase average length of life.

On the other hand, it is maintained by some that cancer is increased apparently and not in reality. Newsholme claims that this apparent increase is due to greater accuracy in the returns of death certificates, and to the diminution of the number of death certificates in which indefinite headings are employed. He claims that if we follow the statistical method which is adopted to demonstrate the increase of cancer, along similiar lines we can prove that the number of individuals dying from old age has enormously decreased. This is erroneous, because death certificate returns which formerly were made out with old age as the cause of death, now have the real cause assigned to them.

In other words, that the increase in the number of correct death certificates, and the decrease in the number of *incorrect certificates*, bring out apparently the fact that cancer is on the increase, whereas it may be the reverse. This is in marked contrast to Park's statement that if in the next ten years the increase of cancer mortality is maintained there will be more deaths from cancer in New York State than from tuberculosis, smallpox and typhoid fever combined.

There are some very interesting data which show the increase of cancer of the breast in certain periods, each period consisting of five years. In the City of Philadelphia, if we start with the first period covering the years 1861 to 1865, inclusive, the increase in the mortality of cancer of the breast down to the period of 1896 to 1900 is 179 per cent.; 150 per cent. of the 179 per cent. was gained up to the year 1880. The increase in the mortality of cancer of the breast from the fourth period ending in 1880, to the five years ending in 1900, is only 12 per cent. In other words, the brilliant diminution in the increase of cancer of the breast in Philadelphia is due to the magnificent results of surgical work in that city. If this standard is kept up, in the five years to come the surgery of *Philadelphia* will reduce the mortality of cancer of the breast to a percentage which will be phenomenal.

In the District of Columbia the mortality of cancer of the breast in the four periods of five years each, beginning with the period of 1876 to 1880, till the period of 1896 to 1900, is 50 per cent.

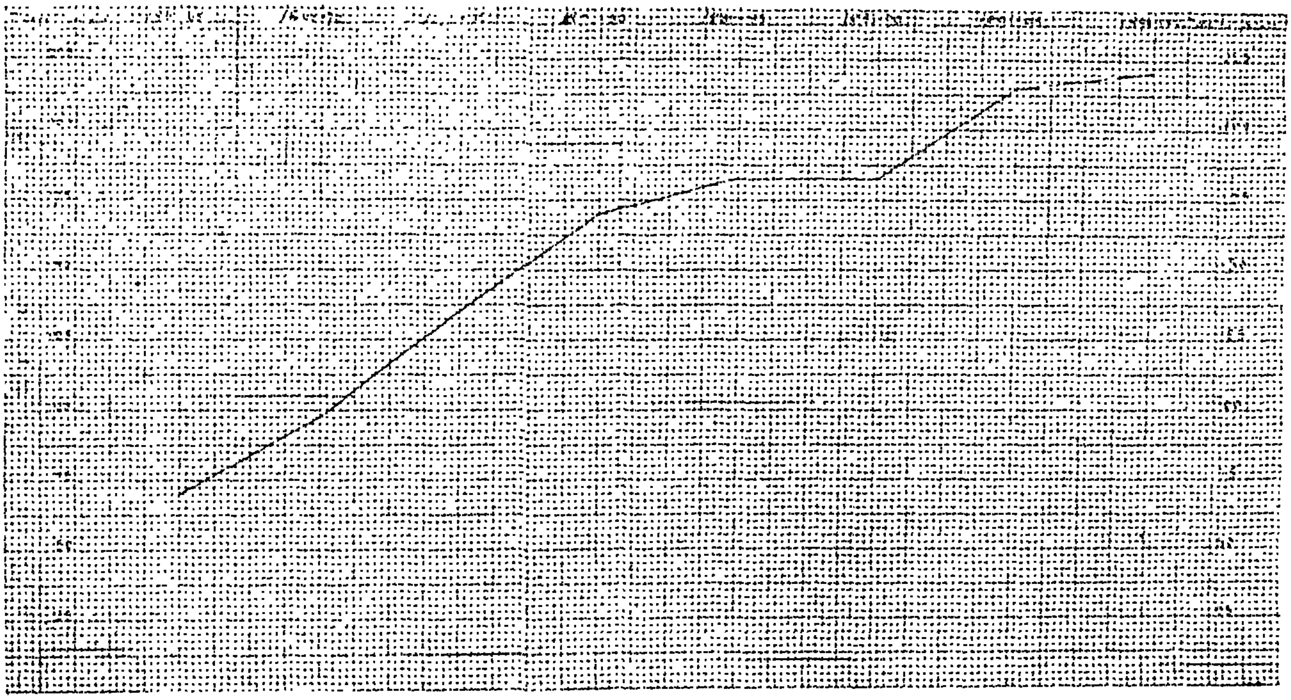
In Rhode Island the increase of mortality of cancer of the breast for this same extent of time is 115 per cent.

In Connecticut the data do not extend far enough back to make a comparative estimate; but from the sixth to the eighth periods, i. e., from 1882 to 1900, the increase is 12 per cent.

It seems irrelevant to dwell at length upon the actual or apparent increase of cancer, the paramount subject is the treatment, since in England alone there are 7,000 deaths annually from carcinoma, and 30,000 patients suffering at all times from the disease. In the United States, in 1890, there were over 18,000 deaths from carcinoma; in fact, there were probably more than 18,000, since in many states no registration system provides for accurate mortality returns, and in all probability 25,000 deaths is not too high an estimate.

Cancer causes nearly half as many deaths in the United States in one year as are caused by accidents and injuries of all kinds and descriptions; and it is responsible for more deaths, in one year, in the United States than the sum total due to erysipelas, tetanus, hydrophobia, lightning, appendicitis, gunshot wounds and joint disease, together with other well-known surgical affections. These facts emphasize the importance of the subject under discussion.

Before discussing the treatment of malignant disease by surgical interference, *it is necessary to review*, in a cursory manner, the principal methods of treatment at



MORTALITY FROM CANCER OF THE BREAST AMONG FEMALES IN RHODE ISLAND, CONNECTICUT, PHILADELPHIA AND DISTRICT OF COLUMBIA. PREPARED BY MR. FREDERICK L. HOFFMAN.

present in vogue. Reference to these methods is made in order to complete the list of recognized plans of treatment. The different methods to be described before discussing the surgical operations are: 1, the *x*-rays; 2, electricity; 3, caustics; 4, drugs, and 5, toxins.

The Roentgen Rays.—Dr. Francis H. Williams reports the use of the *x*-rays in the treatment of cancer. He employed them for five minutes daily, but thinks that it is not necessary to make such frequent exposures. He reports excellent results in those cases where the cancer was superficial. Dr. Williams believes that the *x*-rays will prove of great value in cases of cancer involving the deeper structures.

The conclusions at which Dr. Harvey P. Towle arrived, in reference to the *x*-rays as a therapeutic agent, are so concise and pertinent that I shall quote them verbatim: "1, that the real nature of the *x*-rays is not yet determined definitely, nor is it known whether the therapeutic action following their use is due to the action of the rays themselves, or something of electrical origin accompanying them; 2, that the treatment is not without danger unless the greatest care is used; 3, that the effects of the *x*-rays remain for a long time, and recovery is very slow; 4, that whatever may be the exact origin of the effects produced, a definite reaction is caused in the skin by the use of the *x*-rays; 5, that the changes induced in the skin are similar, histologically, to those seen in ordinary inflammation; 6, that the *x*-rays are not proved to have any bactericidal power; 7, that their therapeutic effect is probably due to the inflammation excited; 8, that hair can be removed by their use, and that lupus and several other diseases can be healed over; 9, that in a few reported cases we may fairly assume that a permanent cure has been effected; but that in a majority of the reported cases, too little time has elapsed to rule out the possibility of a return of the disease; 10, that the effect of exposure to the *x*-rays is so extraordinarily slow in disappearing that months should elapse before an absolute cure is assumed; 11, that while the permanency of the cure effected may perhaps be doubtful as yet it is certainly desirable to experiment further."

The treatment of malignant growth by the *x*-rays is therefore still in embryo, and the time is too short to predict, with any degree of certainty, as to the permanency of the few cures that have been claimed; our knowledge of the modus operandi of the *x*-ray is still shrouded in mystery. The serious objections to the use of the *x*-rays in the treatment of malignant disease can, in a measure, be overcome, by shortening the length, and diminishing the frequency of the exposures, and by more accurate knowledge as to the distance of the tube from the tumor.

How it will cure malignant disease no one knows beyond the fact that the *x*-ray "acts by its electric action or by the electrolytic discharges generated in the integument by a high potential current." All that can be said, at the present time, is, that the results of treatment by the *x*-rays are still *sub judice* and that more data must be forthcoming before any opinion can be expressed as to their value.

Electricity.—The use of electricity in treatment of malignant disease is only mentioned for the purposes of condemnation. In this field of surgery it has no place as a therapeutic agent, and while its use is of value in certain diseases, in this special department it is worse than useless.

Caustics.—The use of caustics is limited to those forms of epithelial ulcers which are situated upon the skin and are very superficial. In this variety of epithelioma, as well as in myxomata, situated upon the surface of the integument, the employment of caustics has been attended by a certain amount of success. There are no statistics as to the permanency of the cure that I have been able to find, with the exception of here and there an isolated case. I have never seen an epithelial ulcer upon the skin the entire removal of which, by free incision, is not preferable to the application of escharotics. I have had good results in small myxomata treated by fuming nitric acid; but, as a rule, my experience has taught me that the remedy is unsurgical in most cases, and that only in exceptional forms of malignant disease is the use of escharotics to be resorted to as a means of permanent cure.

When it comes to malignant disease, such as sarcoma of the bone, or cancer of the breast, I deem it unsurgical to subject the patient to such treatment. In these cases surgical intervention is the only proper resource. I am aware that there are men in the regular profession who treat the different varieties of malignant disease by caustics; but I have searched the literaure of surgery in vain for any reports of permanently cured cases, and I have been unable to obtain by personal communication any data upon the great question of permanent cure. If these men have their statistics they should publish them for the benefit of the profession, and on behalf of suffering humanity.

The arguments used by the advocates of the caustic treatment appear fallacious in the extreme, since the pain of the caustic is nearly as severe as incision, and lasts much longer. The voidance of an anesthetic is claimed as another argument in favor of caustics; but with Schleich's method of anesthesia in the smaller growths, and by the use of nitrous oxid gas or oxygen, in the larger ones, this objection, so strongly urged, is entirely overcome.

Even in amputation of the breast, in aged patients, I have employed the gas with no pain, but little shock and no disagreeable after-effects of anesthesia. The avoidance of shock and hemorrhage are also claimed by the advocates of the caustic treatment; but the shock of incision in local anesthesia, or under the influence of gas, is not greater than the prolonged agony caused by escharotics, besides the dangers of secondary hemorrhage are obviated, as well as a long period of convalescence incident to the repair of a sloughing wound.

The employment of caustics in the treatment of malignant disease, with but rare exceptions, is therefore to be condemned; because the method is attended by pain, does not effect permanent cures, causes extensive sloughs with the consequent dangers of secondary hemorrhage and septicemia, and requires great loss of substance, which takes a long time to repair and then often in an unsatisfactory manner. In no way can the caustic remove diseased tissue which the scalpel can not better accomplish, and in no way is the healing better or the cure as permanent as by a clean aseptic operation.

Drugs.—Launois, in February, 1901, reported promising results in the subcutaneous injection of chlorohydrate of quinin in inoperable cases of malignant disease. Berger employed the serum of Wlaiev and maintained that the functional symptoms were improved, but that the growth itself was in no way affected. Petrini injected 5 centigrams of this serum according to Gautier's method, and gradually raised it to 12 centigrams in a case of multiple sarcomata, and claims to have cured the case in six weeks. There is no information as to the permanency of the cure, and therefore no conclusion can be drawn upon this case owing to insufficient data.

Tuffier recommends the use of the drug; but he gives no cases from which any conclusions can be drawn.

Formalin has been hypodermically injected; but this plan of treatment has only proved a failure. In fact, it seeems a waste of time to review any more remedies suggested for the cure of cancer. They are all of one class, and they are all followed by failure. They are all injurious because their employment occupies valuable time and only postpones an operation, the only method of treatment worthy of adoption.

Pyoktanin has been suggested as a remedy by Mosetig Moorhof, who employed it with a view to destroying the nuclei of the proliferating cells of cancer. This remedy, like all the others, afforded, in some cases, temporary benefit; but I am unable to find any reports regarding the permanency of the cures.

Thyroid extract has recently been extolled as a curative agent. I have tried this drug in a large number of cases, but in no one as yet have I seen a permanent cure. Thyroid extract will retard the rapid ulceration in cancer; it will relieve the pain in some cases; it will control the hemorrhage; it will dispel in many cases the disagreeable odor arising from the infection; it will prolong life; it will make the patient comfortable, but it will not cure. This is all that can be expected from thyroid extract, and this drug stands as a prominent example of all the drugs that have been introduced into practice as specifics in malignant disease.

Chian turpentine has been extensively employed as a curative remedy in cancer. This medicine was introduced by Clay of Manchester, and his reports are such as to attract attention to its use. Personally, I have been greatly disappointed in the remedy, as I have never seen a case of cancer cured by it; although, in some instances, I have observed a diminution in the pain, ulceration, hemorrhage and odor. This, however, has never been so well marked as in the case with the thyroid extract.

Methylene-blue has been highly extolled by some surgeons. I am frank to confess that notwithstanding its administration in many cases I have never seen a cure effected by it, and only in a few instances any temporary benefit. It decreases the odor to a certain extent, perhaps arrests in a certain degree the ulceration, and in this way controls the secondary hemorrhages. At one time I was quite confident that it would prove of signal value; but a more extended experience has led me to believe that it has failed to accomplish that which was expected of it.

Potassium iodid in very large doses has been employed with a view to curing sarcoma. Some authorities have reported cases of cure following the use of this drug. I must confess that I have never seen a case of sarcoma cured by potassium iodid. I have seen some inflammatory neoplasms disappear, and can recall several cases of absorption of exudations which were large enough to produce pressure symptoms.

In one case of complete hemiplegia 600 grains of the iodid given daily, and continued for several weeks, caused the intracranial exudation to absorb, and complete recovery followed. It is now over ten years since the attack. In still another case I saw a mono-brachial paralysis disappear after using the iodid in several hundred grain doses daily. These cases, however, had without doubt a specific history, and such neoplasms must not be confounded with sarcoma, although the histologic formation may be very similar. It is precisely in this class of cases that errors of diagnosis have been made, and consequently cures reported which were supposed to be sarcoma, when in reality the growths were not malignant.

The *toxins* of the streptococcus erysipelatis and the bacillus prodigiosus mixed is a method as advocated by Fehleisen and Coley. The treatment is carried on by hypodermic injections of small and increasing doses. The best results are obtained in the mesoblastic growths, and the giant-celled sarcomata. It is not to be employed as a substitute for operation and only in cases where the tumors are inoperable. Coley's article on the results of this treatment is worthy of perusal. The writer has personally seen but temporary benefit from this method, but in no case a cure.

The writer referred to Coley's paper,[1] in which he gave the results of 140 cases of inoperable sarcoma treated with the mixed toxins of erysipelas and bacillus prodigiosus. In 24 of these the tumor completely or partially disappeared as a result of the treatment. In 84 of this series the sarcoma was round-celled; in 21 spindle-celled; in 9 melanotic; 2 chondrosarcoma; in 12 the type of cell was not stated, though the diagnosis was confirmed by the microscope; 6 were inoperable sarcoma, the diagnosis resting upon clinical symptoms, combined, in most cases, with a history of repeated recurrence.

In 40 cases of the round-celled, or slightly less than half, more or less improvement was shown by decrease in size or cessation of growth. In only 4 of these was the treatment permanently successful. Of 21 cases of spindle-celled sarcoma 10 disappeared entirely; all the remainder showed marked improvement. In no case of melanotic growth more than temporary improvement was noted. At the time of this report 8 cases had remained well from 3 to 6 years; 9 from 1½ to 3 years.

In addition to these personal results, the paper contained a summary of results in 35 cases successfully treated by other surgeons employing the same method. Of these 35 cases, 10 were round-celled; 10 spindle-celled; in 5 the diagnosis was clinical only; in 5 there was, in addition to the clinical signs of sarcoma, a history of recurrence after operation; in 4 the diagnosis of sarcoma was confirmed to microscopic examination, but the type not stated; 1 was endotheliosarcoma. Of these 35 cases 26 disappeared completely; 2 others decreased so much that only a small node was left, which was easily excised. One of the latter cases was well three years and the other one year at the time of report. Of the 35 cases referred to, 14 were well over two years, and 6 cases over three years. The object of the paper, the author said, was to determine, if possible, from a careful tracing of the successful cases, whether the action of the toxins upon sarcoma is to be regarded as of temporary or permanent value; in other words, whether or not it is entitled to be called curative. At the time of his report in 1898, 8 of his personal cases had remained well from three to six years; he stated that this number had now increased to 16 that had remained well from three to eight years. Of these, 2 recurred, one at the end of three and one-quarter years, and the other after eight years, both proving fatal. The diagnosis was confirmed by the microscope in all cases with two exceptions. In these instances the history of the cases with the clinical appearances made the diagnosis of sarcoma unquestionable. The type of tumor in the 16 cases that passed the three-year limit, was as follows: Spindle-celled sarcoma, 8; spindle-celled (probable), 1; round-celled sarcoma, 2; mixed-celled sarcoma, 2; epithelioma, 1; sarcoma (clinical diagnosis only), 2. It is worthy of special note that two of the successful cases now well—three and three-quarters and four and one-quarter years, respectively, were sarcoma of the parotid gland. Butlin, in his last edition of "Operative Treatment of the Parotid Gland" states that "up to the present time there are very few instances of cure by operation of undoubtedly malignant disease of the parotid." In my two cases treated by the toxins the diagnosis was not only confirmed by a competent pathologist, but further by a history of repeated recurrences after operation.

---

[1] The Journal A. M. A., Aug. 27, 1898.

The results thus far, he stated, seem sufficient to warrant advising the treatment as a routine measure after all operations for primary sarcoma. While the treatment is not recommended in carcinomatous growths, it has been the experience of the writer that in many cases the toxins exert a marked inhibitory influence in carcinoma, although it is rarely curative. The only cases of carcinoma in which the toxins are likely to prove of much value, I think, are those in which they are used after primary or secondary operation, as a prophylaxis against recurrence. Up to the present time sufficient experience is lacking to justify one in making any definite statements as to how much may thus be accomplished.

The writer still believes that the action of the toxins upon malignant tumors can be explained only upon the theory that such tumors are the result of some infectious micro-organism, and this view is strongly supported by the recent expressed opinion of Czerny.

Cancroin, a toxic product obtained from cancerous tissue, has been injected by Adamkiewicz. This remedy has not cured cancer, but in some cases has secured a minimum of benefit. This brief summary of the other methods of treatment has cleared the way for the discussion of the treatment by surgical intervention, which is really the only method that offers any prospect of success.

SURGICAL INTERVENTION.

Surgical intervention is the only resource, since all drugs have proved ineffectual, and all other methods practically of no avail. It is, however, only successful when the disease is taken early in its history, and when the operation is radical in its character. Delay in operating is attended with great mortality. The more radical the operation the more certain its cure. Six months from the beginning of the disease is the utmost limit of time; statistics in my own cases prove that after the expiration of this time results are uncertain. An early, and a radical operation, therefore, are the essential requisites for cure in malignant disease.

Various methods of treatment have been indulged in from time to time; but radical surgical interference is the only method that meets with encouraging results. That surgical operation will permanently save a patient is demonstrated by a study of the cases presently to be reported.

In every instance the names of the physicians who were present at the operation are given for reference, and accompanying each case is the microscopic report of the tumor by an eminent pathologist. The exact date of operation, the situation of the tumor, the main points connected with the clinical history are reported. No case is given in which at least three years have not elapsed since the time of the operation. In many of the cases from 10 to 22 years have transpired without the slightest evidence of return. They are reported to prove the value of surgical intervention over all other methods of treatment, and at the same time to call attention to the conditions essential to success. The report should also offer hope to those who are the victims of malignant disease, since surgical interference is the only salvation for these patients.

Before discussing the subject of statistics in reference to permanent cure in malignant disease by surgical operation, I wish to say frankly, that I consider them of questionable value. They do not afford the accurate information of which the searcher after truth desires. I make this statement after much thought, deliberation and personal experience, and I am fully aware of the opposition it may invoke. My reasons are these: 1. There is no unanimity among surgeons in regard to the elimination of cases for statistical purposes; for example, one surgeon will thrown out a large number of cases on the ground that they were inoperable, which fact was ascertained in the attempt to remove the disease, and therefore they are not to be included in the final list as determining the result. 2. Another surgeon will throw out a large number for the reason that the histories are unknown, or include some cases with the clinical history of cancer without microscopic verification. 3. The types of malignant disease have such a wide variation that tumors of one class which are more rapidly malignant than those of another class are placed in the same category, and such a comparison without doubt is unfair. 4. The causes of death are ascribed in some cases to acute sepsis, while these cases died, in reality, from too prolonged anesthesia, the deferred shock of which rendered the patient less resistant to overcome any sepsis. 5. The number of cases of malignant disease, affecting one organ for example, upon which an estimate is to be based, is too limited to convey by statistics any reliable information as regards mortality or permanent cure. For example, I have had 100 per cent. of permanent cure in certain malignant disease affecting a certain organ; but I had only one case. For these, and many other reasons, I feel convinced that statistics upon this special point are unreliable; in other words, they do not furnish us with the entire truth.

With these remarks as a preface I will give in a brief way some results from my own personal experience. I would add that these statistics have been verified by a learned mathematician and scholar who did not possess a medical degree, and therefore was ignorant of any information bearing upon the subject that the figures might show. I would further add that it is possibly a case may have been reported wrongly, or a clerical error may have occurred in keeping a history of so many hundred cases. As far as I know, however, the reports are accurate.

The two questions of mortality and permanent cure may be stated in the following terms. In the cases reported prior to 1891 at the meeting of the Congress of American Physicians and Surgeons, there was no mortality in amputation of the breast for cancer or sarcoma, or for any other cause with the exception of two cases of hemophilia. There was no mortality in the operation for removal of epitheliomata or sarcomata of the skin. There was no mortality in the operation for removal of sarcoma affecting the glands, and likewise the superior maxilla. There was one death in excision of malignant disease of the intestine, and also one death following amputation of the hip-joint. In reference to the percentage of permanent cures following the operation for the removal of cancer of the breast there was 45 per cent. of permanent cures up to 1891, and in the last series of 15 cases the percentage was 83 per cent. of permanent cures of over 3 years' standing and 75 per cent. of permanent cures in cancer of the face, including epithelioma of the lip.

In regard to sarcoma there was 85 per cent. of permanent cures in sarcoma of the breast, and 92 per cent. of permanent cures in sarcoma of the glands, 100 per cent. of permanent cures in sarcoma of the superior maxilla, 92 per cent. of permanent cures in sarcoma of the long bones. There was, finally, 100 per cent. of permanent cures in simple sarcoma involving the skin.

In no instance have I used the expression permanent cure when three years have not elapsed since the operation, and in nearly every case the period has been over seven years, and in a few up to twenty-two years to the present time. I have not collected my cases since this last report, but hope to do so at some future time.

Let us now return to the more important question which is: Can any cases be reported that have been entirely cured, and, if so, how many, and of what character was the malignant disease? It seems to the writer that positive information upon this vital point is worth more than all the statistics bearing upon the percentage of curability of malignant disease. It is the absolute fact of permanent cures that interests the surgeon and the laity.

The writer reports 87 cases of malignant tumors in patients upon whom he has operated, and at least three years, and in many of the cases ten, and in some twenty-two years have elapsed without recurrence. The list includes 48 sarcomata and 39 carcinomata, making in all 87. To this list a sufficient number of cases can soon be added, which will make the list at least 100, but a few months are lacking at present to have these cases reach the full three-year limit. These cases place beyond all doubt the question as to the possibilities of a cure in malignant disease.

These cases are reported as an encouragement to surgeons in their attempts to save human life, and also as a ray of hope to the unfortunate victims of malignant disease. It is possible under certain conditions for surgery to offer to patients afflicted with this terrible scourge that destroys annually so many lives, and blights so many homes, a cure for their malady. These tumors are upon exhibition at the Pathological Exhibit, and also the microscopic slides with sections.

Each one of these cases has been carefully watched, and the work necessary to make these statistics complete has been a labor fraught with the greatest difficulty. The satisfaction of knowing that surgery can cure these malignant growths repays the writer for his years of labor in tracing these cases down for a period of a quarter of a century to the present time.

In these 87 cases of malignant tumors operated upon, and cured by the speaker, it may be of advantage to classify them in a general way, so that some idea can be formed of the success which surgical operation can expect in these diseases of such frightful mortality.

1. *Sarcoma of Superior Maxilla.*—I am unable to find any satisfactory reports upon permanent cures in sarcoma of the superior maxilla. My cases of permanent cure number 5, in which the shortest period is eight years, and the longest is eighteen years.

2. *Sarcoma of Glands.*—I am unable to find a satisfactory report of cases of permanent cure in sarcoma of the glands. My cases number 7, in which a permanent cure has taken place, the shortest period being eight years and the longest twenty-one years.

3. *Sarcoma of the Skin.*—I am unable to find any satisfactory reports upon the results of treatment in sarcoma of the skin. My cases number 22 in which a permanent cure has taken place, and in which the shortest period is eight years and the longest is sixteen years. One case is included in the list with an explanation, since, in 1891 I operated on the patient for the first time, and at present she is alive. I have operated upon her over forty times for the relief of multiple sarcomata of the skin during the past eleven years. For eleven years she has been willing to submit to operations, and at the present time is without any new outbreak; since sufficient time has not elapsed from the date of the last operation she can not strictly be as yet in the category of permanent cures. Since the past few years she is comparatively free from any return and there is every prospect of cure in her case. This case is most remarkable as one illustrating the principle that as long as the patient will allow operations they should be performed, because there is a chance of permanent cure even in these cases.

4. *Sarcoma of the Breast.*—I am unable to find any satisfactory reports of sarcoma of the breast as distinguished from carcinoma of the breast. My cases number 6 in which a permanent cure has taken place, the shortest period being seven years, and the longest twenty-two years.

5. *Sarcoma of Bones.*—I am unable to find cases of permanent cure of sarcoma of bones by any other method of treatment than by surgical intervention, with the exception of those reported by Coley. In regard to this method, mention has already been made. Butlin reports 29 cases of sarcoma of the leg with a mortality of 30 per cent. in the operation itself, and only one single case could have been said to have been completely cured, taking three years as the standard of time. This high rate of mortality, in the operation itself, is a most astonishing fact, and is only surpassed by one still more startling, which is that out of this original list of 29 cases only one single case was reported by him as having been completely cured.

My cases of sarcoma of the leg number 8 in which there was a permanent recovery, the shortest period being sixty years and the longest thirteen years.

The treatment of sarcoma of the long bones is simple, because there is but one operation, and that is amputation. From an experience derived from a number of these cases of sarcoma of bone, and from opinions formed after careful study of the cases of others, I am more and more impressed with the fact that amputation is the only operation which should be contemplated. I refer to sarcomata of the long bones. The operation of exsection or enucleation, and an application of caustics are, in my humble judgment, productive of harm; because the disease is not, as a rule, radically removed by these methods, and oftentimes the tumor returns very rapidly, and the operation seems only to add fuel to the fire.

I believe that in all cases of sarcoma of the long bones amputation should be decided upon at the earliest period possible, and the operation performed without delay. At the point of election I would suggest an amputation which would remove the entire bone affected, whether it be a subperiosteal or central sarcoma. This necessitates an amputation of the lower part of the thigh in case the tibia or fibula is the seat of the neoplasm. It necessitates an amputation of the hip-joint when the tumor is subperiosteal, and involves the shaft of the femur. In view of the great mortality of hip-joint amputation, a possible exception might be made in case of a central sarcoma of the condyle of the femur which was recognized early, and which was small in size. By amputation in the lower third of the femur in sarcoma of one of the bones of the legs, the popliteal glands are thus removed, and while this point would concern us more if the disease were cancer, yet I have seen a case of sarcoma affecting those glands.

The remedy of amputation which is suggested, is a severe one; but the disease for which the amputation is performed is a uniformly fatal one if left to nature, and in view of the great malignancy of sarcoma, I believe the operation should be the most radical one consistent with a due regard for the life of the patient during the immediate performance of the operation. It must be remembered that the patient is suffering from a uniformly fatal disease, and the chances of escape from it are in proportion, within proper limits, of course, to the distance at which the limb is removed from the seat of the malignant tumor. Finally, I trust that I have been sufficiently clear upon the following points:

1. The importance of early recognizing the disease and the necessity of complete removal of the limb, including the entire bone affected, by amputation without delay.

2. The importance of carefully watching the subsequent history of patients upon whom an operation has been performed for the removal of sarcoma.

3. The importance of a microscopic examination of every sarcoma. Surgeons are of one opinion upon this point, that a microscopic examination is a *sine qua non* to insure the tabulation of a case for purposes of study.

4. The importance of a radical operation in these cases of malignant sarcomata affecting the long bones of the extremities, and the condemnation of partial enucleations and the use of caustics and plasters.

5. The importance of encouragement to patients suffering from malignant disease of the long bones, on the ground that early and radical operations, even in the most malignant cases, may result in perfect cure.

6. *Carcinoma of the Skin.*—I am unable to find any satisfactory reports of permanent cures in carcinoma of the skin. My cases number 19 in which there was a permanent cure, the shortest time being five years, and the longest twenty-one years. In this group is included a case of carcinoma of the ileum and cecum with resection of six inches of the bowel and a subsequent anastomosis with a Murphy button. It is now nearly four years since the operation and the patient is well and at work.

7. *Carcinoma of the Breast.*—My cases number 20 in which a permanent cure has taken place; the shortest period is four years and the longest thirteen years. Each one of these 20 cases is alive to-day and with no return, or recurrences, or metastases.

The result of the treatment by surgical interference shows, therefore, that these 20 cases have been permanently cured, and no other method or plan of treatment can furnish 20 cases that have been subjected to the test of so many years of immunity.

If now the 6 cases of sarcoma of the breast, of which mention has been made, be added to the 20 cases of cancer of the breast, there are 26 cases of malignant disease of the breast cured by surgical operation, the shortest period being four years and the longest twenty-two years.

CARCINOMA OF THE CECUM.

WITH REPORT OF CASES IN WHICH THE CECUM WAS REMOVED FOR MALIGNANT DISEASE.*

WILLIAM J. MAYO, A.M., M.D.
SURGEON TO ST. MARY'S HOSPITAL.
ROCHESTER, MINN.

Ileocecal carcinoma is not an infrequent malady. Ewald in a collection of 1148 cases of intestinal cancer found 64 in the cecum and 26 in the ileum, and more than half of the latter involved the ileocecal valves. Sutton says that of 100 cases of intestinal carcinoma 75 will involve the rectum, 23 the large intestine and but 2 the small bowel. Frank's table shows that two-thirds of all cancers of the large bowel involve the cecum and sigmoid flexure, and in about equal proportion. From these statistics it can be estimated that 7 per cent. of all malignant diseases of the bowel involve the cecum. Sex does not seem to have much significance. The average age of cases of carcinoma of this organ is somewhat younger than malignant disease in other parts of the body, and while not frequently found in the young it is sufficiently common to warn us against laying too much stress on the years of the patient.

Among the most frequent of the attributed causes is constipation, but if this is an important etiologic factor it would seem that the disease would affect females more often than males; yet this is not the fact. Maylard states that primary carcinoma of the intestine is always of the columnar-cell variety and Furnival points out the frequency of colloidal changes, particularly in the young. Lymphatic infection is found in less than one-half of the cases dying from intestinal carcinoma. Haussman, in 112 collected autopsies, found that 55 were limited to the gut, the remainder showing lymphatic involvement in 36 cases and in 21 cases general infection. More than one growth is seldom discovered, although two or more points of disease have been reported; whether all were primary or from a single source of infection and carried to the situations found by implantation or arterial emboli it is impossible to state.

The disease most frequently originates at the ileocecal juncture and has the usual tendency of all carcinomata of the large bowel to form a ring-like constriction, although a considerable tumor may exist without obstruction. The duration may be very prolonged and its course before active obstruction supervenes is usually slow. Briddon reports a case of twelve years' probable existence. Death usually results from obstruction or perforation, the latter either just above the stricture and close to it, or at some point in the cecum from distension; perforation is somewhat more frequent (7 to 4).

The distension ulcer in the cecum is similar in pathology to the distension ulcers in the small intestine about which Kocker has written so interestingly. The symptoms of malignant disease of the cecum are colicky pains, constipation alternating with diarrhea and progressive wasting. A tumor may be felt in some cases.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker, and A. J. Ochsner.

In the later stage intestinal peristalsis can be plainly seen through the attenuated abdominal walls and is usually accompanied by marked gurgling. Other cases present symptoms of chronic appendicitis with an induration indicating a small inflammatory deposit about the appendix. This was true of two of our cases. As the obstructed material is largely accumulated in the small bowel, symptoms of gastro-intestinal irritation are more marked than if the large bowel only was involved. A few cases are ushered in without premonitory symptoms by an attack of acute obstruction. König, Korte, Barton and others report cases in which an acute intussusception was the first sign of trouble.

The differential diagnosis between malignant stricture of the cecum and simple or tuberculous strictures may be impossible without exploration. In a paper on "Localized Tuberculosis of the Intestine" read before the Minnesota Academy of Medicine, Feb. 1, 1899, I reported three cases of tuberculosis of the cecum, and I have met with one additional case since that time. In these cases the foul discharges from the bowels, slight but constant temperature, tendency of the tuberculous mass to soften, taken into consideration with the previous history made a diagnosis possible, although the obstructive phenomena were essentially the same.

Cases of chronic inflammatory thickening of the cecum have been reported giving much the same signs and are in some cases, at least, syphilitic in origin. Impactation of feces in the cecum is not so very infrequent and may remain months, if not years, without dislodgement. In one case which I examined in an inmate of the Rochester State Hospital for the Insane, some twelve years ago, such an impactation was known to have been present for several years and finally by atrophy necrosis ulcerated to the surface of the body. Dermoid or other tumors of the abdominal muscles on the right side may confuse the diagnosis. In the one case of dermoid which I have seen the differentiation was most difficult. Dermoids are very rare and usually occur in the female following a labor. There is no history of intestinal obstruction.

Acute obstruction of the bowels is a frequent complication of the malignant process and its relief a prerequisite to a successful outcome. Treves, speaking of intestinal obstruction generally, says that he reduced his mortality 50 per cent. by relieving the distended intestine above the obstruction. This has been done by a simple incision or aspiration (Grieg Smith) or the use of Paul's tubes. The common method of relief has been that of forming a temporary artificial anus and in the large intestine necessarily in this manner. In such cases three operations are demanded: 1, relief of the obstruction by the artificial anus; 2, resection of the diseased area, and 3, closure of the anus, and this last has a mortality of its own. Makin collected 39 intestinal resections for the closure of an artificial anus —21 were cured, 3 uncured and 15 died.

From an operative standpoint the ileocecal coil should be independently considered. In cancerous or other obstruction of either the large or small bowel the normal condition above and below the disease is identical, but in this situation the small bowel empties its contents in a fluid state into the large intestine, in which the feces assume solid form. The question is not one of ordinary intestinal union in which two parts of similar bowel are joined, but one in which by reason of the dissimilarity an anastomosis can be effected under very favorable circumstances.

In ileocecal obstruction, the ileum can be readily joined laterally with the transverse colon. The obstructed intestinal contents are fluid and do not endanger the union as is the case with the solid accumulations in the large bowel, and the size of the receiving intestine and its nearness to the anal orifice gives it all of the advantages of an artificial anus on the surface of the body. The union can be effected at a point sufficiently high on the ileum to secure healthy bowel for approximation. There is also the great advantage in that the communication is permanent. The extirpation when performed later is more easily effected, both ends of the intestine being turned in and closed. We have performed ileocolostomy for various causes six times, in this manner, using the Murphy button, and all recovered from the operation. In four of these cases nothing was attempted in a radical way on the diseased part, the discharges draining satisfactorily from either side of the obstruction. Exclusion of a portion of the intestine can be safely accomplished provided there is some exit for the secretions of the excluded part, but, as shown by the studies of Kammerer, if the exclusion is absolute future trouble can be expected.

Resection of the cecum was first performed by Billroth in 1876, and the operation has now been done many times and a large number of cases have been reported. The operative mortality as given by Grieg Smith was between 30 and 40 per cent. Furnival estimates the mortality of the more recent cases as somewhat less, 20 to 25 per cent., perhaps. Butlin, in 95 reported cases involving the cecum and ascending colon, gives an operative mortality of 29 from shock and sepsis, and 66 recoveries.

Excision of the cecum for malignant disease usually requires removal of the ileocecal juncture and if the disease be not too advanced can be readily effected. The arteries are almost all terminal with but few anastomotic loops (Witherspoon) and the ligation of the blood supply does not endanger contiguous portions of the bowel. A lateral incision is most convenient. The peritoneum along the outer wall of the cecum and ascending colon is divided, the malignant portion of the bowel raised and the vessels ligated. The ascending colon is cut across, one and one-half to two inches above the upper limits of the disease, and its distal end turned in by a purse-string suture. The proximal portion, clamped to prevent leakage, is lifted out of the abdomen and when completely separated from its other attachments, the ileum is divided at a healthy point. The anastomosis is best effected, end of the ileum to the side of the ascending colon. If the ileum can not be readily brought to this portion of the colon, it can be attached to the transverse colon either end to side or side to side.

The ultimate results of excision done early are good. Van Bramann in 14 cases had 4 free of recurrence after three years, Macewen two out of five, Wolfler two out of twelve, Czerny three out of eighteen cases. When it is considered that a number of the remaining cases were free from recurrence although less than three years, it is certain that later reports would increase the percentage of permanent cures. We have excised the cecum four times, twice for malignant disease, once for tuberculosis and once for chronic intussusception, all of the patients recovering from the operation. In the past two years we have met with five cases of cancer of the cecum. In two, extirpation of the ileocecal coil resulted in recovery, in two the extent of the disease prevented a radical operation and ileocolostomy was performed for relief and in one advanced case without obstructive symptoms, the exploratory incision was closed. A brief report of the two cases in which a radical operation was performed is appended.

Case 1.—Carcinoma of the Cecum Involving the Ileocecal Juncture. Extirpation. Recovery.

J. E. R., Yankton, S. D., American, 38 years of age. Admitted to St. Mary's Hospital, Rochester, Minn., April 4, 1899. History of colicky pains in the abdomen for four years. While not severe, the pain has been persistent; during the past year it has become located in the right side. For four months a diarrhea has been persistent and he has lost 40 pounds in weight. Family history negative.

Physical Examination.—A moderately emaciated man of cachectic appearance. No evidences of disease of organs outside of the abdomen. Temperature and pulse normal. There is considerable intestinal distension and intestinal peristalsis waves can be seen and are accompanied by marked gurgling. On deep pressure in the right side an induration can be detected, evidently connected with the cecum. It is about the size of a small lemon, firm to the touch and not very sensitive. Upon the history and physical signs the diagnosis of appendicitis seems warranted and it is thought to be tubercular in origin and the obstruction due to adhesions.

On April 6 a lateral incision revealed a nodular tumor of the cecum involving the appendix and ileocecal juncture. A few enlarged glands could be felt behind the bowel. An incision through the peritoneum was made on the outer side and the cecum with the enlarged glands was lifted out of the abdomen. The vessels supplying the part were ligated with catgut. The ascending colon was divided two and one-half inches from the tumor and its distal end closed with a circular suture. The proximal end was clamped. The mesentery was progressively ligated and the ileum divided eight inches above the ileocecal valve. An attempt was made to join the end of the ileum to the side of the ascending colon but there was some tension, the divided end was therefore turned in with a circular suture. The omentum was raised and the side of the ileum six inches above its severed extremity was anastomosed to the transverse colon near the hepatic flexure with a Murphy button. A small drain was introduced into the right side and the incision closed. Recovery was uneventful. The patient was discharged May 3, 1899. He rapidly regained his usual weight and strength and is now pursuing his work in better health than for years before. Microscopic examination showed only inflammatory changes.

Case 2.—Carcinoma of the Cecum, Involving the Ileocecal Juncture. Extirpation. Recovery.

A. C. S., Maiden Rock, Wis., Scandinavian, 30 years of age. By occupation a fisherman on the Mississippi river. Admitted to St. Mary's Hospital, Jan. 6, 1901, with the following history:

For the past six months has suffered from cramps in the abdomen with a feeling of weakness. For the last three months the pain has been nearly constant in the right side, losing weight and strength, constipated. Family history good.

Physical Examination.—A man of good physique, somewhat emaciated, walks with the right thigh drawn up to relax the psoas and iliacus muscles. Temperature and pulse normal. No evidences of disease outside the abdomen. There is some tympanites. On deep pressure in the right side a small mass can be detected which is tender to the touch. A diagnosis of chronic appendicitis was made.

January 8, an intermuscular incision (McBurney) was made and a tumor involving the cecum, appendix and lower ileum was exposed. The incision was lengthened, cross cutting the deeper muscles. The peritoneum was divided outside and the cecum, appendix, ascending colon and fourteen inches of the ileum was excised, a lateral anastomosis between the lower ileum and transverse colon being effected. There was extensive adhesion posteriorly in the mesentery necessitating the extensive resection. A few small glands were found. A small drain was introduced and the incision closed. Patient discharged February 27 in good condition. The microscopic examination of the glands removed showed only inflammatory changes.

In conclusion, I would urge that every operating surgeon be prepared to excise the cecum. The early symptom may be such as to lead to the belief that an appendicitis exists and in this way a timely operation for a malignant process may result in a complete cure.

DISCUSSION IN SYMPOSIUM ON THE SURGICAL ASPECT OF CARCINOMA.*

Dr. A. C. Bernays, St. Louis—From what has been shown here we are to face an endemic of cancer. The exact figures, as Dr. Dennis read them, I do not remember, but there is undoubtedly now an endemic of cancer which we have recognized, because it has increased largely in recent years. This endemic seems to affect all classes. The question is: Will it be possible by united, collective effort to bring help, as we have done in other diseases, which we have attacked collectively in our professional efforts? Dare we hope for a curative remedy? I think not. Let us be modest. We dare to believe that by collective investigation, such as we have made in other pathologic conditions, we may gain accurate knowledge regarding the location, frequency and geographical distribution of cancer, also its mortality and length of life of patients afflicted. Upon that basis we dare hope that we may be able to exercise a sort of prophylaxis, as we now do in tuberculosis; we may confidently expect this much. But even this result will depend largely upon the success of our efforts in discovering the nature of cancer. Many men have worked upon this question. All have failed to solve the problem. I believe that only a few cases will furnish material which will be useful in our research for the parasite. I believe that not all cases of what we call cancer now—and I wish to emphasize that point here—are due to parasitic infection; some cases are undoubtedly degenerative processes, necrobiotic processes of tumors or growths developed on the basis of rudimentary tissues which we have inherited from an infinitely long line of ancestral forms of life. What we call cancer, or what we call malignant disease, consists of many different things, and the investigations, which I think will be pressed and enthusiastically continued, will show that under the head of "cancer" some quite different things are included; some undoubtedly of parasitic nature and others of embryonal or rudimentary and developmental nature. If the discoveries and conclusions of the New York investigators, under the direction of Dr. Park, are based on careful observations, they will soon be corroborated by the researches in laboratories all over the planet.

A few words on resection of the cecum. About two months ago I had an opportunity to resect a cecum in a case of cancer. I will relate it as briefly as I can, and then make a sketch of the operation. The patient was a man aged 54, who had been sent to me for operation by a good physician, with the diagnosis of chronic appendicitis. I felt a hard nodule in the right iliac fossa, but was unable positively to make a diagnosis of chronic appendicitis; nor was I able to come to the positive conclusion that there was a cancer of the caput coli, or ileo-cecal valve, as it proved to be. Deciding to operate, I opened the abdomen and found a large lump, consisting of glands; the meso-colon and the mesentery were normal. There were only a few small glands. I used the Kocher clamp and clamped off the gut and the ileum by clamping at right angles. By closing it tightly I was enabled to cut away this whole mass, and, putting my hand under it, to lift it up from the iliac "shovel." This was accomplished with scarcely any bleeding, perhaps a little from the surface from which I lifted up the mass. There was only one large artery coming down, which was tied. The ileum fortunately had a long mesentery and it was freely movable and the colon also could be turned well out of the wound. I intended to close up this hole by simply inverting the whole thickness of the bowel and closing it with a few catgut sutures, but, at that moment, it struck me that the better plan would be the Maunsell operation, inasmuch as I had here a large hole in the cecum. So I introduced a pair of forceps, bringing this piece of gut up; at this point I made an incision in the cecum, and by means of a pair of forceps brought this piece of gut together with the cecum. I was then enabled, in the very simplest manner, to sew together, just as Dr. Weir did in the resection of the rectum; I sewed the gut into the cecum by through-and-through sutures, then simply drew it out, and then put on some Lembert sutures on the outside all around, and finally closed this opening here with Lembert stitches. That finished the operation. I think you will have to admit that that method is simpler than any other method, and restores almost to the normal condition after the resection of the cecum.

---

* Papers by Drs. Park and Powers published Sept. 14, 1901; Drs. Weir and Senn, Sept. 28, 1901.

Dr. G. W. Crile, Cleveland—I wish to briefly describe a method of controlling hemorrhage in operations for malignant disease of the tongue. A small screw clamp with parallel blades, protected by small pieces of rubber tubing, may be placed upon the common carotid arteries and so adjusted by the screw as to close the lumen of the vessel, thus rendering the field bloodless.

Dr. W. L. Rodman, Philadelphia—I think we are all beginning to feel that there is an accumulating amount of evidence that carcinoma is due to parasitic disease. Certain things indicate that it is due to a parasite. The very fact of its encroachment would indicate that it could not be anything but a germ. We know that carcinoma, until recently, was not a disease frequently found among the Indians and negroes, and yet, at the present time, it is practically found in both races; carcinoma of the breast in the negro is probably more common than in the white. This change must be due to a germ, and, once having started, it is likely to continue and increase. Dr. Dennis raised a very important question when he said that he had not seen a case of sarcoma of the jaw recover. In a discussion not long since, in the Philadelphia County Society, rather the opposite position was taken with regard to sarcoma of the jaw. It was held that an operation that is radical and done early is more likely to prove successful than sarcoma in any other part of the body; a very good reason was given for it at that time, viz., the fact that the mouth is a septic cavity and that suppuration results after an operation. This explains why more cures are reported on the upper and lower jaws than sarcoma in other parts of the body. I know of a case of sarcoma of the lower jaw fourteen years after operation and the upper jaw two years after operation. I fully agree with the position taken by Dr. Powers that we should cut into a tumor for diagnostic purposes; it is not only justifiable, but the best course that one can take. The little risk incurred in doing this is more than justified by the fact that it is hardly fair needlessly to remove the mammary gland of a child-bearing woman.

Dr. Gustav Fütterer, Chicago—While I do not intend to discourage research in that direction, I wish to state that I have never been able to believe that parasites are or may be the cause of carcinoma. Probably the strongest reason against a parasitic cause lies in the fact that in carcinomatous metastasis the cells of the organ invaded do not become infected, and do not participate in the building up of the metastasis, which develops from the invading cells. I have first advanced this reason at a meeting of the Chicago Pathological Society, Dec. 14, 1896, and I still consider this fact of the highest importance; it is hard to conceive that such would be the case if the invading cells included parasites.

I have always adhered to Virchow's theory of irritation, and after all that I have seen, I take a firmer stand on this than ever. Friction causes no real inherent malignancy of the epithelial cells, but only an apparent malignancy. It is none other than can be explained by a greater supply of blood that is not regulated with even nearly the almost mathematical correctness which governs the nutrition of the epithelial apparatus under normal conditions. So while I do not believe in an inherent malignancy of carcinoma cells, I do believe that normal epithelial cells, through continued circulatory disturbances, become trained to indure and prosper by a condition of hypernutrition. Hand in hand with sprouting blood vessels surrounding them, the epithelial cells may invade the deeper tissues, the resistance of which has either been lessened by chronic circulatory disturbances, particularly edema, or by a reduction of the volume of blood in old age. Then they may proliferate in the deeper tissues making metastasis and causing cachexia. It may be cachexia of a different kind, as the cells retain their physiologic function more or less, according to local conditions, overloading the circulation with physiologic products. This alone will explain the different forms of cachexia, such as we find them, for instance, with carcinoma of the stomach, primary carcinoma of the liver, etc.

Dr. G. B. Massey, Philadelphia—The last remark made by the speaker seems to me to be capable of being answered by objections against the autocytic theory, which would be evident to the biologist. For to adopt the autocytic theory of cancer we must assume that cells can change their character. We must assume that cells that have been generated as tissue cells, with a benign course or history, can suddenly, for some unknown reason, entirely change their character. No one can watch these growths for any length of time without feeling sure that there is a separate entity in that growth from the entity in the host, that there is an entity there, a separate entity, totally distinct from the man or woman on which it feeds. I wish simply to make the point that the very evident parasitic nature of cancer should attract more attention from the profession to an antiparasitic method which was brought to the attention of the Section on Practice of Medicine of this Association, at its meeting in 1897, by myself. That is a method by which the electric current is used to cause a chemical disintegration of a growth at once under ether, together with the production of a surrounding zone of sterilization; it produces a zone from an inch and a half to two inches in extent beyond where all tissues are destroyed and beyond where the demarcation commences. In this zone the physician may feel assured that a large proportion, if not all of the germs—by improved technic—may be killed without destruction of the normal tissue cells. This method has been tried in my hands in 42 cases, and I maintain that it is time for one or two other men also to try it. These 42 cases were brought mostly by physicians, most of them having been previously operated on by the knife, 23 of them died of metastases in spite of what I did, the metastases originating prior to the application. Nevertheless, 15 out of the 42 cases are living, and the great bulk of the 15 cures are of more than two years' standing; in several 7 years have elapsed since the application, and in others 5 years, without recurrence.

Dr. R. H. M. Dawbarn, New York—I desire to express my cordial approval of Dr. Bloodgood's advice in favor of the most radical insistence upon extirpation of all tumors, all lumps in the breast of whatever kind. In a great many instances our patients will veto the suggestion, but that does not prevent our duty of proper advice in the case. I have been making a special study of malignant work, especially about the mouth, the regions supplied with blood by the external carotid, and next autumn I shall publish a list of about forty personal operations of that nature. Regarding the operation for cancer of the tongue: 1. The chief cause of death is shock. One chief cause of shock, as we all know, is hemorrhage. There is nothing I am more certain of—differing from Dr. Christian Fenger in this regard—than the wisdom of ligating the external carotid in every case, prior to a complete extirpation of one-half or of the whole tongue. This ligation can be done in five minutes; and, thanks to the early work of Dr. Wyeth, we now know that it is done with great safety; it makes the work done subsequently practically bloodless. We do not, then, need to do a preliminary tracheotomy. 2. If the patient does not die then, but later, what will the cause be generally? It will be sepsis, particularly that of a pneumonic nature, and due to entry of septic discharges from the mouth into the air passages. Apropos of that, I think it is wise to rub the raw surfaces in the mouth with aristol at once. If we adopt that plan, we will have surfaces that will not offensively slough. I do not pack the floor of the mouth with gauze; instead of packing, I use very frequent irrigation with a fountain syringe. We all know that a considerable percentage of cases of tongue excision die of sepsis. I have lost several myself in my early work from septic pneumonia; these I feel sure that I could now save. The chief cause of death was the position of the patient *post operationem*. In the "International Text-Book of Surgery," in an article on this subject, there is a bit of advice which seems really dangerous; it is that as early as possible patients from whom the tongue has been excised shall be allowed to sit up. On the contrary, I know that they should always be put with the head lower than the foot of the bed, and kept there so long as there is a sloughing condition of the mouth, lest the foul saliva gravitating down the air-passages cause a "schluct-pneumonie." When there is a healthy, odorless, granulation surface, and when control of the stump of the tongue in the act of swallowing is regained, so that coughing does not show that food or drink is passing "the wrong way," then, and not before, it is wise to let the patient's head be elevated—even though this require weeks or longer. In conclusion, let me allude to a point heretofore neglected by operators, but as I believe unwisely. When just a little of the base of the tongue can safely be left attached to the hyoid bone, it is most important that this stump gain power to resume its function of closing down the epiglottis over the larynx in the act of deglutition. I do not know of any text-book that advises what I have practiced, namely, to save the long stump of the healthy twelfth (hypoglossal) nerve, making a little slit in the remainder of the intrinsic muscle of the tongue and sewing with fine catgut into this cut the end of the twelfth nerve—so that this motor nerve may, in time, control the muscle. I have felt encouraged to continue this point in the technic of the operation.

Dr. A. H. Levings, Milwaukee—I desire to call attention to one of the conclusions made in the classic paper by Dr. Senn, namely, regarding the development of carcinoma from epithelial cells. It was stated that all carcinomatous growths were the result of an atypical proliferation of epithelial cells from a matrix of embryonic cells, of congenital or post-natal origin. In the discussion, I desire to call attention very briefly to the histology and embryology of the enamel organ of the teeth. The enamel of the tooth is epiblastic in origin and comes from the epithelial structures lining the mucous membrane of the mouth. If we consider the embryology we find that at about the end of the second month of fetal life a proliferation of the epithelial cells in the form of a half circle and situated directly over the maxillary bones takes place. This growth of epithelial cells dips down as a solid wall into the deeper tissues beneath, or into the mesoblast. From this wall numerous pillars are given off, one for each of the deciduous and permanent teeth. The ends of these pillars become bulbous, forming the enamel of the teeth and enclosing the papillæ. During the fourth or fifth month of fetal life the tooth follicle, made up of connective tissue, encloses the enamel, cutting it off from the above-mentioned pillar. We have then within the mesoblast not only a solid wall of epithelial, embryonal cells skirting the entire area of the jaw, but also some twenty-six columns of cells given off from this wall and projecting into the still deeper tissue. This entire mass of embryonal cells has no further function and is either in part absorbed, or remains dormant and sequestered within the tissue as functionless cell nests. There is no other portion of the body in which there are anything like the same number of dormant, useless, embryonal cells sequestered within the tissues, as occurs within the jaws. It is a well-known fact that epithelial tumors, either cystic or solid, taking origin from these sequestered cells are among the rarest of pathologic curiosities. Up to the present time probably less than a half dozen, and as far as I am aware, but four have been reported. It would be a curious fact were the Remak-Cohnheim theory of the production of tumors correct in all cases, that here in the jaws where these embryonal, sequestered cells are so abundant that epithelial tumors are so infrequent. In so far as my investigation extends I am unable to satisfy myself that the Remak-Cohnheim theory of the causation of tumors is applicable to more than a small proportion of the whole.

Dr. K. A. J. Mackenzie, Portland, Oregon—The weight of evidence from the standpoint of the investigator is strongly in favor of the parasitic theory and this evidence is very strongly enforced by the clinical facts. The concurrent testimony of other investigators in foreign countries who have followed up this line of research is very significant, and the recent work of Leopold, Plimmer, and others affords apparent corroboration of the present work of Park and Gaylord. In considering the clinical evidence one is impressed with the frequency with which the disease develops in regions where there are departures from the normal, anatomic, and physiologic standards. Witness the frequency, for instance, with which the disease develops in such exposed points as the lip, tongue, breast, penis, angle of the eye, skin, chronic ulcers and cicatrices, etc., these facts being very strongly suggestive of an infection introduced from without and not acting from within the body. Within the body we find a strong analogy when we consider that the disease develops at points where the local conditions favor first irritation and subsequently infection. The pylorus, the stomach, the hepatic and splenic flexures, the rectum, the gall tracts, the pancreas, the bladder, etc., all bearing testimony to the topical tendencies of this disease and to an infective process. So apparent is the fact that the inference is just, that the development of carcinoma always predicates, 1, a departure from the anatomic or physiologic standards of the parts and 2, an infection. By parity of reasoning the hope of successful treatment must largely rest in prevention, in the early recognition of all disordered physiologic and anatomic states and their timely correction.

Dr. C. A. Powers, Denver—Dr. Bloodgood spoke of the relative frequency of breast tumors at the Johns Hopkins Hospital, giving, as I remember, a proportion of 426 cases out of 12,000 admissions, or over 3 per cent. of all admissions to the hospital. Possibly such a high ratio may be explained by the fact that the work done there on the breast has attracted to that clinic an unusually large number of breast cases. I think 3 per cent. would be much too high for us to expect as an average. Dr. Weir's operation for cancer of the rectum seems to be an admirable one; thorough, permitting an excellent inspection of the parts, with good control of hemorrhage, and offering a better chance of cure than the Kraske operation. Kraske himself says that most cases of carcinoma of the rectum have a high seat. I fail to understand from Dr. Weir whether the upper fragment comes down easily. In the Kraske operation we find a great deal of difficulty in bringing down the distal end of the upper fragment. It has been my fortune to do five Kraskes, and I look upon it, as we all must, as a dangerous operation. I think it one of the severe operations in surgery; certainly in the hands of the best operators it has a mortality of not less than 20 or 25 per cent.

Dr. W. J. Mayo, Rochester, Minn., in closing—My object in preparing this paper was not to present anything new. The frequency with which operations for appendicitis are now being done, and the evidences that would induce us to operate on cases of appendicitis will lead to many early operations for carcinoma of the cecum, and we should be prepared for that. The two cases in which I succeeded—I believe in securing ultimately successful results—were both induced by a diagnosis of appendicitis. All who operate with that diagnosis ought to prepare themselves for excision of the cecum.

The Blind as Masseurs.—E. Eggebrecht of Leipsic has trained four blind women and nine blind men in the science of massage, and describes his methods and the technique in the *Ztft. f. Diät. u. Phys. Therapie*, V, 2. He believes that it is the duty of physicians to encourage this employment for the blind, not on account of pity for their misfortune, but because they are so exceptionally endowed for it by the development of their sense of touch. A writer in the *Wiener Klin. Woch.* states that the majority of physicians in Austria entirely disapprove of massage by the laity, and consider it incumbent on them to refer patients for massage to young colleagues just entering practice and waiting for clients.

ON THE GROWTH OF EPITHELIUM.*

LEO LOEB, M.D.
CHICAGO.

In the following I intend to report upon some experiments which were undertaken as a continuation of former work published in 1898, in the *Archiv f. Entwickelungsmechanik.* There are reported observations on the growth of epithelium in the coagulated blood during the healing of wounds. I found that epithelium may branch in the blood. I further gave pictures of epithelium surrounding connective tissue structures and even small particles of cartilage. As observed before, mitoses were found in the deepest rows of the epithelium, but besides these I found pictures which could only be explained as amitoses. These were usually situated in the upper rows of the epithelium. The furrows in the nuclei went so far that an entire separation of the different parts of the nuclei could be observed. Without going into the former literature, which was given in my former publication, there appeared since 1898 three papers on this subject, namely, the papers of Kromayer, Branca and Von Bardeleben.

My further investigations were undertaken: 1. To determine the situation of the blood in the growing epithelium. 2. To exclude the possibility that the blood only secondarily raised the epithelium and separated its different parts. 3. To find a means to bring about such separation of the growing epithelium from the underlying connective tissue in an experimental way, so that we might not need to rely upon accidental observations. An occasional observation was made once before by Garré, who saw that in a transplanted piece of skin a few cells were pushed down into the blood, but he did not observe any extended growth of branching epithelium into the blood. 4. To find out in a general way how frequently it was possible to separate growing epithelium from other growing tissues.

My results are the following: If epithelium penetrates into the blood it surrounds small particles of blood and includes it. We then find single blood corpuscles either included inside the epithelial cell, at the side of the neucleus, or we find them between the epithelial cells in small cavities, surrounded by a distinct membrane. Near such places we may occasionally find mitoses of epithelial cells and pictures which speak in favor of amitotic division.

We also find a larger collection of red blood corpuscles inside the epithelium. Blood corpuscles inside the epithelium did not cause the epithelial cells to become pigmented.

To bring about, if possible, a separation of the growing epithelium from the growing connective tissues, I used the following procedure: A small flap of skin was raised in the ear of the animal; at the point of insertion of the flap a second flap with the cartilage and the deeper structures were cut out with a razor and a piece of agar introduced under the cartilage. Then the skin was placed directly over the agar and the cartilage above the whole was fixed with collodium. Under these conditions a variable quantity of leucocytes is found in the agar and the surrounding tissues. The effect of softening the agar and surrounding tissues by the leucocytes makes it easy for the growing epithelium to penetrate agar and tissues.

We thus find frequently the epithelium growing directly into the agar. Not only the deepest layers of the epithelium invade the agar, but also the upper rows of the regenerating cells may grow upwards into it. New branches are frequently given off. Even single rows of cells may branch into different directions. The epithelial cells under these conditions frequently become spindle shaped.

At other places we find particles of agar surrounded by growing epithelium. Sometimes there are very few leucocytes near or inside the agar; sometimes there are a larger number present. We frequently can observe that the epithelium is not accompanied during its growth into agar by a continuous layer of growing connective tissue. One may perhaps occasionally see besides leucocytes a few cells which might be of connective tissue origin, but at other places we see the epithelium distinctly not accompanied by connective tissue. We may find mitoses in cells directly resting on agar, or inside of a mass of epithelial cells, surrounded by agar; epithelium growing into agar did not usually produce any keratohyalin, nor was there a regular formation of the horny layer. I found that with a few exceptions the epithelium began to undergo these normal changes (the formation of typical keratohyalin and of a horny layer) only after it was again in connection with well-developed connective tissue. The newformed keratin separated the agar and epithelial cells in it from the underlying tissue and the agar was thrown off after a short time. The epithelial nuclei could for some time still be seen as dark rods, situated in filaments which were the remains of the epithelial cells. Occasionally we found in epithelium situated in the agar the beginning of the formation of an epithelial pearl. Under such abnormal conditions I also saw in epithelium which had grown between agar for a longer period and which, therefore, was accompanied by connective tissue, a body very much resembling the cell inclusions seen in carcinomatous cells and by some believed to be parasites.

I found pictures of epithelium beginning to grow into the muscle tissue. The cells which are very much elongated surround the muscle fibers. The conditions necessary for that are probably the same as given above in regard to agar, namely, that there has been previously a dissolving action by leucocytes, although these latter may afterwards absolutely disappear and the epithelial cells alone may then surround the muscle fibers or the parts of cartilage. It is impossible at present to state how much the epithelial cells are aiding this process started by the leucocytes. It is also impossible at present to give with certainty an analysis of the different factors which might come into play during the growth of epithelium, which make the epithelium branch in different directions in the blood or in the agar.

Another and perhaps more satisfactory method for extending experimental studies on different tissues, which may give us the means to investigate their growth under variable external conditions, is the following: A piece of the tissue, in this case of epithelium of the skin, is entirely cut off with a razor and pushed into coagulated blood serum as it is used for bacteriological purposes. The blood serum with the included epithelium is transferred afterwards into a living animal.* After 7 or 10 days we may find that at many places the epithelium has grown inside the blood serum; rows of cells grew into different directions, epithelial cells surround particles of the blood serum, cells branched off and extended further into the culture medium. Frequently individual epithelial cells included some of the blood serum in vacuoles situated near the nucleus. The periphery of such cells showed repeatedly a distinct radiating striation. Occasionally such cells became even detached from the main mass of cells, they assumed a round shape, but showed even then the characteristic striation and included the blood serum near their nucleus.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association in the Section on Pathology and Bacteriology, and approved for publication by the Executive Committee: Drs. A. Stengel, W. S. Hall and L. Hektoen.

* Certain necessary precautions will be described in another paper.

There were almost no leucocytes visible at this period and over considerable areas the epithelium was not accompanied by connective tissue. Nevertheless, several mitoses could be seen in the epithelium and always in cells directly in contact or near the blood serum, just as in the ordinary epithelium the mitoses are found near the connective tissue.

The cells and nuclei were usually drawn out as if traction had taken place on the protoplasm of many cells. The cells were not massed together as it would have been expected in case the mitotic division and the pressure resulting from the increased number of cells were the only cause of the ingrowth of the epithelium. It is therefore probable that there are other protoplasmic movements at play besides that connected with the mitotic division of the cells.

In conclusion, it might be stated that during its growth the epithelium forms a mass of cells, all layers of which are equally able to grow in different directions. A distinct differentiation between different rows of these cell masses does not exist. Later on the epithelium which comes into contact with connective tissue well supplied with blood vessels forms again regular epithelium, the lowest rows producing new cells, which now undergo the changes leading to the formation of normal keratohyalin and keratin. We see that these growing cell masses do not need connections with either resting or growing connective tissue; although under the usual conditions found during the growth of epithelium, the epithelial cells are found accompanied by connective tissue. The possibility of separating the growing epithelium from other tissues might be used to subject an isolated tissue like epithelium to certain experimental conditions, as for instance, to the influence of different chemical substances and thus study the reaction of isolated tissues, other than connective tissue and leucocytes to different stimuli.

SOME CONSIDERATIONS REGARDING THE HYGIENE OF EARLY SCHOOL LIFE.*

JULIUS NOER, M.D.
STOUGHTON, WIS.

The medical man's point of view regarding the hygiene and physical regimen of school life often gives rise to misunderstanding and not infrequently to the most unreasonable opposition from the pedagogue. The physician, says the pedagogue, is too materialistic, is too much occupied with the pathologic side of the child and not infrequently is biased, catering to the hysteric dilettante for the mere sake of humoring the misguided parents.

Under the head of "Mental Fatigue in School"[1] appears, among other propositions of a similar character, the following translation, from a paper by Prof. Albert Spitzner, Leipzig:

"The propositions generally advanced, that present methods of public education imperil the health of children, is not only applied to certain evils for which individual teachers or schools are called to account, but directly attack the normal foundation of a school. The censure of physicians does not refer to the harming of already sick or nervously inclined pupils, but to injury done to mentally and physically normal children, by methods and practices considered normal." Dr. Pellmann, tersely expressing himself, says, "Children work too soon, too much and badly; that is to say, under unfavorable hygienic conditions." In interpreting his meaning we are reminded of the long list of studies, the rushing through of courses, the long duration of hourly, daily, and weekly lessons of useless studies, the method of teaching, unscientific in its disregard of the laws of physiology and purely in favor of psychology, the evil of home tasks which rob children of their short periods of recreation, etc. We receive also the practical suggestion of omitting home lessons, instructing by means of observation lessons, instituting a beneficial interchange of physical and mental occupation, etc.

Further on the paper continues: "It may be truthfully said that the judgment of the medical profession on these matters is not based on an actual, exact, and technical examination of the methods employed, but on inference from facts connected with nervous diseases of children." Psychologic pedagogy must protest against such arguments.

Again, this same report says: "In view of what has been said, the doctrinary foundation upon which the medical profession bases its opinion of psychic and in part physiologic conditions and processes, can not be accepted by teachers who must protect their profession against medicine and its encroachments; that is to say, must place psychologic pathology and pedagogic hygiene and therapeutics in so clear a light that the facts connected with the intellect and the development of children be studied in a manner consistent with their real meaning and pedagogical observation."

This represents briefly the case of the routine pedagogue versus the physician, as regards the school curriculum and its influence upon the development of the child. We may, by reason of our purely materialistic tendencies, have some difficulty in grasping the exact meaning of pedagogic therapeutics and hygiene, as well as psychologic pathology, but otherwise there is certainly no ambiguity in stating the case.

It is perhaps true that the physician is often too radical, and that occasionally when in doubt, liable to err on the side of physical well being. Occasionally he may also be guilty of humoring the wishes of an hysterical parent. Errors of this sort are a necessary concomitant of the imperfections and shortcomings of human reason and human nature. When, however, we study the basis of such criticisms as have been offered by Hasse, Pellmann ,Nathan Oppenheim, Francis Warner, Bowditch, J. M. Rice and others, whose reasons are not based upon inference, but upon the data—possiblyyet too meager—furnished by physiologic and anthropometric observations. From data already at our disposal, it is clearly evident, 1, that mental and physical abnormalities exist in school children and, 2, that these abnormalities are always aggravated, if indeed they are not actually produced by pedantic, pseudo-educational methods.

As a matter of fact, the physician's capability and wisdom in educational matters has always been acknowledged in the most difficult department of education, that of the mentally and physically defective, i. e., idiots, imbeciles, the feeble-minded and the defective classes. When, indeed, reason becomes deranged he is called upon to restore it to its normal balance, which he often succeeds in doing, not by the administration of medicine, but by the adaptation of wise training and the judicious application of the laws of physical and mental hygiene. It appears, therefore, eminently proper for the physician to interfere in matters relating to school hygiene, even though this may involve the criticism of the curriculum and also some of the more absurd conclusions of psychologic pedagogy.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee of the Section: Drs. H. E. Tuley, Edwin Rosenthal and Samuel W. Kelley.

[1] Report of Commissioner of Education, 1895-6, p. 1191.

Very briefly and imperfectly epitomized, the general import of the medical protests against the prevailing public educational methods may be summarized as follows:

1. We insist that there is no evidence by which educational values can be determined, except through the study of material manifestations transmitted through the nervous system. Thought and mind are immaterial, but we have no way of measuring, or estimating the value or extent of their action, except through the evidences of material production. For this reason we are forced to study the physical and physiologic changes produced in the body as the result of psychologic activity.

2. Education produces nothing new in the child: it simply unfolds and brings into intelligible activity the latent forces of the nervous system. Most of us agree with Prof. H. H. Donaldson,[2] who says, "Education consists in the modification of the central nervous system."

3. One of the most important and essential prerequisites necessary for a good education is good nutrition. Psychologically, mind is immaterial, but physiologically, we are forced to the conclusion that sane thought and vigorous intellectual activity is possible only through the medium of brain cells that are well nourished and physiologically active. It appears, therefore, entirely reasonable and logical to conclude that all educational methods which ignore the physiologic evolution of the child, are faulty and open to criticism, from the physiologic and hygienic standpoint. As a matter of fact, we not only ignore the most obvious requirement of practical hygiene in our school curriculum, but we insist upon a uniformity of educational training which is physiologically as absurd as it is impossible of practical application. "In fact," says Dr. Nathan Oppenheim,[3] "I know of no harder experience, no more trying ordeals than what a child at this time undergoes. His experiences in the school environment are designed to encourage irritation and waste of nerve and muscle tissue; the circumstance of instruction are useful for deadening, instead of encouraging, a normal standard of intellectual development."

When we consider how variable is the inherent mental capacity of children, in fact so variable and so difficult to determine that we find it almost impossible to draw a line of demarcation between the normal and the abnormal child; when we consider that this constant variability to respond to educational stimuli, so manifest at all the different stages of development, it becomes evidently absurd to attempt to lay out a uniform system of mental training applicable to all alike, exclusive of pronounced idiots and imbeciles. That this method does injury to a great many children is not only the testimony of physicians, but also of a great many progressive educators and thinkers as well.

Regarding the influence of school life upon normal, healthy children, Dr. Francis Warner, London, says: "I do not think that the boy or girl at the older ages of school life, who is free from developmental defects of any kind and shows no abnormal nerve signs or indications of delicacy, i. e., the normal child, is very likely to fall into ill health or a nervous condition if a wisely conducted training at school is continued. Of the 100,000 children that I have examined at schools, 80 per cent. of the boys and 84.10 per cent. of the girls were normal and not reported as dull mentally. It is, however, far otherwise with the children who have some defect; anemia, nervous disturbances or hysteria may become manifest as adolescence approaches, especially in girls. When such becomes established, particularly if anemia and nerve disturbance occur together, a long period of ill health may result."[4]

His table of statistics shows, of all cases with developmental defects at all ages, 38.4 per cent. of the girls, and 49.9 per cent. of the boys were mentally dull. Of all dull children, at all ages, 57.6 per cent. boys and 52.6 per cent. girls also presented abnormal nerve signs. This appears to indicate that about 18 per cent. of the children examined have some developmental defect, and that of these defectives 44 per cent. are mentally dull.

It is impossible, by reason of insufficient data, to form a reasonable, accurate estimate of the existing number of defective children which imperatively demand special school training. In Germany and England, where special classes are maintained for defective children, they average about 1 per cent. of the school population. Dr. Charles F. Folsom[5] gives the number of pronounced intellectual idiots and imbeciles as 1 to 650 of population. That we have in our public schools a very large percentage of mentally abnormal and physically defective children who require segregation and special training is evident from the physiologic and anthropometric examinations made in many of our cities.

I have briefly referred to this subject of the dull, the backward and the defective child, to emphasize the practical value of regular, periodic, physiologic examination of school children. Such examinations would disclose incipient cases, classified by teachers as dull, stupid, backward, disorderly or incorrigible, when in reality the child is the subject of some developmental abnormality, which makes ordinary school work intolerable to him. The early discovery of these cases and their segregation for special training is one of the important problems of public school life. Pupils of this character are a drag and a danger to the normal child. I am fully aware of the practical difficulties to be met in a solution of this question; but that these are not insurmountable has been shown by the experience in some of the European countries.

The study of the defective, i. e., the idiot, the feeble-minded, and persons afflicted with sensory aphasia resulting from an injury to the central sensory nerve cells, has made it possible for us to understand in a measure how ideas are built up during the developmental period. The fact that these observations are based upon changes that may be termed pathologic does not diminish their practical value.

[3] Development of the Child.

[4] "The Study of Children," Francis Warner, MacMillan & Co., p. 190.

[5] Pepper: System of Med., vol. v, p. 140.

The mentally defective represents arrested brain nutrition, partial or total, at an early period of development. It was early shown by Dr. Sequin and others that a partial restoration of the dormant nerve cells of the idiotic brain could be effected by the application of judicious training along the lines of primitive development. The recognition of this principle has done wonders for the idiot, so that he has not only been improved, but even educated and cured. These well-known facts are referred to because they clearly indicate that the early school training of the child is largely a problem of localization of stimuli at different points in the nerve centers. This stimulation, if it is not prolonged to such an extent as to produce fatigue, promotes nutrition and tends to the reproduction of the action after a period of rest.

That we have vastly overrated the intellectual value of this formal training to the child there can be no doubt. That we have carried it to unreasonable extremes and burdened it with artificial, psychologic, and other incomprehensible nonsense is undeniable.

Returning again to the normal child, it is a mere truism, often enough reiterated, to state that our schools should have the benefit of good hygiene, good light. proper heating, ventilation and seating. Regarding these matters there is general agreement so that improvements in these departments are simply a matter of financial and mechanical detail. When, however, we come to the more vital and difficult problem of the school curriculum and the general methods of training to be adopted in early school life, viz., the number of hours that should be given each day to purely mental tasks, and the age at which school life should begin, there is very general disagreement between the physician and the routine pedagogue.

When we insist upon the fact that well-known physiologic studies show that the child is an exceedingly immature and delicate animal, undergoing important developmental changes having no analogoues in the adult; that his plastic tissues and delicate nerve cells are easily warped and injured by long-continued mental or physical efforts; when we report that children have actually been injured by injudicious school work, and that for this and other reasons, we favor shorter hours, more attention to the physical side of the child, more nature study out of doors in contact with actual natural objects, less of text-books and less of the exhaustive rote drill, which simply burdens the memory; when we insist upon these things as a natural outcome of the observations of the laws of development, we are told that these are questions of psychologic pedagogy, which must be settled by the pedagogues themselves. While it is true that the practical details must be left to the teachers, it does not follow that they are to control absolutely the principles upon which we desire to have our children educated. This would be equivalent to saying that we, as physicians, should have absolute control over the treatment of our patients, irrespective of the consent of the patient and his family. The absurdity of such a proposition is still more apparent when we consider the fact that the pedagogues disagree on both diagnosis and treatment.

As regards the claim that physicians base their criticism upon inference, it can be very easily shown that this is not the fact. As an illustration, I submit the following case:

O. N. is aged nearly 10 years, at the opening of school, September, 1900. Stature, weight and development are normal. There are no physical defects, unless left-handedness can be so called. He has attended public school since 7 years of age. Mental faculties are good, except a little slow to learn to repeat texts from memory. The daily attendance at school from 9 a.m. to 12; and from 1:15 to 4 p.m. At the opening of the school year this boy is in good flesh, with nutrition, sleep, appetite and digestion good, presenting in every way the physical features of a normal, vigorous boy. After some months of school each year he gradually grows thinner, becomes restless, nervous, fidgety and shows dark lines under the eyes. Toward the end of the school year these symptoms increase, the nervousness increases, digestion and nutrition are disturbed. He talks in his sleep, gets out of bed at night, wandering about the room, talking about his examples and his examinations. During the summer vacation, which lasts about three months, the abnormal physical symptoms gradually disappear, physical vigor is restored, the nervousness disappears and sleep becomes quiet and peaceful. This result occurs without medical treatment or change in the environment, except the omission of school work.

Now, is it mere inference when I say that the abnormal physical disturbances in this case are due to the fatigue produced by faulty educational methods? I have at two different periods of three months each taken this boy out of school and placed him under private instruction, with the result that he would accomplish fully as much intellectually in two hours' instruction per day as he did in six hours at school.

That cases of this sort are of common occurrence is well known to every observant practitioner. That injury is done in these cases is undeniable. That these abnormal consequences of pseudo-educational methods can and must be prevented, without detriment or hindrance to the child's intellectual development, is unquestionable.

Granted that our diagnosis is correct, rational preventive treatment would appear to be along lines already indicated, namely, the shortening of hours of the primary school to, say, one hour in the forenoon and one hour in the afternoon. If more time is to be taken up at school, it should be devoted to Slöyd or manual training, together with the study of Nature and natural life and its activities, as it exists in the child's environment.

That this is practically possible, and that the results are exceedingly favorable, has been shown by the experience at Girard College and other similar institutions. The elementary school of the University of Chicago, under Professor John Dewey, is a most excellent demonstration along the same lines.

Regular periodic medical inspection, which should include physiologic and anthropometric examination of the school-children, should be a requirement in all public schools. These examinations would not only furnish valuable physiologic and anthropometric data, but would disclose cases of infections and other communicable diseases. They would also detect mental and physical defects—stigmata—not readily recognized by parents and teachers. These children with marked mental and physical abnormalities, developmental defects, or stigmata, should be segregated for special training. Every town with a school population of from 800 to 1000 will have a sufficient number of children of this sort to fill a room, which should be in charge of a person having the exceptional qualifications necessary for success in this kind of work.

DISCUSSION OF PAPERS IN SYMPOSIUM ON SCHOOL HYGIENE.*

Dr. C. F. Wahrer, Fort Madison, Iowa—The series of papers on backward children showed a difference of opinion as to where the line of demarcation is to be placed between backward and normal children, and again between backward and defective children. In one of the papers appears the suggestion that for these backward children special schools should be maintained. This would be placing upon these unfortunate children a stigma which they do not deserve. To take a child who is pronounced to be backward by a teacher who has not made a special effort to develop the latent mental powers of the child, and place it in such special school seems to me entirely wrong. The best talent of the teacher should be brought to this work of developing the mental powers. A child may be backward only when forced to go in a direction counter to his natural trend, and prove to be a genius when allowed to develop in his proper direction.

Dr. Shelly, of Kansas—It seems that where a child under 10 or 12 years of age in a country school is brought into contact with a child in a city school it is found that the country child surpasses the city child. If anyone else has made this observation I should like to know it.

Dr. Clifton Scott, Des Moines—I do not think that the observation made by the last speaker is correct. I observed in one school that the country boys easily became leaders in their classes but that many of the "town" boys did just as well. It was only the boys from the country who had a special ambition to get a good education, and who were earnest in their work that came to the school, and this in itself would explain the difference, as it is not fair to compare these select few from the country with the city boys as a whole. The reason that Austin Flint was the greatest physiologist in this country was because he had specially good opportunities in early life. Much depends upon these early advantages, though I would not have it understood that I believe in crowding studies upon young children. However, the disadvantages from the loss of good, early opportunities can never be overcome.

Dr. Edwin Rosenthal, Philadelphia—In our city we have a wonderful institution, the Girard College. The plan adopted there is to teach the scholar aged from 6 years upward. Occasionally they meet with children who can not be taught, and all that they have been able to do with these is to make farmers of them.

Dr. James Work, Elkhart, Ind.—We have had papers presented this afternoon from so many different States that it is evident that the subject commands a very general interest. I infer from this that there must be a widespread defect in our school system, or else that we must be a degenerate race. I am of the opinion that the classification in our schools according to intellect is not carried out sufficiently, hence the studies are not well adapted to the individual needs of the pupils. I was much interested in what Dr. Darnall said about the ill effects of closely-fitting clothing, for, I believe it is a factor of considerable importance. In dressing children it is important to secure equal warmth and equal pressure when selecting their clothing. I am satisfied that physicians as a rule are not sufficiently emphatic in impressing upon parents, who have the greatest interest in our schools, the importance of the pupils attending to the organs of elimination. These organs are the bowel, skin, kidneys and lungs. One must expect a child to be dull if it goes to school daily without having had a proper evacuation of the bowel, or if baths are not had two or three times a week. Too, some of us do not understand the first principles of preparing food for children. The great need in most of our schools is that we have trained mothers at home.

Dr. A. W. Wilmarth, Chippewa Falls, Wis.—Mention has been made of the establishment of schools for backward children. Such schools have been already established in Providence and in Philadelphia. It would be well if teachers could give more time to individual pupils, but this is utterly impossible in the present state of our schools. Some provision must be made for these children.

Dr. B. R. Shurly, Detroit—It seems to me that one remedy is to be found in giving medical advice to the school board. Every such board in our larger cities employs legal counsel, yet, so far as I know, medical advice and supervision in our schools are sadly neglected. Along this line we certainly have work to do which will prove of great advantage to children, and particularly to those who are backward.

Dr. W. T. Learned, Fall River, Mass.—I have been interested in this subject since the rearing of my first-born child without his mother. I followed out the plan then in vogue of giving two waters and one milk, but finding that he did not do well I soon increased the proportion until the whole milk was given, and then the improvement was marked. I made the interval three hours, and the quantity that which the child could digest and be hungry by the time of the next feeding. This resulted in natural development. His school work began between the age of 11 and 12, at which time he weighed about 100 pounds. Field work was made a part of his education, and at the age of 18 he weighed 185 pounds. At the age of 21 he entered a university to study law, and passed with honor at the end of one, instead of two years. This picture is presented, not to show that there was anything unusual about the boy, but to emphasize what can be done by an entire freedom from cramming and the maintenance of good health. A moderate amount of brain work and the determination to do something constitute, in my opinion, the best education that we can give our boys and girls. I am totally opposed to the custom of putting a little one of 3 years in a kindergarten and keeping him in school until a diploma is presented as evidence of education. It seems to me that there is no greater defect than that of so drilling and perfecting children in tuition that they can get a living without work.

Dr. J. Noer, Stoughton, Wis.—I wish to emphasize that cases like the one I reported are common. By taking a child out of school and placing him under a private tutor for two hours a day he can accomplish just as much as in six hours at school, while at the same time the nervous symptoms will disappear. I fully concur with Dr. Rosenthal that the method pursued in Girard College is an ideal one. An experiment along the same line is now going on in Chicago, in the Elementary School of the University of Chicago, in charge of Professor John Dewey. It seems to me that this opens up a great field for improvement in the education of young children. I have given this subject considerable attention as a physician and as a member of a school board, and I can not resist the conclusion that there is altogether too much pressure used in conjunction with the early education of the growing child. The physician has a duty to perform in this matter and he ought to use his influence for improvement. He should also be prepared to give an intelligent explanation of the physiologic side of this question to teachers and parents.

Tuberculosis as a Professional Disease.—The French law on industrial accidents is being revised, and one of the amendments proposed urges that tuberculosis be included in the list of professional affections, and that the latter should be regarded as industrial accidents and entail the same responsibility on the proprietor of the establishment. The *Progrès Médical* observes that if this amendment could be adopted the prophylaxis of tuberculosis in large cities would be immeasurably promoted. The victims of professional affections, it states, are more deserving of interest than the victims of industrial accidents, as the latter are frequently due to some imprudence on the part of the workman, while a professional affection is almost invariably the result of the negligence of the proprietor to provide sanitary conditions or to his insisting upon the use of a poisonous substance, because it is cheaper, when a harmless substitute is available. To include tuberculosis among the professional diseases, it adds, and to enforce the penalties, would do more for actual progress than twenty anti-tuberculosis congresses.

---

* Papers by Drs. Baker, Wilmarth, Makuen and Wahrer published Oct. 12, 1901.

THE OFFICIAL REPORT ON THE CASE OF PRESIDENT M'KINLEY.

SURGICAL HISTORY.

President William McKinley was shot, by Leon F. Czolgosz, in the Temple of Music, at the Pan-American Exposition, Buffalo, N. Y., at about 7 minutes past 4 on the afternoon of Friday, September 6, 1901. Two shots were fired. One bullet struck near the upper part of the sternum, and the other in the left hypochondriac region. The President was immediately conveyed to the Emergency Hospital on the Exposition grounds by the motor ambulance, where he arrived at 4:18. Dr. G. McK. Hall and Mr. Edward C. Mann, medical student, of the house staff, were in charge of the ambulance, Medical Student T. F. Ellis being the driver.

On arriving at the hospital, President McKinley was at once placed upon the table in the operating room and undressed. During the removal of his clothing a bullet fell out and was picked up by Mr. Ellis. Dr. Hall placed a temporary antiseptic dressing over the wounds, and Mr. Mann ordered a nurse to administer 0.01 gm. of morphin and 0.002 gm. of strychnin hypodermically.

Dr. Herman Mynter, who had been telephoned from police headquarters to report immediately at the Exposition hospital, was the first surgeon to arrive, at 4:45 o'clock. At that time Drs. P. W. Van Peyma and Joseph Fowler, of Buffalo, and Dr. Edward Wallace Lee, of St. Louis, were present. Dr. Mynter brought with him Dr. Eugene Wasdin, of the United States Marine-Hospital Service.

Dr. Mynter inspected the President's wounds, and immediately saw their serious nature. He told the President that it would be necessary to operate, and at once set about making preparations, aided by the house staff and nurses and Dr. Nelson W. Wilson, Sanitary Officer of the Exposition, who at that time assumed charge of the hospital in the absence of Dr. Roswell Park, the Medical Director of the Exposition. The President's pulse on the arrival of Dr. Mynter was 84; he had no particular pain in the abdomen, and no apparent loss of liver dulness. He was evidently slightly under the influence of the morphin.

Dr. Matthew D. Mann arrived at the hospital at 5:10 p. m., having been telephoned for by Mr. John C. Milburn. He was followed, five minutes later, by Dr. John Parmenter.

An examination was at once made, followed by a short consultation between Drs. Mann, Mynter and Wasdin, which resulted in the decision to operate at once. The necessity for the operation was explained to President McKinley, and he gave his full consent. Immediate operation was decided upon because of the danger of possible continued internal hemorrhage and of the escape of gastric or intestinal contents into the peritoneal cavity, and because the President's pulse was getting weaker. Moreover, the daylight was rapidly failing. Dr. Roswell Park, who, by virtue of his office, had he been present would have performed the operation, was at Niagara Falls, and although a special train had been sent for him, it was uncertain when he would arrive.

Dr. Mann was selected to do the operation, with Dr. Mynter as his associate, by the common consent of the physicians present and at the request of Mr. Milburn, president of the Pan-American Exposition, who stated that he had been requested by President McKinley to select his medical attendants. Dr. Mann selected Drs. Lee and Parmenter as assistants.

At 5:20 Dr. Mann directed the administration of ether to President McKinley, and requested Dr. Wasdin to administer it. Ether was chosen as being, on the whole, the safer anesthetic. While the anesthetic was being given the surgeons who were to take part in the operation prepared their hands and arms by thoroughly scrubbing with soap and water and immersing them in a solution of bichlorid of mercury.

The operation began at 5:29. Dr. Mann stood upon the right-hand side of the patient, with Dr. Parmenter on his right-hand side. Dr. Mynter stood upon the left-hand side of the patient, and on his right was Dr. Lee. To Drs. Parmenter and Lee were assigned the duties of sponging and the care of the instruments. Dr. P. M. Rixey, U. S. N., President McKinley's family physician, having been detailed by the President to accompany Mrs. McKinley to the Milburn home, did not arrive until 5:30, when he gave very efficient service by guiding the rays of the sun to the seat of the operation by aid of a hand-mirror, and later by arranging an electric light. Dr. Roswell Park arrived just as the operation on the stomach was completed, and gave his aid as consultant. Mr. E. C. Mann had charge of the needles, sutures and ligatures. Mr. Simpson, medical student, was at the instrument tray.

The nurses, under the charge of Miss A. C. Walters, superintendent of the hospital, were Miss M. E. Morris and Miss A. D. Barnes, with hands sterilized; Miss Rose Baron, Miss M. A. Shannon and Miss L. C. Dorchester, assistants, and Miss Katharine Simmons attending the anesthetizer.

Besides those immediately engaged in the operation, there were present Drs. P. W. Van Peyma, Joseph Fowler, D. W. Harrington and Charles G. Stockton, of Buffalo, and Dr. W. D. Storer, of Chicago.

THE OPERATION.

President McKinley took the ether well, and was entirely under its influence in nine minutes after the beginning of the anesthetization. The abdomen was carefully shaved and scrubbed with green soap, and then washed with alcohol and ether and the bichlorid solution.

Inspection showed 2 wounds made by the bullets. The upper one was between the second and third ribs, a little to the right of the sternum. The use of a probe showed that the skin had not been penetrated, but that the bullet had probably struck a button or some object in the clothing which had deflected it. The lower wound made by the other bullet—a 32-caliber—was on a line drawn from the nipple to the umbilicus. It was about half-way between these points, and about 5 cm. to the left of the median line. A probe showed that this wound extended deeply into the abdominal walls, and that the direction was somewhat downward and outward.

An incision was made from the edge of the ribs downward, passing through the bullet wound and nearly parallel with the long axis of the body. A deep layer of fat was opened, and followed by incision of the fascia and muscles to the peritoneum. After cutting through the skin, a piece of cloth, undoubtedly a bit of the President's clothing, was removed from the track of the bullet, a short distance below the skin.

On opening the peritoneum, the finger was introduced and the anterior wall of the stomach palpated. An opening was discovered which would not quite admit the index finger. This opening was located near the greater curvature of the stomach, and about 2 cm. from the attachment of the omentum; its edges were clean-cut and did not appear to be much injured.

The stomach was drawn up into the operation wound, and the perforation very slightly enlarged. The finger was then introduced and the contents of the stomach palpated. This was done to see if the stomach contained food, and also with the hope that possibly the bullet might be in the stomach. The stomach was found to be half-full of liquid food, but no evidence of the ball was discovered. In pulling up the stomach a small amount of liquid contents escaped, together with a good deal of gas. The tissues around the wound were carefully irrigated with hot salt solution and dried with gauze pads. The perforation in the anterior stomach wall was then closed with a double row of silk suture (Czerny-Lembert). The sutures were not interrupted with each stitch, but 4 stitches were introduced before the ends were tied. The loop was then cut off and the suture continued. About 8 stitches were used in each row. The silk used was fine black silk, the needle being a straight, round sewing needle.

In order to examine the posterior wall of the stomach, it was necessary to enlarge the incision, which now reached about 15 cm. in length. The omentum and transverse colon were pulled well out of the abdomen. The omentum was enormously thickened with fat and very rigid. In order to reach the back wall of the stomach, it was necessary to divide about 4 inches of the gastrocolic omentum, the cut ends being tied with strong black silk in 2 masses on each side. In this way the stomach could be drawn up in the operation wound, and the bullet wound in its posterior wall reached. This opening was somewhat larger than that in the anterior wall of the stomach, and had frayed and blood-infiltrated edges. Its exact location was impossible to determine. but it appeared to be near the larger curvature.

This opening was closed in the same way as the anterior wound, but with great difficulty, as the opening was down at the bottom of a deep pocket. A short curved surgical needle was necessary here. Little or no gastric contents appeared around this opening, but after it had been closed the parts were carefully irrigated with hot salt solution.

The operation on the stomach being now finished, Dr. Mann introduced his arm so as to palpate carefully all the deep structures behind the stomach. No trace of the bullet or of the further track of the bullet could be found. As the introduction of the hand in this way seemed to have a bad influence on the President's pulse, prolonged search for further injury done by the bullet or for the bullet itself was desisted from. The folds of the intestine which had been below the stomach were inspected for injury, but none was found. The entire gut was not removed from the abdomen for inspection, as the location of the wound seemed to exclude its injury. To have made a satisfactory search for wounds in the President's back, it would have been necessary to have entirely eviscerated him. As he was already suffering from shock, this was not considered justifiable, and might have caused his death on the operating table.

Before closing the abdominal wound, Dr. Mann asked each of the surgeons present, whether he was entirely satisfied that everything had been done which should be done, and whether he had any further suggestions to make. Each replied that he was satisfied. The question of drainage was also discussed. Dr. Mynter was in favor of a Mikulicz drain being placed down behind the stomach-wall. Dr. Mann, with the concurrence of the other surgeons, decided against this, as being unnecessary.

As the last step in the operation, the tissues around the bullet track in the abdominal wall were trimmed, in order to remove any tissue which might be infected. The abdominal wound was then closed with 7 through-and-through silkworm-gut sutures, drawn only moderately tight, the superior layer of the fascia of the rectus muscle being joined with buried catgut. The edges of the skin were brought together by fine catgut sutures. Where the bullet had entered there was slight gaping of the tissues, but it was not thought advisable to close this tightly, as it might allow of some drainage. The wound was then washed with hydrogen dioxid and covered with aristol powder and dressed with sterilized gauze and cotton, which were held in place with adhesive straps. Over all was put an abdominal bandage.

The President bore the operation very well. The time from the beginning of the administration of the anesthetic until its discontinuance was exactly an hour and 31 minutes; the operation was completed at 6:50 p. m., having lasted from the time of the first incision, an hour and 21 minutes. At the beginning of the operation President McKinley's pulse was 84. At 5:38, 0.002 gm. of strychnin was administered hypodermically. At 5:55 the respiration was 32 and the pulse 84—both good in character. At 6:09 the pulse was 88. At 6:20 it was 102, fair in character; respiration 39. At 6:22, 1.50 gm. of brandy was administered hypodermically. At 6:48 the pulse was 124, the tension good but quick; respiration 36. At 7:01, after the bandage was applied, the pulse was 122 and the respiration 32. At 7:17, 0.004 gm. of morphin was administered hypodermically.

At 7:32 the patient was removed from the hospital in the ambulance. Dr. Rixey asked Drs. Park and Wasdin to go in the ambulance as his duty called him to go at once to inform Mrs. McKinley of her husband's condition and to prepare a room for his reception. Drs. Mann and Mynter, with friends of the President, followed in carriages immediately after. President McKinley had not then recovered from the anesthetic. He bore the journey to Mr. Milburn's house exceedingly well, but it was found necessary to give him a small hypodermic injection of morphin during the transit, as he was becoming very restless. On arrival at the house of Mr. Milburn, 1168 Delaware Avenue, he was removed from the ambulance on the stretcher, and carried to a room in the northwest corner of the house, where a hospital bed had been prepared for him.

REMARKS ON THE OPERATION, BY MATTHEW D. MANN, M.D.

The difficulties of the operation were very great, owing partly to the want of retractors and to the failing light. The setting sun shone directly into the room, but not into the wound. The windows were low and covered with awnings. After Dr. Rixey aided us with a hand mirror, the light was better. Toward the end of the time a movable electric light with reflector was put in use. The greatest difficulty was the great size of President McKinley's abdomen and the amount of fat present. This necessitated working at the bottom of a deep hole, especially when suturing the posterior wall of the stomach.

The operation was rendered possible and greatly facilitated by a good operating table and the other appliances of a hospital, and by the presence of many trained nurses and assistants. Still, the hospital was only equipped for minor emergency work, and had but a moderate supply of instruments. Unfortunately, when called I was not told what I was wanted for, and went to the Exposition grounds entirely unprepared. Dr. Mynter had his large pocket case, the contents of which were of great use.

As has already been noted, further search for the bullet was rendered inadvisable by the President's condition. The autopsy shows that it could not have been found, and that the injuries inflicted by the bullet after it passed through the stomach were of such a nature as to render impossible and unnecessary any further surgical procedure. A bullet after it ceases to move does little harm. We were often asked why, after the operation, we did not use the x-ray to find the bullet. There were several reasons for this. In the first place, there were at no time any signs that the bullet was doing harm. To have used the x-ray simply to have satisfied our curiosity would not have been warrantable, as it would have greatly disturbed and annoyed the patient, and would have subjected him also to a certain risk. Had there been signs of abscess-formation, then the rays could and would have been used.

My reason for not draining was that there was nothing to drain. There had been no bleeding nor oozing; there was nothing to make any discharge or secretion; the parts were presumably free from infection, and were carefully washed with salt solution. As there was no peritonitis and the abdomen was found postmortem to be sterile, we may safely conclude that no drainage could have been provided which would have accomplished anything. My experience teaches me never to drain unless there is a very decided indication for it, as a drain may do harm as well as good.

In conclusion, I wish to thank all the gentlemen who so kindly and skilfully assisted me. They were all surgeons of large experience in abdominal surgery, and their aid and advice were most valuable. Especially I wish to acknowledge my great obligation to my associate, Dr. Mynter. Not only was he an assistant, but he was much more, and helped me greatly by his skill and, as a consultant, with his good judgment and extensive knowledge of abdominal work. Although called first, he waived his claim, and generously placed the case in my hands, willingly assuming his share of the responsibility.

The anesthetic was most carefully administered by Dr. Wasdin, and the knowledge that he had charge of this very important duty relieved me of any anxiety on that score.

In the eventful week that followed the operation, Dr. Park and Dr. McBurney were towers of strength in helping to decide the many difficult questions which came up.

Dr. Rixey was in constant charge of the sick-room, aided later by Dr. Wasdin, who was detailed for this special duty. Both were unremitting in their care, and faithful to the end.

Dr. Stockton helped us in the last 3 days with the highest skill and best judgment.

Never, I am sure, under like circumstances, was there a more harmonious or better-agreed band of consultants. That our best endeavors failed was, I believe, no fault of ours; but it must be an ever-living and keen regret to each of us, that we were not allowed the privilege of saving so noble a man, so attractive a patient, and so useful a life.

THE AFTER-TREATMENT.

When put to bed the President was in fair condition: Pulse, 127; temperature, 100.6 degrees; respiration, 30. The nurses on duty were Miss K. R. Simmons and Miss A. D. Barnes, from the Emergency Hospital. Soon after his arrival, at 8:25, he was given morphin, 0.016 gm., hypodermically. There was slight nausea. The pulse soon improved. During the evening the patient slept at intervals, vomiting occasionally, but rallied satisfactorily. A slight discoloration of the dressings was noted at 10:45. There was occasional and slight pain. Ninety cc. of urine was voided, and an enema of salt solution given and retained.

SECOND DAY, SATURDAY, SEPTEMBER 7.

After midnight the patient slept a good deal; he was free from pain and quite comfortable.

At 6 a. m., the temperature was 102; pulse, 110; respiration, 24.

Gas in large quantities was expelled from the bowels. A saline enema was given as before. Miss Simmons and Miss Barnes were replaced by Miss Maud Mohan and Miss Jane Connolly. Miss E. Hunt, of San Francisco, Cal., Mrs. McKinley's nurse, also rendered assistance, and Miss Grace Mackenzie, of Baltimore, Md., arrived September 9, and was detailed for regular duty. P. A. Eliot, J. Hodgins and Ernest Vollmeyer, of the U. S. A. Hospital Corps, were detailed as orderlies.

During the forenoon, 0.01 gm. of morphin was administered hypodermically.

At 1:15 p. m., a saline enema of 500 cc. was given. As the pulse was rising, 0.06 gm. of fluid extract of digitalis was injected hypodermically.

The President rested quietly until 6:30 p. m., when he complained of intense pain in the pit of the stomach, and was given 0.008 gm. morphin sulphate hypodermically. He was very restless, but after being sponged rested again.

At 6:30 p. m., the pulse was 130; temperature, 102.5; respiration, 29.

During the day the digitalis, morphin and saline enemas were kept up at regular intervals; 4 gm. of somatose were added to the water at 10:30 p. m. At 11:15 p. m. the President passed from the bowels 240 cc. of a greenish colored fluid and some particles of fecal matter.

The total amount of urine for 24 hours was 270 cc.

FIRST URINALYSIS, BY DR. H. G. MATZINGER.

Quantity	30 cc.
Color	dark amber
Reaction	strongly acid
Urea	0.028 gm. per 1 cc. of urine
Albumin	a trace
Phosphates and chlorids	normal
Sugar.	none
Indican	very small amount

Microscopic Examination.—The sediment obtained by centrifuge shows a large amount of large and small epithelial cells with some leucocytes and occasional red cells. There is a comparatively large number of hyaline casts, principally small, with some finely granular ones; also an occasional fibrinous one. The amount of sediment is large for the quantity of urine submitted. There were no crystals in the sediment.

THIRD DAY, SUNDAY, SEPTEMBER 8.

During the early morning the President slept a good deal, but was restless, and at times confused and a little chilly. On the whole, he passed a fairly good night.

He expelled a little gas and brown fluid from the rectum. The digitalis was continued, and at 7:45 a. m., 0.002 gm. of strychnin was given hypodermically. At 8:20 a. m. he was clear and bright, with the pulse strong and of good character.

The wound was dressed at 8:30, and found in a very satisfactory condition. There was no indication of peritonitis. Pulse, 132; temperature, 102.8; respiration, 24.

The dressing on the wound was changed because there was some exudation. The bullet track was syringed out with hydrogen dioxid. There was very little foaming, and there were no signs of pus.

At 10:40 a. m., following an enema of epsom salts, glycerin and water, he had a small stool with gas, and another at noon. He was less restless and slept a good deal.

At noon Dr. Charles McBurney joined the medical staff in consultation, having been summoned by Dr. Rixey.

Bulletin 14, 12 m.—The improvement in the President's condition has continued since the last bulletin. Pulse, 128; temperature, 101°; respiration, 27.

During the day he continued to improve; he slept 4 or 5 hours and his condition was satisfactory.

At 4:45 p. m. he was given a teaspoonful of water by the mouth; also an enema of sweet oil, soap and water. He passed slightly colored fluid with some little fecal matter and mucus. After this he had a small quantity of water by the mouth, and at 6:20 p. m. a nutritive enema of egg, whiskey and water, which was partly retained. Digitalis and strychnin were both given during the evening.

At 9 p. m. the President was resting comfortably. The pulse was 130; temperature, 101.6; respiration, 30.

Four hundred and twenty c.c. of urine were passed during the day.

SECOND URINALYSIS.

Quantity	450 cc.
Color	amber, slightly turbid
Reaction	strongly acid
Specific gravity	1.026
Urea.	0.038 gm. per 1 cc. of urine
Albumin	mere trace
Sugar.	none
Indican	abundant
Sulphates	*increased*
Phosphates	somewhat increased
Chlorids	somewhat increased

Microscopic Examination.—Microscopic examination of sediment obtained by centrifuge shows fewer organic elements. Some large and small epithelial cells and some leucocytes. Casts are not so abundant as yesterday and are *principally* of the small finely granular variety. There is a marked diminution in small renal epithelial cells.

Quite a *quantity of large crystals of uric acid and bacteria* are present.

FOURTH DAY, MONDAY, SEPTEMBER 9.

The bulletins tell the story of the fourth day.

Bulletin 17, 6 a. m.—The President passed a somewhat restless night, sleeping fairly well. General condition unchanged. Pulse, 120; temperature, 101°; respiration, 28.

Bulletin 18, 9:20 a. m.—The President's condition is becoming more and more satisfactory. Untoward incidents are less likely to occur. Pulse, 122; temperature, 100.8°; respiration, 28.

Bulletin 19, 3 p. m.—The President's condition steadily improves and he is comfortable, without pain or unfavorable symptoms. Bowel and kidney functions normally performed. Pulse, 113; temperature, 101°; respiration, 26.

Bulletin 20, 9:30 p. m.—The President's condition continues favorable; Pulse, 112; temperature, 101°; respiration, 27.

Codeia was substituted for morphia, as the pain was less. Digitalis and strychnin were stopped. Nutritive enemas were given at 3:20 a. m., at 4:30 and 10 p. m. Hot water was taken quite freely by the mouth.

Attempts to get a good movement of the bowels were successful at noon, when he had a large, light-brown, partly-formed stool. This followed a small dose of calomel and a high enema of oxgall.

On the whole, the President's condition improved steadily during the day. He slept a good deal and was fairly comfortable. There was no pain on pressure over the abdomen.

THIRD URINALYSIS.

Quantity received	540 cc.
Color	amber, slightly turbid
Specific gravity	1.026
Albumin	a trace
Indican	not so abundant as yesterday
Urea	0.047 gm. per cc. of urine
Chlorids and phosphates	about normal
Sulphates	still somewhat high
Sugar	none

pulled well out of the abdomen. The omentum was enormously thickened with fat and very rigid. In order to reach the back wall of the stomach, it was necessary to divide about 4 inches of the gastrocolic omentum, the cut ends being tied with strong black silk in 2 masses on each side. In this way the stomach could be drawn up in the operation wound, and the bullet wound in its posterior wall reached. This opening was somewhat larger than that in the anterior wall of the stomach, and had frayed and blood-infiltrated edges. Its exact location was impossible to determine. but it appeared to be near the larger curvature.

This opening was closed in the same way as the anterior wound, but with great difficulty, as the opening was down at the bottom of a deep pocket. A short curved surgical needle was necessary here. Little or no gastric contents appeared around this opening, but after it had been closed the parts were carefully irrigated with hot salt solution.

The operation on the stomach being now finished, Dr. Mann introduced his arm so as to palpate carefully all the deep structures behind the stomach. No trace of the bullet or of the further track of the bullet could be found. As the introduction of the hand in this way seemed to have a bad influence on the President's pulse, prolonged search for further injury done by the bullet or for the bullet itself was desisted from. The folds of the intestine which had been below the stomach were inspected for injury, but none was found. The entire gut was not removed from the abdomen for inspection, as the location of the wound seemed to exclude its injury. To have made a satisfactory search for wounds in the President's back, it would have been necessary to have entirely eviscerated him. As he was already suffering from shock, this was not considered justifiable, and might have caused his death on the operating table.

Before closing the abdominal wound, Dr. Mann asked each of the surgeons present, whether he was entirely satisfied that everything had been done which should be done, and whether he had any further suggestions to make. Each replied that he was satisfied. The question of drainage was also discussed. Dr. Mynter was in favor of a Mikulicz drain being placed down behind the stomach-wall. Dr. Mann, with the concurrence of the other surgeons, decided against this, as being unnecessary.

As the last step in the operation, the tissues around the bullet track in the abdominal wall were trimmed, in order to remove any tissue which might be infected. The abdominal wound was then closed with 7 through-and-through silkworm-gut sutures, drawn only moderately tight, the superior layer of the fascia of the rectus muscle being joined with buried catgut. The edges of the skin were brought together by fine catgut sutures. Where the bullet had entered there was slight gaping of the tissues, but it was not thought advisable to close this tightly, as it might allow of some drainage. The wound was then washed with hydrogen dioxid and covered with aristol powder and dressed with sterilized gauze and cotton, which were held in place with adhesive straps. Over all was put an abdominal bandage.

The President bore the operation very well. The time from the beginning of the administration of the anesthetic until its discontinuance was exactly an hour and 31 minutes; the operation was completed at 6:50 p. m., having lasted from the time of the first incision, an hour and 21 minutes. At the beginning of the operation President McKinley's pulse was 84. At 5:38, 0.002 gm. of strychnin was administered hypodermically. At 5:55 the respiration was 32 and the pulse 84—both good in character. At 6:09 the pulse was 88. At 6:20 it was 102, fair in character; respiration 39. At 6:22, 1.50 gm. of brandy was administered hypodermically. At 6:48 the pulse was 124, the tension good but quick; respiration 36. At 7:01, after the bandage was applied, the pulse was 122 and the respiration 32. At 7:17, 0.004 gm. of morphin was administered hypodermically.

At 7:32 the patient was removed from the hospital in the ambulance. Dr. Rixey asked Drs. Park and Wasdin to go in the ambulance as his duty called him to go at once to inform Mrs. McKinley of her husband's condition and to prepare a room for his reception. Drs. Mann and Mynter, with friends of the President, followed in carriages immediately after. President McKinley had not then recovered from the anesthetic. He bore the journey to Mr. Milburn's house exceedingly well, but it was found necessary to give him a small hypodermic injection of morphin during the transit, as he was becoming very restless. On arrival at the house of Mr. Milburn, 1168 Delaware Avenue, he was removed from the ambulance on the stretcher, and carried to a room in the northwest corner of the house, where a hospital bed had been prepared for him.

REMARKS ON THE OPERATION, BY MATTHEW D. MANN, M.D.

The difficulties of the operation were very great, owing partly to the want of retractors and to the failing light. The setting sun shone directly into the room, but not into the wound. The windows were low and covered with awnings. After Dr. Rixey aided us with a hand mirror, the light was better. Toward the end of the time a movable electric light with reflector was put in use. The greatest difficulty was the great size of President McKinley's abdomen and the amount of fat present. This necessitated working at the bottom of a deep hole, especially when suturing the posterior wall of the stomach.

The operation was rendered possible and greatly facilitated by a good operating table and the other appliances of a hospital, and by the presence of many trained nurses and assistants. Still, the hospital was only equipped for minor emergency work, and had but a moderate supply of instruments. Unfortunately, when called I was not told what I was wanted for, and went to the Exposition grounds entirely unprepared. Dr. Mynter had his large pocket case, the contents of which were of great use.

As has already been noted, further search for the bullet was rendered inadvisable by the President's condition. The autopsy shows that it could not have been found, and that the injuries inflicted by the bullet after it passed through the stomach were of such a nature as to render impossible and unnecessary any further surgical procedure. A bullet after it ceases to move does little harm. We were often asked why, after the operation, we did not use the *x*-ray to find the bullet. There were several reasons for this. In the first place, there were at no time any signs that the bullet was doing harm. To have used the *x*-ray simply to have satisfied our curiosity would not have been warrantable, as it would have greatly disturbed and annoyed the patient, and would have subjected him also to a certain risk. Had there been signs of abscess-formation, then the rays could and would have been used.

My reason for not draining was that there was nothing to drain. There had been no bleeding nor oozing; there was nothing to make any discharge or secretion; the parts were presumably free from infection, and were carefully washed with salt solution. As there was no peritonitis and the abdomen was found postmortem to be sterile, we may safely conclude that no drainage could have been provided which would have accomplished anything. My experience teaches me never to drain unless there is a very decided indication for it, as a drain may do harm as well as good.

In conclusion, I wish to thank all the gentlemen who so kindly and skilfully assisted me. They were all surgeons of large experience in abdominal surgery, and their aid and advice were most valuable. Especially I wish to acknowledge my great obligation to my associate, Dr. Mynter. Not only was he an assistant, but he was much more, and helped me greatly by his skill and, as a consultant, with his good judgment and extensive knowledge of abdominal work. Although called first, he waived his claim, and generously placed the case in my hands, willingly assuming his share of the responsibility.

The anesthetic was most carefully administered by Dr. Wasdin, and the knowledge that he had charge of this very important duty relieved me of any anxiety on that score.

In the eventful week that followed the operation, Dr. Park and Dr. McBurney were towers of strength in helping to decide the many difficult questions which came up.

Dr. Rixey was in constant charge of the sick-room, aided later by Dr. Wasdin, who was detailed for this special duty. Both were unremitting in their care, and faithful to the end. Dr. Stockton helped us in the last 3 days with the highest skill and best judgment.

Never, I am sure, under like circumstances, was there a more harmonious or better-agreed band of consultants. That our best endeavors failed was, I believe, no fault of ours; but it must be an ever-living and keen regret to each of us, that we were not allowed the privilege of saving so noble a man, so attractive a patient, and so useful a life.

THE AFTER-TREATMENT.

When put to bed the President was in fair condition: Pulse, 127; temperature, 100.6 degrees; respiration, 30. The nurses on duty were Miss K. R. Simmons and Miss A. D. Barnes, from the Emergency Hospital. Soon after his arrival, at 8:25, he was given morphin, 0.016 gm., hypodermically. There was slight nausea. The pulse soon improved. During the evening the patient slept at intervals, vomiting occasionally, but rallied satisfactorily. A slight discoloration of the dressings was noted at 10:45. There was occasional and slight pain. Ninety cc. of urine was voided, and an enema of salt solution given and retained.

SECOND DAY, SATURDAY, SEPTEMBER 7.

After midnight the patient slept a good deal; he was free from pain and quite comfortable.

At 6 a. m., the temperature was 102; pulse, 110; respiration, 24.

Gas in large quantities was expelled from the bowels. A saline enema was given as before. Miss Simmons and Miss Barnes were replaced by Miss Maud Mohan and Miss Jane Connolly. Miss E. Hunt, of San Francisco, Cal., Mrs. McKinley's nurse, also rendered assistance, and Miss Grace Mackenzie, of Baltimore, Md., arrived September 9, and was detailed for regular duty. P. A. Eliot, J. Hodgins and Ernest Vollmeyer, of the U. S. A. Hospital Corps, were detailed as orderlies.

During the forenoon, 0.01 gm. of morphin was administered hypodermically.

At 1:15 p. m., a saline enema of 500 cc. was given. As the pulse was rising, 0.06 gm. of fluid extract of digitalis was injected hypodermically.

The President rested quietly until 6:30 p. m., when he complained of intense pain in the pit of the stomach, and was given 0.008 gm. morphin sulphate hypodermically. He was very restless, but after being sponged rested again.

At 6:30 p. m., the pulse was 130; temperature, 102.5; respiration, 29.

During the day the digitalis, morphin and saline enemas were kept up at regular intervals; 4 gm. of somatose were added to the water at 10:30 p. m. At 11:15 p. m. the President passed from the bowels 240 cc. of a greenish colored fluid and some particles of fecal matter.

The total amount of urine for 24 hours was 270 cc.

FIRST URINALYSIS, BY DR. H. G. MATZINGER.

Quantity	30 cc.
Color	dark amber
Reaction	strongly acid
Urea	0.028 gm. per 1 cc. of urine
Albumin	a trace
Phosphates and chlorids	normal
Sugar.	none
Indican	very small amount

Microscopic Examination.—The sediment obtained by centrifuge shows a large amount of large and small epithelial cells with some leucocytes and occasional red cells. There is a comparatively large number of hyaline casts, principally small, with some finely granular ones; also an occasional fibrinous one. The amount of sediment is large for the quantity of urine submitted. There were no crystals in the sediment.

THIRD DAY, SUNDAY, SEPTEMBER 8.

During the early morning the President slept a good deal, but was restless, and at times confused and a little chilly. On the whole, he passed a fairly good night.

He expelled a little gas and brown fluid from the rectum. The digitalis was continued, and at 7:45 a. m., 0.002 gm. of strychnin was given hypodermically. At 8:20 a. m. he was clear and bright, with the pulse strong and of good character.

The wound was dressed at 8:30, and found in a very satisfactory condition. There was no indication of peritonitis. Pulse, 132; temperature, 102.8; respiration, 24.

The dressing on the wound was changed because there was some exudation. The bullet track was syringed out with hydrogen dioxid. There was very little foaming, and there were no signs of pus.

At 10:40 a. m., following an enema of epsom salts, glycerin and water, he had a small stool with gas, and another at noon. He was less restless and slept a good deal.

At noon Dr. Charles McBurney joined the medical staff in consultation, having been summoned by Dr. Rixey.

Bulletin 14, 12 m.—The improvement in the President's condition has continued since the last bulletin. Pulse, 128; temperature, 101°; respiration, 27.

During the day he continued to improve; he slept 4 or 5 hours and his condition was satisfactory.

At 4:45 p. m. he was given a teaspoonful of water by the mouth; also an enema of sweet oil, soap and water. He passed slightly colored fluid with some little fecal matter and mucus. After this he had a small quantity of water by the mouth, and at 6:20 p. m. a nutritive enema of egg, whiskey and water, which was partly retained. Digitalis and strychnin were both given during the evening.

At 9 p. m. the President was resting comfortably. The pulse was 130; temperature, 101.6; respiration, 30.

Four hundred and twenty c.c. of urine were passed during the day.

SECOND URINALYSIS.

Quantity	450 cc.
Color	amber, slightly turbid
Reaction	strongly acid
Specific gravity	1.026
Urea.	0.038 gm. per 1 cc. of urine
Albumin	mere trace
Sugar.	none
Indican	abundant
Sulphates	increased
Phosphates	somewhat increased
Chlorids	somewhat increased

Microscopic Examination.—Microscopic examination of sediment obtained by centrifuge shows fewer organic elements. Some large and small epithelial cells and some leucocytes. Casts are not so abundant as yesterday and are *principally* of the small finely granular variety. There is a marked diminution in small renal epithelial cells.

Quite a quantity of large crystals of uric acid and bacteria are present.

FOURTH DAY, MONDAY, SEPTEMBER 9.

The bulletins tell the story of the fourth day.

Bulletin 17, 6 a. m.—The President passed a somewhat restless night, sleeping fairly well. General condition unchanged. Pulse, 120; temperature, 101°; respiration, 28.

Bulletin 18, 9:20 a. m.—The President's condition is becoming more and more satisfactory. Untoward incidents are less likely to occur. Pulse, 122; temperature, 100.8°; respiration, 28.

Bulletin 19, 3 p. m.—The President's condition steadily improves and he is comfortable, without pain or unfavorable symptoms. Bowel and kidney functions normally performed. Pulse, 113; temperature, 101°; respiration, 26.

Bulletin 20, 9:30 p. m.—The President's condition continues favorable; Pulse, 112; temperature, 101°; respiration, 27.

Codeia was substituted for morphia, as the pain was less. Digitalis and strychnin were stopped. Nutritive enemas were given at 3:20 a. m., at 4:30 and 10 p. m. Hot water was taken quite freely by the mouth.

Attempts to get a good movement of the bowels were successful at noon, when he had a large, light-brown, partly-formed stool. This followed a small dose of calomel and a high enema of oxgall.

On the whole, the President's condition improved steadily during the day. He slept a good deal and was fairly comfortable. There was no pain on pressure over the abdomen.

THIRD URINALYSIS.

Quantity received	540 cc.
Color	amber, slightly turbid
Specific gravity	1.026
Albumin	a trace
Indican	not so abundant as yesterday
Urea	0.047 gm. per cc. of urine
Chlorids and phosphates	about normal
Sulphates	still somewhat high
Sugar	none

Microscopic Examination.—Microscopic examination of sediment obtained by centrifuge shows a decrease in the amount of organic elements and an increase of amorphous urates, but fewer crystals of uric acid. Casts are fewer and only the small granular and large hyaline varieties. The proportion of casts is greater. There are very few epithelial cells, mostly of renal type. A large number of cylindroids are found.

FIFTH DAY, TUESDAY, SEPTEMBER 10.

Soon after midnight the President had a high enema of soap and water, which was expelled, together with some fecal matter. He took hot water frequently, and slept a good deal.

Bulletin 21, 5:20 a. m.—The President has passed the most comfortable night since the attempt on his life. Pulse, 118; temperature, 100.4°; respiration, 28.

On awaking he felt very comfortable, and his mind was clear and cheerful. The nutritive enemas were kept up, and water given by the mouth. Had 2 small stools during the day. The only medicine given was one hypodermic of codeia phosphate, 0.015 gm.

In the evening the dressings were examined, and as there was considerable staining from the discharge, it was thought best to remove four stitches and separate the edges of the wound. A little slough was observed near the bullet track, covering a space nearly an inch wide, the thickness of the flaps. The separation seemed to extend down to the muscle. The surfaces, except those mentioned, looked healthy, but not granulating. It was supposed that the infection of the wound occurred either from the bullet or from the piece of clothing carried into the wound at the time of the shooting. The parts were thoroughly washed with hydrogen dioxid and packed lightly with gauze, and held together with adhesive straps.

SIXTH DAY, WEDNESDAY, SEPTEMBER 11.

Bulletin 26, 9 a. m.—The President rested comfortably during the night. Decided benefit has followed the dressing of the wound made last night. His stomach tolerates the beef juice well, and it is taken with great satisfaction. His condition this morning is excellent. Pulse, 116; temperature, 100.2°.

Bulletin 27, 3:30 p. m.—The President continues to gain, and the wound is becoming more healthy. The nourishment taken into the stomach is being gradually increased. Pulse, 120; temperature, 100.2°.

Bulletin 28, 10 p. m.—The President's condition continues favorable. Blood count corroborates clinical evidence of the absence of any blood poisoning. He is able to take more nourishment and relish it. Pulse, 120; temperature, 100.4°.

The blood count made by Dr. Wasdin in the evening was as follows:

Leucocytes	6,752
Red cells	3,920,000

A little after midnight, Wednesday morning, the patient was given 4 cc. of beef juice, the first food taken by the stomach. It seemed to be very acceptable. Nutritive enema was given at 2 a. m.; later there was a yellow stool.

From 4 to 8 c.c. of beef juice were given every 1 to 2 hours during the day. The rectum was becoming irritable, and did not retain the nutritive enemas well.

At 10 a. m. the remaining stitches were removed, the wound separated and dressed. It seemed to be doing well. Most of the sloughing tissue had separated.

The patient slept much during the day, and expressed himself as feeling very comfortable. The only medicine administered was 1 hypodermic of strychnin.

In the evening he was changed to a fresh bed. Nutritive enemas were continued.

Urine was passed much more freely—750 cc. in 24 hours.

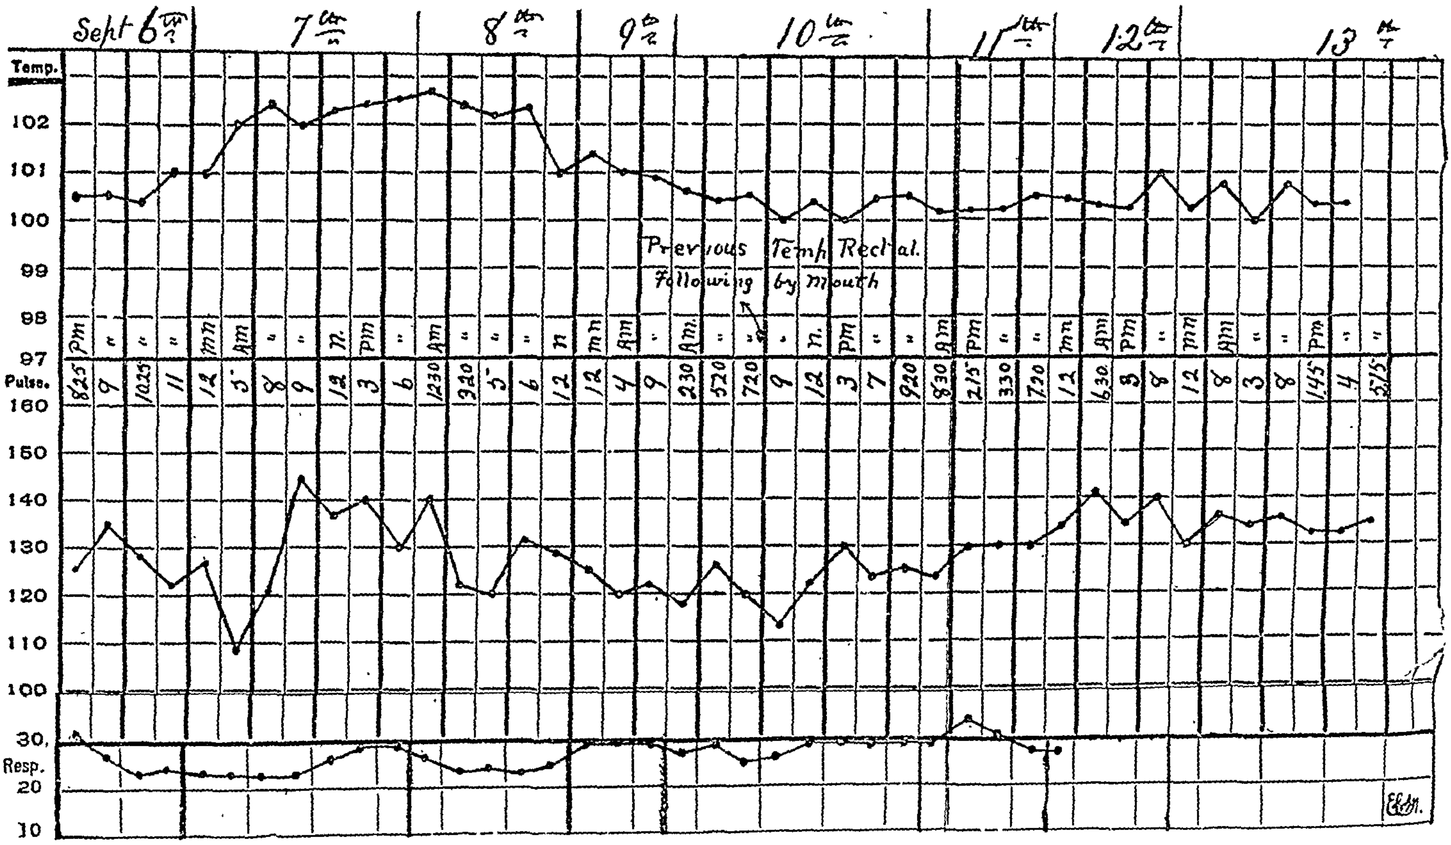

CHART OF PULSE, TEMPERATURE AND RESPIRATIONS. CASE OF PRESIDENT M'KINLEY.

FOURTH URINALYSIS.

Quantity	82 cc.
Color	amber, clear
Specific gravity	1.027
Reaction	strongly acid
Albumin	a trace
Indican	abundant
Urea	0.04 gm. per 1 cc. of urine
E. phosphates and chlorids	normal
Sulphates	still a little high

Microscopic Examination.—Microscopic examination of sediment obtained by centrifuge shows a marked diminution in amount of organic elements, but a great increase in uric acid crystals.

There are very few epithelial cells—mostly of renal type.

There are fewer casts—small and large hyaline—some finely granular.

Cylindroids are more abundant.

SEVENTH DAY, THURSDAY, SEPTEMBER 12.

The President slept a good deal during the night and awoke in the morning feeling better. The beef juice was continued and increased, and a little chicken broth added to the dietary. He also had a little whiskey and water.

At 8:30 a. m. he had chicken broth, a very small piece of toast and a small cup of coffee. He did not care for the toast, and ate scarcely any of it.

The wound was dressed and washed with a weak solution of iodin and then with hydrogen dioxid. He was given 30 cc. of castor oil at 9:20 a. m.

The President now seemed at his best and his condition to warrant the favorable prognosis given out. The time for peritonitis and sepsis had passed. The bowels had moved and gas passed freely, showing that there was no obstruction. The tongue was clear, and the appetite increasing; and he seemed to be able to digest food. There was no pain nor tenderness in the abdomen, and he was able to turn easily and to sleep on his side. The urine was steadily increasing. His spirits were good and his mind clear, while his pulse, though frequent, was strong and of good quality, and the temperature low.

The analysis of the urine gave no uneasiness, as the amount of urea was fair; there was no albumin worth considering, and the casts were rapidly diminishing. There were no more of them than are found in a large percentage of cases following a long operation under ether. The excess of indican was taken to mean merely some intestinal indigestion, and to be of no serious import. The only symptom to cause any uneasiness was the frequency of the pulse. Still, anxiety on this score was relieved by knowing that the President had naturally a rapid pulse, and that it was easily excited. The open wound was not considered important. It looked healthy, and, although it would take a long time to heal, in itself it was evidently causing no harm, nor was it likely to.

Dr. McBurney left Buffalo for his home in the morning, having arranged to return at once if his presence was desired.

Toward noon it was noticed that the character of the pulse was not quite so good. Infusion of digitalis, 8 cc., was ordered, *and strychnin, 0.002 gm.*

It was thought probable that there was some intestinal toxemia, as there had been no free movement from the bowel since food had been begun, the oil having failed to act. Gradually the pulse went to 130, and grew weaker.

Dr. Charles G. Stockton was added to the medical staff in consultation. At 7 p. m. the President was given 0.20 gm. of calomel.

Bulletin 32, 8:30 p. m.—The President's condition this evening is not quite so good. His food has not agreed with him, and has been stopped. Excretion has not yet been properly established. The kidneys are acting well. His pulse is not satisfactory, but has improved in the last two hours. The wound is doing well. He is resting quietly. Temperature, 100.2°; *pulse, 128.*

At *9:30* p. m. a second dose of 30 cc. of castor oil was given, followed by a high enema of oxgall. This resulted in a large, *dark* semifluid stool, which seemed to exhaust him somewhat. Stimulants were given freely. No more beef juice or food was given. The pulse grew rapidly worse, but *at midnight* there seemed some improvement, as bulletin 33 shows. At 11 p. m. *420* cc. of normal salt solution were given subcutaneously.

Bulletin 33, 12 m.—All unfavorable symptoms in the President's condition have improved since the last bulletin. Pulse, 120; temperature, 100.2°.

FIFTH URINALYSIS.

Quantity	132 cc.
Color	light amber, very turbid
Specific gravity	1.025
Reaction	acid
Albumin	mere trace, if any
Indican	less
Urea	0.044 gm. per 1 cc. of urine
Sulphates	about normal
E. phosphates	*much increased*
Chlorids	normal

Microscopic Examination.—Microscopic examination of sediment *obtained* by centrifuge shows fewer organic elements than the last examination. There is less uric acid and a large amount of amorphous phosphates. Renal casts, about as in the last *examination*, with very few cylindroids.

EIGHTH DAY, FRIDAY, SEPTEMBER 13.

At midnight the pulse was fairly good, 132. *Strychnin and* whiskey were given at intervals, and hypodermics of camphorated oil.

Bulletin 34, 2:50 a. m.—The President's condition is very serious, and gives rise to the gravest apprehension. His bowels have moved well, but his heart does not respond properly to stimulation. He is conscious. The skin is warm, and the pulse *small, regular, easily compressible,* 126; respiration, 30; temperature, 100°.

The wound had been dressed regularly in the manner described 3 times a day. At 9 a. m. the dressing was changed, and a mixture of balsam of Peru and glycerin put in on gauze after the douching.

Stimulants were *continued* as before, but more freely. Coffee, 45 cc., and clam broth, 60 cc., were given; also liquid *peptonoids.*

At 8:30, 1.50 gm. of adrenalin were given hypodermically, and repeated at 9:40.

At 10 a. m., *nearly 2 pints of normal salt solution* were given under the skin, and a pint containing adrenalin at 6 p. m. Nitroglycerin and camphor were also injected at various times, together with brandy and strychnin.

Stimulants as detailed above were used freely all day.

Three-thirty p. m.:Pulse growing weaker.

Five p. m.: Oxygen given and continued for some hours.

Six-thirty p. m.: Last bulletin, No. 39:

Bulletin 39, 6:30 p. m.—The President's physicians report that his condition is most serious in spite of vigorous stimulation. The depression continues and is profound. Unless it can be relieved, the end is only a question of time.

At 6:35 p. m., and again at 7:40, morphin was given hypodermically, as he was very restless and seemed to be suffering.

Nine p. m.: Heart sounds very feeble.

The President continued to sink, becoming weaker and weaker.

At 10 p. m. the oxygen was discontinued. The heart sounds were very feeble and consciousness lost.

The President died at 2:15 *a. m., September 14.*

Drs. E. J. Janeway and W. W. Johnston, *who at the request* of Dr. Rixey had been summoned in *consultation, arrived too* late, but were present at the autopsy. Dr. McBurney also returned on Friday afternoon.

SIXTH URINALYSIS.

Color	amber, turbid, with phosphates
Quantity	252 cc.
Reaction	acid
Specific gravity	1.023
Albumin	mere trace, if any
Urea	0.047 gm. per 1 cc. urine
Indican	a trace
E. phosphates	increased
Chlorids	normal
Sulphates	a little high

Microscopic Examination.—Microscopic examination of sediment *obtained by* centrifuge, before and after clearing, shows no change from yesterday's sample. Casts, hyaline and granular, both large and small, comparatively few. Cylindroids, a few. Crystals, large amount *of uric acid,* some sodium urate, and in the untreated specimen a large amount *of amorphous* deposit, *principally of phosphates.* There are a few epithelial cells, small, granular. Occasional red cells and leucocytes.

REPORT ON THE AUTOPSY.[1]

BY

HARVEY B. GAYLORD, M.D.

Pathologist to the New York State Pathological Laboratory.

Ordinary signs of death: ecchymosis in dependent portions of the body. Rigor mortis well marked. Upon the surface of the chest, to the right of the midsternal line, *a spot 1 cm. in diameter,* dark-red in color, with a *slight crust formation covering it, 5.5 cm.* from the suprasternal notch; from the *right nipple, 10 cm.; from* the line of the right nipple, *8.25 cm.* Surrounding this spot, at which point there is an evident *dissolution of the continuity* of the skin, is a discolored *area of oval shape* extending upward and to the right. In its greatest length it is 11 cm.; and in its *greatest width, 6 cm.* It extends upward in the direction of the *right shoulder. The skin* within this area is discolored, greenish-yellow and mottled.

The surface of the abdomen is covered *with a surgical dressing,* which extends down to the umbilicus and upward to just below *the nipples. The* innermost layer of cotton is *covered or stained* with *balsam of* Peru and blood. On removing this dressing, a wound, parallel to, and somewhat to the left of, *the median line,* is exposed, inserted in which are two layers of gauze, likewise impregnated with *balsam of* Peru. The wound is 14.5 cm. in length, and is open down to the abdominal muscles. The layer of abdominal fat is 3.75 cm. in thickness. The *appearance of the fat is good,* a bright yellow in color. No evidence of necrosis or sloughing. In the left margin of the surgical wound, lying 1 cm. *to the right of a line* drawn from the umbilicus to the left nipple, *15.5 cm.* from the nipple and 16.5 cm. from the umbilicus is a partly healed indentation of the skin, and an excavation of the fat immediately beneath it (this is the site of the entry of the bullet), extending down to the peritoneal surface. On making the median incision, starting from the suprasternal notch and extending to a point just below the symphysis, the subcutaneous fat is exposed, which is of bright yellow color and normal appearance except in an area which corresponds superficially to the area of discoloration described as surrounding the wound upon the chest wall. This area marks the site of a hemorrhage into the subcutaneous fat. The remainder of the subcutaneous fat is firm, and measures 4.75 cm. in thickness on the abdominal wall. On opening the sheath of the right rectus muscle, it is seen to be of dark-red color. (Culture taken from ecchymotic tissue under the upper bullet hole and from between the folds of the small intestine. Three tubes from each locality on agar and gelatin.)

---

[1] The autopsy was performed by Drs. Gaylord and Matzinger.

On opening the abdominal cavity, the parietal surface of the peritoneum is exposed, and is found to be covered with a slight amount of bloody fluid; is perfectly smooth and not injected. The great omentum extends downward to a point midway between the umbilicus and the symphysis. It is thick, firm; its inferior border is discolored by coming in contact with the intestines. Below the umbilicus a few folds of intestines are exposed. These are likewise covered with discolored blood, after the removal of which the peritoneal surface is found to be shiny. On the inner aspect of the abdominal wound the omentum is found to be slightly adherent to the parietal peritoneum, and can be readily separated with the hand from the edge of the wound. At this point the omentum is somewhat injected. This adhesion to the omentum is found to extend entirely around the abdominal wound. The parietal peritoneum immediately adjacent to the inner aspect of the abdominal wound is ecchymotic.

On removing the subcutaneous fat and muscles from the thoracic wall, the point which marks the dissolution of continuity of the skin upon the surface, is found to lie directly over the margin of the sternum and to the right side between the second and third ribs. There is no evidence of ecchymosis or injury to the tissues or muscles beneath the subcutaneous fat. On making an incision through the subcutaneous fat, directly through the wound upon the chest, a small cavity is exposed about the size of a pea just beneath the skin which is filled with fluid blood. The subcutaneous tissue underlying the area of discoloration on the surface of the chest wall shows hemorrhagic infiltration.

On removing the sternum, the lungs are exposed, and do not extend far forward. A large amount of pericardial fat is exposed. Pleural surface on both sides is smooth. There are no adhesions on either side within the pleural cavities. The diaphragm on the right side extends upward to a point opposite the third rib in the mammary line. No perceptible amount of fluid in either pleural cavity. On opening the pericardial cavity, the surface of the pericardium is found to be smooth and pale. The pericardium contains approximately 6 cc. of straw-colored, slightly turbid fluid. (Some taken for examination.)

On exposing the heart, it is found covered with a well-developed panniculus. The heart measures, from the base to the apex, on the superficial aspect, 10.5 cm. The right ventricle is apparently empty. The heart feels soft and flaccid. On opening the left ventricle, a small amount of dark-red blood is found. The muscle of the left ventricular wall is 1.5 cm. in thickness; dark reddish-brown in color; presents a shiny surface. The average thickness of the pericardial fat is 3.5 mm. (Cultures made from the auricle.) The left auricle contains but a small amount of dark currant-colored blood. The mitral valve admits 3 fingers. The right ventricle, when incised in the anterior line, is found to be extremely soft: the muscular structure is 2 mm. in thickness. The panniculus measures 7 mm. The muscle is dark red in color; very shiny, and the pericardial fat invades the muscular wall at many points.

On opening the right auricle it is found to be filled and distended by a large currant-colored clot, which extends into the vessels. The tricuspid orifice admits readily three fingers. The coronary arteries are patulous and soft; no evidence of thickening.

Lungs are gray color, and contain a moderate amount of coal-dust pigment. Slight amount of frothy fluid escapes from the bronchi; but the pulmonary tissue is crepitant and free from exudate.

On unfolding the folds of intestine, there is no evidence of adhesion until a point just beneath the mesocolon is reached, when, on removing a fold of small intestine, a few spoonfuls of greenish-gray thick fluid flows into the peritoneal cavity.

On the anterior gastric wall is an area to which a fold of the gastrocolic omentum is lightly adherent. On breaking the adhesion there is found a wound about midway between the gastric orifices, 3.5 cm. in length, parallel with the greater curvature of the stomach, 1.5 cm. from the line of omental attachment. This wound is held intact by silk sutures. There is no evidence of adhesion at any other point on the anterior wall. The gastric wall surrounding the wound just mentioned for a distance of 2 cm. to 3 cm. is discolored, dark greenish-gray in appearance, and easily torn. On exposing the posterior wall of the stomach from above, along its greater curvature, the omentum is found to be slightly adherent, a line of silk ligatures along the greater curvature of the stomach marking the site where the omentum had been removed. On throwing the omentum downward, the posterior gastric wall is exposed. On the posterior wall, a distance of 2 cm. from the line of omental attachment, is a wound approximately 2 cm. long, held intact by silk sutures. The gastric wall surrounding this wound is discolored. On the surface of the mesocolon, which is posterior to the gastric wall at this point, is a corresponding area of discoloration, the portion coming directly in contact with the wound in the gastric wall being of dull gray color. The remainder of the surface of the posterior wall of the stomach is smooth and shiny. Beyond the surgical wound in the posterior wall of the stomach is found an opening in the retroperitoneal fat, large enough to admit 2 fingers. This opening communicates with a track which extends downward and backward as far as the finger can reach. The tissues surrounding this track are necrotic. On removing the descending portion of the colon, a large irregular cavity is exposed, the walls of which are covered with gray, slimy material, and in which are found fragments of necrotic tissue. Just at the superior margin of the kidney is located a definite opening which forms the bottom of the track traced from the stomach. On stripping the left kidney from its capsule, it is found that the superior portion of the capsule is continuous with the cavity. The weight of the left kidney is 141.82 grams. The kidney is readily stripped from its capsule: is dark red; the stellate veins are prominent, and along its greater curvature are numerous dark red depressions. On the superior aspect of the kidney is a protrusion of the cortex, dark red in color, and in this protrusion is a laceration 2 cm. long, extending across the superior border, approximately at right angles to the periphery of the kidney and from before backward. On incising the kidney, the cortex and medulla are not easily distinguishable from one another; both are of rose-red color, the cortex measuring approximately 6 mm. in thickness. The vessels in the pyramids of Ferrein are very prominent. Beneath the protruding portion of the surface, the cortex is dark red in color. This discoloration extends downward in pyramidal form into the medulla. The laceration of the surface marks the apex of the protrusion of the kidney substance. Between the spleen and the superior aspect of the kidney is a necrotic tract which extends down and backward, and ends in a blind pocket. The tract which included the superior aspect of the kidney can be traced into the perinephritic fat to a point just above the surface of the muscles of the back.

The necrotic cavity which connects the wound on the posterior wall of the stomach and the opening adjacent to the kidney capsule is walled off by the mesocolon, and is found to involve an area of the pancreas, approximately 45 mm. in diameter and extending about half through the organ. This organ at its center forms part of the necrotic cavity. Through its body are found numerous minute hemorrhages and areas of gray softening, the size of a pea or smaller. These are less frequent in the head portion of the pancreas.

A careful examination of the track leading down toward the dorsal muscles fails to reveal the presence of any foreign body. After passing into the fat, the direct character of the track ceases; and its direction can be traced no further. The adjoining fat and the muscles of the back were carefully palpated and incised, without disclosing a wound or the presence of a foreign body. The diaphragm was carefully dissected away, and the posterior portion of the thoracic wall likewise carefully examined. All fat and organs which were removed, including the intestine, were likewise examined and palpated, without result.

The great amount of fat in the abdominal cavity and surrounding the kidney rendered the search extremely difficult.

The right kidney is imbedded in a dense mass of fat; capsule strips freely; it weighs 141.75 grams; measures 11.5 cm.; substance is soft; cortex is 6 mm. in thickness; rose-red in color: cut surface slightly dulled. There are a few depressions of the surface, and the stellate veins are prominent.

The liver is dark-red in color; the gall-bladder distended. The organ was not removed.

The autopsy continued for a longer period than was anticipated by those who had charge of the President's body, and we were requested to desist seeking for the bullet and terminate the autopsy. As we were satisfied that nothing could be gained by locating the bullet, which had apparently set up no reaction, search for it was discontinued.

Anatomic Diagnosis.—Gunshot wound of both walls of the stomach and the superior aspect of the left kidney; extensive necrosis of the substance of the pancreas; necrosis of the gastric wall in the neighborhood of both wounds; fatty degeneration, infiltration and brown atrophy of the heart muscle; slight cloudy swelling of the epithelium of the kidneys.

A matter of no inconsiderable embarrassment to us arose in the objection to our removing sufficient portions of the tissues for examination. We were able to secure only 2 small fragments of the stomach wall; tissue from around the wound upon the chest wall; a portion of fat from the wall of the necrotic cavity: a small piece of each kidney, that of the left kidney including the portion involved by the original wound; and pieces of heart-muscle from the right and left ventricles. The microscopic examination of these tissues follows:

The piece of retroperitoneal fat, where it forms part of the necrotic cavity, is seen on section to be covered with a thick gray deposit, which has an average thickness of from 4 mm. to 6 mm. Beneath this, and separating it from the fat, is a well-defined area of hemorrhage from 1 mm. to 2 mm. in thickness. The appearance of this piece of tissue is characteristic of the fat tissue surrounding the entire cavity. A section made perpendicular to the surface and stained with hematoxylin-eosin, shows the following characteristics: Under low power there is no evidence of round-celled infiltration between the fat cells, or of fat necroses. The surface of the tissue which, in the microscopic specimen was covered by a layer of grayish material, proves, under low power to consist of a partly organized fibrinous deposit. At the base of this deposit is evidence of an extensive hemorrhage, marked by deposits of pigment. The surface of the membrane is of rough and irregular appearance, and contains a large number of round cells with deeply stained nuclei. Under high power the organization of the membrane may be traced from the base toward the surface. The portion immediately adjacent to the fat tissue consists of a network of fibrin enclosing large numbers of partly preserved red blood corpuscles. In many areas the red blood corpuscles are broken down and extensive deposits of pigment are found. Extending into the fibrin structure of the membrane are numerous typical fibroblasts and round cells. In some regions pigment is evidently deposited in the bodies of large branching and spindle cells. Here and there, included in the membrane, are the remains of fat cells, and toward the surface of the membrane a large number of round cells scattered through the interstices of the membrane. There are but few polymorphonuclear leucocytes. Here and there in the membrane are fragments of isolated fibrous connective tissue with irregular contours and an appearance suggesting that they are fragments of tissue which have been displaced by violence and included in the fibrin deposit. The fibrin in the superficial layers of the membrane is formed in hyaline clumps. The organization along the base of the deposit is comparatively uniform.

Sections stained with methylene blue, carbol-thionin and Gram's method were carefully examined for the presence of bacteria, with negative results. Even upon the surface of the membrane there are no evidences of bacteria.

The section of the left kidney including the triangular area of hemorrhage described in the macroscopic specimen, reveals the following appearances. (Section hardened in formalin, stained with hematoxylin-eosin.) Examined macroscopically, section represents a portion of a kidney cortex made perpendicular to the surface of the cortex, and including an area of hemorrhage into the substance of the cortex 1 cm. in length measured from the capsular surface downward, and presenting a width of from 5 mm. to 6 mm. The capsular surface has apparently been torn.

Under low power the margins of the preparation are found to consist of well-preserved kidney structure. There is a slight amount of thickening of the interstitial tissue, and occasional groups of tubules are affected by beginning cloudy swelling. The glomeruli are large and present a perfectly normal appearance. As we approach toward the center of the preparation, occasional glomeruli are met with in which the capillary loops are engorged and the adjacent tubules contain red blood-corpuscles. A short distance further, the kidney structure becomes entirely necrotic. Here and there the remains of tubules may be made out, and these are infiltrated with cells. The necrotic area presents a rough, net-like structure. As we approach toward the surface of the kidney, we find that the necrosis becomes more marked. There is the merest suggestion of kidney structure, its place being taken by disintegrated red blood-cells and leucocytes, embedded in a well-defined fibrinous network. There is great distortion of the kidney structure about the periphery of the necrotic area. In this region a considerable amount of pigment is also found in the necrotic tissues.

Under high power, the characteristics of the necrotic tissues may be better observed. The kidney structure is broken up and torn into irregular fragments, infiltrated by red blood corpuscles and leucocytes. In the portion of the necrotic mass beneath the capsule, the kidney structure is practically obliterated and is replaced by a network of fibrin, which includes large numbers of red blood-cells and leucocytes. Scattered through the entire necrotic area are frequent deposits of pigment. In the deeper portions of the necrotic area, the margins of the fibrin deposit are invaded by fibroblasts from the connective tissue structure of the kidney. The organization in these areas is, however, slight.

Sections stained with methylene-blue and Gram's method and carefully examined under oil immersion, fail to reveal the presence of any organisms. In preparations stained with methylene blue, the deposits of pigment may be readily observed. Section of the same tissue hardened in Hermann's solution and examined for fat, shows the presence of numerous fat droplets within the epithelium of the tubules which are adjacent to the area of necrosis. In the portions of the preparation more widely distant from the area of necrosis, no fat is present.

Section of the right kidney hardened in formalin and stained with hematoxylin-eosin, reveals the presence of areas in which slight parenchymatous degeneration of the epithelium in the uriniferous tubules may be noted. These areas are not extensive, and are confined to single groups of tubules. The interstitial connective tissue of the organ seems to be slightly increased in amount, but there is no well-defined round-celled infiltration. An occasional hyaline glomerulus is to be met with in these cases surrounded by increased connective tissue. The epithelium of the kidney tubules, aside from those in which the parenchymatous degeneration is present, is well preserved. The nuclei are well stained; protoplasm, finely granular.

A fragment of the stomach wall taken from the immediate neighborhood of the anterior wound is in a condition of complete necrosis. The nuclei of the cells are scarcely demonstrable. The epithelial surface is recognized with difficulty. At its base are apparently a few round cells. Examination of the blood-vessels reveals nothing characteristic. There is apparently no evidence of thrombosis. A section made through the gastric wall at some distance from the wound, reveals the well-preserved muscular structure of the gastric wall, which presents no characteristic alterations. Superficial portions of the epithelium have apparently been affected by postmortem digestion. However, in one portion of the preparation, the epithelium is intact, and shows distinct evidence of marked round-celled infiltration between the glandular structures. The blood vessels contained blood-corpuscles with the usual number of leucocytes.

The fragments of heart-muscle which were removed from the right and left ventricular walls, were examined in the fresh state, and exhibited a well-defined fatty degeneration of the muscle fibers, and in the case of the right ventricular wall, an extensive infiltration between the muscle fibers, of fat, was apparent. Sections from these fragments of muscle hardened in Hermann's solution, are taken for examination. A fragment of muscle from the right ventricular wall was removed at a point where the fat penetrated deeply into the muscular structure, the ventricular wall at this point showing an average thickness of 2.5 mm. Under low power, the muscle fibers are separated into bundles by masses and rows of deeply stained fat cells. The muscle fibers are seen to contain groups of dark brown granules lying in the long axes of the cells. Under high power, these are resolved into extensive groups of dark brown pigment arranged around the nuclei. The muscle fibers are slender, the cross and longitudinal striation is well-defined. Examined near the margin of the preparation, where the osmic-acid fixation has been successful, all of the muscle fibers are found to contain minute black spherical bodies, extending diffusely through all the muscle fibers about the entire margin of the preparation. These fine fat droplets are present in sufficient amount to speak of an extensive diffuse fatty degeneration of the muscle fibers. Where the large fat cells have separated the muscle fibers, these are found to be more atrophic than those in the central portions of the larger bundles.

The examination of the section through the healed bullet wound on the chest walls reveals nothing of importance. The dissolution of continuity is filled in by granulation-tissue, and there is evidence of beginning restoration of the epithelium from the margins. Stains for bacteria give negative results.

In summing up the macroscopic and microscopic findings of the autopsy, the following may be stated: The original injuries to the stomach-wall had been repaired by suture, and this repair seems to have been effective. The stitches were in place, and the openings in the stomach-wall effectually closed. Firm adhesions were formed both upon the anterior and posterior walls of the stomach, which reinforced these sutures. The necroses surrounding the wounds in the stomach do not seem to be the result of any well-defined cause. It is highly probable that they were practically terminal in their nature, and that the condition developed as a result of lowered vitality. In this connection there is no evidence to indicate that the removal of the omentum from the greater curvature and the close proximity of both of these wounds to this point, had any effect in bringing about the necrosis of the gastric wall, although circulatory disturbances may have been a factor. The fact that the necrotic tissue had not been affected by digestion strongly indicates that the necrosis was developed but shortly before death. The excavation in the fat behind the stomach must be largely attributed to the action of the missile. This may have been the result of unusual rotation of a nearly-spent ball, or the result of simple concussion from the ball passing into a mass of soft tissues. Such effects are not unknown. The fact that the ball grazed the superior aspect of the left kidney, shown by the microscopic investigation of that organ, indicates the direction of the missile, which passed in a line from the inferior border of the stomach to the tract in the fat immediately superior to the kidney. There was evidence that the left adrenal gland was injured.

The injury to the pancreas must be attributed to indirect, rather than direct, action of the missile. The fact that the wall of the cavity is lined by fibrin, well advanced in organization, indicates that the injury to the tissues was produced at the time of the shooting. The absence of bacteria from the tissues indicates that the wound was not infected at the time of the shooting, and that the closure of the posterior gastric wound was effectual. The necrosis of the pancreas seems to us of great importance. The fact that there were no fat necroses in the neighborhood of this organ indicates that there was no leakage of pancreatic fluid into the surrounding tissues. It is possible that there was a leakage of pancreatic fluid into the cavity behind the stomach, as the contents of this cavity consisted of a thick, grayish fluid, containing fragments of connective tissue. In this case the wall of fibrin would have been sufficient to prevent the pancreatic fluid from coming in contact with the adjacent fat. The extensive necrosis of the pancreas would seem to be an important factor in the cause of death, although it has never been definitely shown how much destruction of this organ is necessary to produce death. There are experiments upon animals upon record, in which the animals seem to have died as a result of not very extensive lesions of this organ. One experiment of this nature reported by Flexner (*Journal of Experimental Medicine*, Vol. II) is of interest. The fact that concussion and slight injuries of the pancreas may be a factor in the development of necrosis, is indicated by the researches of Chiari (*Zeitschrift fuer Heilkunde*, Vol. xvii, 1896, and *Prager Med. Wochenschr.*, 1900, No. 14), who has observed (although a comparatively rare condition) extensive areas of softening and necrosis of the pancreas, especially of the posterior central portion which lies directly over the bodies of the vertebræ, where the organ is most exposed to pressure or the effects of concussion. The wound in the kidney is of slight importance, except as indicating the direction taken by the missile. The changes in the heart, as shown by the macroscopic inspection and the microscopic examination, indicate that the condition of this organ was an important factor. The extensive brown atrophy and diffuse fatty degeneration of the muscle, but especially the extent to which the pericardial fat had invaded the atrophic muscle fibers of the right ventricular wall, sufficiently explain the rapid pulse and lack of response of this organ to stimulation during life.

REPORT ON THE BACTERIOLOGIC EXAMINATION.

BY

HERMAN G. MATZINGER, M.D.

Bacteriologist to the New York State Pathological Laboratory.

It is obvious that the short space of time which has elapsed since the death of the President has hardly been sufficient to prepare a complete and thorough bacteriologic report. This report contains all the observations which have been made up to this time:

On September 11, during the life of the President, cultures were made by Dr. Wasdin from the base of the abdominal wound and from dressings removed at the same time. These were submitted to me for examination, and showed the presence of the ordinary pus organisms: Staphylococcus pyogenes aureus and S. cereus albus, with a gas-forming bacillus which, in pure anaerobic culture on glucose gelatin, forms small, pearly, translucent colonies, with no liquefaction. In litmus milk it produces acid, but no coagulation. Morphologically, it is apparently a capsulated, short bacillus, which takes stains poorly, and which does not stain by Gram's method. Inoculated into the ear vein of a rabbit, which was killed immediately afterward, it produced, after 24 hours in the body of the rabbit, a marked accumulation of gas in the organs, and again grew out in pure culture. As yet the organism is not fully identified.

None of these cultures showed streptococci. A bacterium which appears to be one of the proteus group was, however, isolated, which does not stain by Gram, and appears in varying forms, sometimes small oval, and again quite rod shaped and in short chains. Sometimes it is surrounded with a slimy covering, which remains clear like a capsule when the organism is stained. On slanting agar, it produces a whitish, slimy growth, which gradually runs to the bottom of the slant and produces an odor of decomposition. On gelatin, it grows very slowly with slight and slow indication of liquefacton. In litmus milk, it produces acid and rapid coagulation.

At the time of the autopsy, September 14, inoculations were made by myself. From the base of the wound, there was again obtained a number of pus organisms, principally a white staphylococcus and the bacterium described above, but no streptococci. Cultures made from the peritoneal surface of the intestines were entirely negative. Cultures made from the under surface of the omentum near the colon, were entirely negative, both with and without oxygen. Cultures from the blood of the right auricle were likewise negative. A very careful and extensive search for micro-organism in the contents of the necrotic cavity, behind the stomach, reveals nothing but a short stumpy bacterium, which, as far as the work has been carried at present, appears to belong to the proteus group, *and is very like* Proteus hominis capsulatus, described by Bordoni and Uffreduzzi.

Morphologically, it is not uniform, and sometimes appears almost encapsulated, being surrounded by material that does not stain; is quite refractory to Gram, and produces an odor of decomposition as it grows. It does not liquefy gelatin rapidly and grows slowly, as a glistening white elevated surface growth which slowly sinks; but on agar in the thermostat it grows very rapidly, as a moist, grayish-white, translucent mass. Colonies on gelatin plates have a clean circumference, are granular and quite refractive. In litmus milk it produces acid and rapid coagulation. Animal experiments are still incomplete and can not be published at this time.

It must be stated that there is occasion for suspecting that this may be a contamination, either from the outer wound or elsewhere, because, quite unavoidably, the technique of obtaining the material and cultures from the necrotic cavity was not absolutely correct.

Cultures made from the small area of broken-down tissue under the chest wound at the time of the autopsy, grew what appears to be staphylococcus epidermidis albus, described by Dr. Welch.

The slimy, gray, necrotic material from the cavity above the transverse mesocolon behind the stomach, was carefully examined microscopically, with the result that very few micro-organisms were found in the fresh state, and no recognizable tissue elements of any kind, no leucocytes or pus-corpuscles, but an abundance of crystals which appeared more like fatty acid than fat crystals. It contained no free hydrochloric acid, and was alkaline in reaction. Experiments as to its digestive power were negative. About 2 cc. of this material were injected into the space behind the stomach of a dog (still living), with no result except quite an elevated temperature for 3 or 4 days. Other animal experiments are also still incomplete.

It might be well to state here that the bacteriologic examination of the chambers and barrel of the weapon used, as well as the empty shells and cartridges, ordered by the District Attorney, was entirely negative, except that from a loaded cartridge there was grown an ordinary staphylococcus and a mould. The chemical examination of the balance of the loaded cartridges, made by Dr. Hill, chemist, was also negative.

The absence of known pathogenic bacteria, particularly in the necrotic cavity, warrants the conclusion that bacterial infection was not a factor in the production of the conditions found at the autopsy.

This report has received the approval of the consulting staff of the late President, and is issued with our consent.

Clinical Report.

TRACHEOTOMY IN BREECH PRESENTATION.

AN OLD OPERATION BUT A NEW APPLICATION.

HERBERT MARION STOWE, M.D.
Demonstrator of Operative Obstetrics, Northwestern University Medical School; Assistant Obstetrician to Provident Hospital.
CHICAGO.

Mrs. E. M. C., German, aged 31, was taken in labor with her second child at 12:30 p. m., Sept. 1, 1901. I was summoned at 10 o'clock on the evening of the same day. Upon my arrival at the house, I found a nervous and delicate woman in the second stage of labor. I diagnosed a breech presentation, S. D. A.; the breech being high up and not engaged. The membranes had ruptured early, and the birth canal was poorly prepared for fetal passage. The fetal heart tones were regular, but numbered 160 beats per minute. The fetus was unusually active. The pains were weak and of short duration. By reason of the danger of fetal asphyxia, I proceeded to extract.

It was impossible to bring down a foot, but I succeeded in placing a finger in the anterior groin and made pressure downward and backward in the usual manner until the posterior groin was within reach. After this point, the first act of extraction was easy and was quickly completed. No further difficulty was experienced until after the arms had been delivered. The head had become fixed in the transverse diameter of the inlet and remained so in spite of the Smellie-Veit's, or, more correctly speaking, the Mauriceau method combined with strong suprapubic pressure in the Walcher posture. After working a short time, however, the head was felt to descend slightly into the pelvis, while the occiput partially rotated anteriorly, but successful extraction of a living child seemed impossible at the time.

Convinced, therefore, that the child's life was practically lost, the writer decided to perform tracheotomy as an experimental operation. The body of the child was lifted up by an assistant, the neck hastily washed with a one-half per cent. lysol solution, and the field of operation rendered as aseptic as the limited amount of time would permit. The perineum was pressed backward and the larynx was then steadied with a tenaculum and a linear incision made through the cricoid cartilage, and two or three rings of the trachea. The thick, venous blood which escaped from the incision gave positive evidence of the grave state of asphyxia present. The tissues were then retracted and a soft rubber, aseptic, tracheal catheter was introduced far enough to snugly fit the trachea and pure air gently forced into the lungs by an air-bag. The lungs immediately expanded and the chest was then compressed by the hands. These movements, alternating, were continued until the respiratory rhythm was voluntarily inaugurated and maintained and the body became pink in color. The hemorrhage now ceased and forceps were applied to the after-coming head; stationary, intermittent tractions were made and every effort taken to preserve the perineum as far as possible. In fourteen and one-half minutes after the delivery of the arms, the head was extracted and the child born without any sign of the asphyxia which was so threatening a short time before. The child's body was wrapped in a warm, moist towel to prevent premature respiration during extraction.

The cord was left uncut until the funic circulation ceased and the loss of blood from the neck was in a measure compensated for. The mouth and throat were cleansed and the blood in the trachea carefully removed. Respiration took place through the laryngeal opening only. The child uttered a few weak cries when slapped, but otherwise appeared healthy. A stitch was taken on each side of the incision and the long end of the threads tied behind the neck. This kept the incision patulous and allowed free access of air when the catheter was withdrawn.

Five hours later, there being no dyspnea when the wound edges were coaptated, sutures of fine catgut were introduced and tied, and thus normal respiration was established for the first time. The wound healed by first intention and the child made an excellent recovery. The temperature was at no time over 102 F. The mother recovered with an intact perineum.

The fetal measurements were as follows: Diameter, bitemporal, 8 cm.; biparietal, 8.5 cm.; suboccipital-bregmatic, 9.5 cm.; occipital-frontal, 11 cm.; occipito-mental, 12 cm.; bis-acromial, 10.5 cm.; bis-iliac, 8.5 cm. The cephalic bones were hard and ossified; the fontanelles small; the sutures closed.

The mother's diameters were: Interspinous, 25 cm.; intercristous, 27.5 cm.; Baudelocque, 18 cm.; bitrochanteric, 31 cm.; circumference, 92 cm.; conjugata vera, 9 cm.

It has long been an established rule in obstetric practice to extract the fetal head as quickly as possible in head last cases. The fetus at this stage of the operation is deprived of its supply of oxygen by the cord being caught between the head and the maternal pelvis, or, as is claimed by some writers, a partial separation of the placenta from the uterine wall. The amount of oxygen already in the body is only sufficient to retain fetal life for four or five minutes, although cases are recorded where children have been resuscitated after fifteen minutes of delay. These cases, however, are exceptional, and their accuracy is sometimes questioned. Time is the greatest element in the safe delivery of the fetus after the cord has come into view. If the head is not delivered within four to six minutes after the extraction of the arms the child will probably be still-born or else deeply asphyxiated.

Attempts have been made to prevent asphyxia by supplying the child with oxygen artificially during extraction. Pugh recommended the method of passing two fingers into the mouth and allowing air to enter along the hollow of the hand. Weidmann conveyed air to the mouth by means of a catheter or a special tube prepared for the purpose called the "vectis aerophorus." When the head is low in the pelvis, the perineum can frequently be pushed behind the mouth and air admitted to the oral cavity directly. Where, however, the mouth is beyond the reach of the fingers and the catheter becomes useless on account of the difficulty of entering the mouth and the inevitable kink at the bend of the tube, the only chance of saving the child's life has, heretofore, been in a rapid forceps operation with a large fetal mortality resulting. Should the forceps operation prove negative, the child immediately dies, or craniotomy, with a mortality of 100 per cent., follows. Should the forceps deliver the child, it is deeply asphyxiated and frequently, because of premature respiratory efforts, becomes a victim of aspiration pneumonia.

In a given case where the estimated diameters of the fetal head and the determined diameters of the pelvis are such that the accoucheur may expect cephalic impaction; where the usual methods by hand and position have proven fruitless the operation of tracheotomy as described above is recommended. When the child's body is raised to a perpendicular plane, the blood and mucus are prevented from clogging up the bronchi. In a majority of the cases the proximal end of the trachea will be found free of obstruction as the mucus collects principally in the pharynx and upper larynx. The use of an air-bag, such as the Politzer inflation bag, is preferable to blowing in air from the lungs, as expired air is always deficient in oxygen. If one were able to introduce nearly pure oxygen gas, the child would stand the best chance for recovery. The body should be enveloped by a warm, moist towel, to reduce to a minimum the difference between the internal and external atmospheres.

If the labor has been conducted according to established rules of asepsis and antisepsis, little or no time need be lost in cleansing the neck as the fetus is already sterile unless infected from external sources.

With the imminent danger of asphyxia forestalled, the forceps may be applied to the after-coming head and traction be slowly made, giving time for the head to mold and adapt itself to the pelvic canal as well as protecting the perineum as far as possible. This method is to be preferred to the common one of applying forceps, extracting hastily and in 28 to 30 per cent. of cases delivering a dead child, besides in many cases lacerating the perineum. Should the perineum be found to overlap the neck to a moderate extent, an episiotomy may be done immediately, and the tissues retracted sufficiently to expose the field of operation.

The after-treatment is carried out in the usual manner. The obstruction to respiration being removed at birth, the tracheotomy wound may be closed in a few hours.

4433 Lake Avenue.

Diet in Nephritis.—A nephritic must be well nourished, and the old theories of the harmfulness of this or that food are not sustained by actual experience. It may even prove possible that creatin and similar substances may be directly beneficial, on the same principle as we treat heart diseases with heart poisons. O. Reichel publishes in the *Cbl. f. d. Ges. Ther.*, January, a study of the subject, concluding that the nephritic patient should not be restricted in diet, but should be allowed to eat whatever he best digests and assimilates, without regard to theory. He urges closer study of the mild, ambulant cases of albuminuria, partial nephritis and post-nephritic inflammation of the kidneys—regarding them all as actual nephritis and better suited than severer cases for research on the effect of diet on the progress or retrogression of the morbid processes. He also denounces sweat baths as another purely theoretical measure, which in reality fails to accomplish the anticipated results. He has never known a nephritic to be benefited by them in his experience. He attributes the symptoms in nephritis to a toxin in the blood, retained by the insufficiency of the kidneys, and causing the edema and hypertrophy of the heart by the changes it induces in the kidneys, which diminish their power of resorption. Insufficient absorption is a factor in the delay in the test-elimination of methylene blue, as well as the insufficiency of the kidneys. The changes in the walls of the vessels cause increased resistance, and, secondarily, increased blood pressure with consequent hypertrophy of the heart.

SATURDAY, OCTOBER 19, 1901.

RUDOLPH VIRCHOW.

Professor Rudolph Ludwig Karl Virchow, the distinguished German pathologist, anthropologist and politician, completed his eightieth year on Sunday, October 13, 1901. The event was celebrated in Berlin and in most of the medical centers of the world on Saturday, October 12.

Virchow was born in Schivelbein, a small town in Pomerania, in 1821. He was educated at the Gymnasium in Berlin, and graduated in medicine at the University in that city in 1843. After graduation he undertook the study of pathology and soon became assistant to Froriep and prosector at the Charité. With his friend Reinhardt, he founded in 1847 the *Archiv*, which has become the most important medical periodical in the world and ever since has borne his name. Compelled in 1849, on account of his democratic tendencies, to give up his position and residence in Berlin, Virchow removed to Würzburg, where he continued active work in pathological anatomy, supported the Physikalische-Medicinische Gesellschaft, and made for himself such a name that the faculty and government in Berlin recalled him in 1856 to the Chair of Pathological Anatomy. A new pathological institute was established for him, and he has remained director of this institute and professor of the University ever since.

To understand Virchow's immense influence upon the progress of medicine it is only necessary to compare the conditions of the science before 1850 with those which exist to-day and to recall briefly the various researches undertaken by Virchow during the intervening period. Before the time of Virchow's work, accurate autopsy reports were scarcely known. Clinical histories of patients were reported from memory rather than from notes taken at the time of the examinations, and even when clinical records were made they referred only to the pulse and to a few of the more striking symptoms. Nearly all medical articles were made to conform to some abstract theory, or were arranged according to some one of the "systems" so much in vogue in the eighteenth and the first half of the nineteenth centuries. In the program laid down in the first volume of the *Archiv* (1847), Virchow declared that the time had come for the detailed study of individual cases, pathological and clinical. Only after the accumulation of such data did he believe that it would be possible to construct a true theory of disease—a pathological physiology of real value. General laws were to be arrived at from below rather than from above; hypotheses were to succeed rather than precede the establishment of such general laws; thenceforward the inductive, not the deductive method, was to be the dominant one in medicine. It was necessary, he declared, that in the study of medicine we get at least three hundred times nearer than in the past to the natural processes.

The enemies of the new movement declared that Virchow was not practical; that his ideas were dangerous, and that he and his comrades were doctrinaires and adventurers. The fight started by the *Archiv* against the prevalent mixture of voluntary rationalism and gross empiricism proved, however, rapidly successful, and the introduction by Virchow of the genetic principle of investigation did much to turn pathological studies in an entirely new direction.

Among pathologists Virchow, though revered for his special researches on pyemia, leukemia, thrombosis and embolism, is perhaps best known as the founder of the so-called "cellular pathology." In his now long-famous volume (Die Cellularpathologie in ihrer Begründung auf physiologischer und pathologischer Gewebelehre, Berlin, 1858) he led back pathological processes in greater completeness than had ever been attempted before, to alterations in the elementary constituents of the body—the cells. His great work on tumors (Die Kranhaften Geschwülste, Berlin. 1863-67) remains to-day the most valuable work on the subject for consultation. The technique introduced into the autopsy-room by Virchow and his published account of it became the standard for postmortem work all over the world.

In anthropology and ethnography Virchow is as well and favorably known as in pathology. His investigations of race characteristics, his measurements of skulls and other contributions in the fields are epoch-marking.

Virchow's fame quickly spread beyond his own country; students of higher medicine flocked to him from all parts of the world, and he speedily became the head of the school of pathology known by his name. His power as a teacher has been unrivaled. He knew how to excite in his pupils the spirit of investigation.

No greater compliment has, perhaps, ever been paid to a scientific medical man than that made in honor of his seventieth birthday, when fifty-four of the most prominent medical scientists in the world contributed three large volumes of original research to his Festschrift. [Internationale Beiträge zur wissenschaftlichen Medicin. Festschrift. Rudolph Virchow, gewidmet zur Vollendung seines 70 Lebensjahres. 3 V. roy. 8°. Berlin, 1891]. His international reputation was no doubt largely due to his winning personality and literary power as well as to his investigative talent.

One of the most pleasing of the many praiseworthy features of Virchow's life is the humanitarian side of his work. Beginning with his investigations on famine fever among the poor inhabitants of Upper Silesia, in 1848, Virchow has always given largely of his energies and his interest to the promotion of the welfare of the masses. His contributions to the science of public hygiene are among the most notable of his works. Among them may be mentioned his articles on the drainage and sewage disposal of the city of Berlin, his various papers on military hygiene, on school hygiene, on the German household, and on disinfection. He made a special study of the best forms of exercise for the development of German youth. He has always been friendly to the higher education of women. For many years he has occupied a seat in the Reichstag and has taken a most active part in the government in connection with medical and veterinary affairs.

In his relations to life in general, as well as in practical politics, he has remained consistently a pronounced democrat. While a loyal German, he is a devotee of the cult of humanity. A citizen of the world, he does not belong to any one country.

Virchow has this year been especially honored by the Emperor of Germany and the King of Italy. The medical men of the civilized world have vied with one another in paying him homage. His life is an illustrious example of what a great man may accomplish by devoting his talents, time and energy to the scientific side of medicine. The results of his work and the remarkable personality of the man have made many others attempt to follow in his footsteps; a public need for workers in pathology has gradually developed until to-day pathology affords a career for many of the best men in our profession. Rich men are giving large sums of money toward medical research and the outlook for the future of pathology is bright. To none other of his age has it been vouchsafed to do more in the reshaping of medical thought and opinion than Rudolph Virchow.

CELLULAR PATHOLOGY IN THE PAST AND IN THE FUTURE.

It will not be amiss, at this time of celebrating the eightieth birthday of Virchow, to call attention to the fact that a new era in medicine began in the middle of the last century when the cellular structure of living organisms and of many pathological products became understood. The era was introduced by the demonstration of the cellular structure of plants by Schleiden, in 1838, and of animals by Schwann, in 1839. The rich fields of investigation thus thrown open for cultivation were soon appropriated by eager German investigators, and pre-eminently by the now so venerable Virchow and his numerous and enthusiastic pupils. Virchow may be said to have begun his work in 1840, and in a remarkably short time he not only made an end to the domination of medicine by the unfounded conceptions of the old humoral pathology, which had held sway for some two thousand years, but he also laid the foundations of a new pathology, the cellular pathology, upon the basis of which a mighty superstructure has been built. This was accomplished partly by destructive criticism of the old doctrines of dyscrasia, partly by showing that cellular proliferation never takes place from unorganized blastema, but only from pre-existing cells. The famous phrase of 1855, *"Omnis cellula e cellula,"* sounded the death-knell of the old humoral pathology and the birth of the new, cellular pathology.

As stated elsewhere, Virchow is the founder of pathological histology. He demonstrated that as all normal tissues consist of cells, so do cells play the essential part in pathological tissues and pathological products, and he traced the processes of disease to cells and to cell families. This is the kernel of the cellular pathology as it is developed in his celebrated lectures in Berlin in 1857 on "Die cellulare Pathologie in ihrer Begründung auf physiologischer und pathologischer Gewebelehre."

Of fundamental importance to the development of cellular pathology and of modern medicine as a whole is Virchow's masterly organization of the teaching and the investigation of pathological anatomy, which resulted in the establishment in Berlin and later in connection with all German universities of the pathological-anatomical institutes, or laboratories, which the whole medical world long ago has come to recognize as indispensably necessary for teaching and research in medical science. His official report setting forth the essential necessity and the scope of such establishments with the various subdivisions, such as the chemical laboratory, the pathological museum, although written in 1846, might well serve as a guide for many institutions in this country that now are beginning to plan in real earnest the foundation of medical departments upon a permanent basis commensurate with their importance. Fortunately this report is within easy reach as it is printed in Virchow's *Archiv,* 1900, clix, pp. 24-39. In this report Virchow can not sufficiently emphasize the weight that should be placed upon pathological physiology.

Under the leadership of cellular pathology many have thought—and probably with good reason—that the study of pathological histology has been carried too far. Because some of its followers seemed to think that they could reach the innermost secrets of disease by morphological methods, they did not hesitate to utilize histologic structure as the principle of classification and subdivision of pathological processes. This one-sided overestimation of the results of microscopic examination, valuable and important though they may be; the failure to recognize the greater importance of etiology, which is seen in some of the teachings of the Virchow school in regard to inflammation, e. g., the dualistic doctrine of tuberculosis; as well as the comparatively few directly valuable results in practical therapeutics, have tended to bring a measure of discredit upon cellular pathology. But this tendency to overestimate cellular pathology in the narrow sense is being counterbalanced by the brilliant discoveries in bacteriology and the great progress in the knowledge of the causes of disease of more recent times. Pasteur's demonstration that infectious diseases are caused by micro-organisms inaugurated a still newer era in medicine with developments of fundamental import for pathological anatomy and all other branches of medical science.

That the cellular hypothesis has helped greatly to elucidate the phenomena of life both under physiological and pathological conditions no one would gainsay, but it must not be forgotten that forms are inseparably connected with and dependent upon questions of force—"every form is force visible"—and cells are, as Huxley has it, not the cause but the results of organization and therefore not the only and ultimate object of biologic investigation. Virchow himself has said that the trained pathological anatomist can not deal with the product without searching for the mechanism through which it has resulted, and for the conditions under which the vital processes have suffered this or that deviation in their course. The essential significance of physico-chemical processes in biological phenomena is becoming daily more manifest. The study of the forces that lie behind structure and form—the rôle in physiological and pathological processes of molecules and ions, of enzymes, of osmotic pressure, of chemical equilibrium, and other factors—is about to erect a molecular pathology by the side if not in the place of the cellular pathology that now so largely governs our conceptions of disease. Indeed, it is along physico-chemical lines that we must look for the explanation of many phenomena, normal and abnormal, phenomena the existence of which may be made known but not explained by morphologic methods. And it is probably in this field that the present century will bring its farthest reaching achievements in physiology and pathology.

OFFICIAL REPORT ON PRESIDENT M'KINLEY'S CASE.

We publish this week the official report on President McKinley's case, signed by all the attending physicians and surgeons. It is very complete even to minor details, and a careful reading must convince the most critical that the case from the beginning was well managed and that no adverse, retrospective criticism is possible. The report shows that the charges as to poor judgment used in the administration of solid food, in failure to find the bullet both during the original operation and at the autopsy, in the non-use of the *x*-ray and of drainage, can not be sustained. The main interest of the report centers in that which pertains to the autopsy and the examination and deductions therefrom. This part of the report is the important part of the document, as it is bound to excite interest not only because of its disclosures, but as well because of what it fails to disclose.

In the case of the wounds of the stomach effective closure had been secured by means of stitches which had become re-enforced by adhesions both anteriorly and posteriorly. Both wounds were found surrounded by areas of discolored and softened tissue which had lost its microscopic structure. The cause of this change is not at all evident. In his summary the pathologist suggests its terminal nature and the cause as lowered vitality. It appears hardly necessary to offer an explanation of so general character as "lowered vitality."

There seems to be no essential reason why these changes may not have resulted from the action of the gastric juice and that they were of the nature of postmortem digestion. The area of discoloration on the surface of the mesocolon which came directly in contact with the wound on the posterior gastric wall was of a dull gray color, indicating a diffusion into it of the same substance or substances as may have caused the discoloration and softening in the tissues about the wounds in the stomach. There is no statement in the report of the condition of the interior of the stomach; it is not mentioned whether or not the stomach was opened; and it is unfortunate that opportunity was not given to freely examine the areas about the wounds by means of a large number of microscopic sections extending freely across the entire area including the stitches. Bacteriologic examination of the tissue about the wounds, either by culture or by the staining of sections, is not mentioned in the report; hence the influence of bacteria that possibly may have been present can not be excluded altogether. At all events the changes found immediately about the wounds in the stomach do not appear to have had any recognizable influence at all upon the fatal ending.

The pancreas contained "numerous minute hemorrhages and areas of gray softening, the size of a pea or smaller." As stated in the report the absence of fat necrosis shows that there was no diffusion of pancreatic ferments into the surrounding tissues, except possibly into the cavity behind the stomach. It is particularly unfortunate that a more thorough examination could not have been made of the pancreas. The lesions described can not be regarded otherwise than as of significance, but in the absence of both bacteriologic and histologic examination their exact cause and nature remain conjectural. It is very easy to suggest that the foci of softening in the pancreas may have contained bacteria whose products when absorbed gave rise to serious general effects. We lack information also as to the nature of the greenish-gray thick fluid, a few teaspoonfuls of which ran out into the peritoneal cavity from "a point just beneath the mesocolon," and which does not seem to have come from the cavity behind the stomach.

The destructive fatty infiltration of the walls of the right ventricle will be found generally acceptable as explaining at least in part the character of the action of the heart during life. The diffuse fatty changes of the heart muscle fibers proper will most likely be regarded as the result of some form of intoxication.

The bacteriologic examination, though not yet completed, seems to exclude the presence of "known pathogenic agents," at least in the track behind the stomach and in the general peritoneal cavity. But cultures were not made from the spleen, the liver, the kidneys, the lungs, or the pancreas. Cultures (presumably only aërobic) from the heart's blood remained sterile. Staphylococci and an unidentified anaërobic, gas-forming bacillus were isolated from the abdominal wound, both during life and after death, but the question of their actual general pathogenic influences will probably be open to various interpretations.

The absence of any mention in the report of the actual condition of the adrenals, the interior of the intestines, etc., and the lack of sufficient material for extended further investigations, as well as the failure to find the bullet, are plainly attributable to circumstances over which the pathologists had no control. While the circumstances under which the autopsy was made prevented the thorough, all-embracing examination that would have been necessary to throw the fullest light upon the many and complicated problems in the case, enough was learned to place the surgical treatment above all criticism of even the most censorious scrutinizer.

THE HEALTH OF THE ARMY.

The report of the Surgeon-General of the Army, which has just been received, contains some interesting details. Notwithstanding the fact that the active service of the Army is in the tropical regions, which are generally supposed to be more trying in a sanitary point of view than temperate ones, its general health for the year 1900 has been excellent. The higher rates of mortality were among the volunteers in the Philippines, thus showing that this type of service has its disadvantages from a sanitary as well as from other points of view. In Cuba the mortality ratio for 1900 was little more than one-half that of the preceding year and, but for the occurrence of yellow fever, would have been still further reduced. There were 144 cases of this disease, of which 32 were fatal. In Porto Rico the death-rate was the lowest, 5.05 per 1000, ever recorded in the army. This may perhaps be in part accounted for by the fact that a portion of the troops there belong to the native regiment and, besides being thoroughly acclimated, are probably placed under better sanitary conditions than even before their enlistment. It points, nevertheless, to the fact that Porto Rico has a healthy climate for a tropical possession. The largest death-rate naturally was in the details for Chinese service and most of this from casualties of active service.

Since the close of the calendar year 1900 the health of the troops in the Philippines has been steadily improving, and the decrease has been noted not merely in the non-efficiency from disease, but also in that from injuries. From January to June, 1901, the non-efficiency was less than 7 per cent., which is certainly a fair showing for the tropics. Smallpox, which was a serious matter in the early occupation of the islands, has been almost entirely suppressed; typhoid fever appears now only sporadically, and bubonic plague which has prevailed among the Chinese and Filipinos has given no anxiety whatever to the army medical authorities. Malaria and dysentery have exceeded the average of the past in all sections and have particularly prevailed in the Philippines, especially among the volunteers during 1900.

Venereal diseases were a cause of inefficiency to an increased extent in all sections, Porto Rico taking the lead, where the excessive ratio of 367.88 was recorded; in this it approached the British Indian army figures. In the volunteers in the Philippines the average (79.94) did not very greatly exceed the army average for the decade 1889-1898 before the Spanish war (71.45). Alcoholism, on the other hand, appears to be decreasing, the admission rate from this cause for the whole army during 1900 being 15.34 as compared with 28.67 per 1000 in the pre-Spanish war decade. This is perhaps partly due to a better grade of men in the service; Dr. Sternberg credits it to the establishment of the canteen, which he thinks induces to temperance. Here, also, the volunteers in the Orient showed to advantage with their ratio of only 8.68, as compared with the 12.41 of the regulars; but both are well below the general army average. Our troops in China gave a still lower figure, and the record of troops in insular and foreign service generally does not justify some of the sensational statements that have been sent out by portions of the public press.

The yellow fever investigation in Cuba and the excellent work done by the army in the study of tropical diseases in the Orient are duly mentioned. The former alone is sufficiently important in its results to make the year memorable in the history of medicine as well as in the army records. The researches in regard to dysentery and other diseases of the tropics, while less striking in their results so far, are hardly less important and it is satisfactory to note that our army medical department is doing such good work in these directions. The report gives data in regard to the personnel, and it appears that the medical corps is gradually filling its vacancies, but there has still to be a large force of contract surgeons employed. Many of the successful candidates for commissions were from this class, which seems, therefore, to be, in a way, an army medical school. It is a pity, however, that in times of nominal peace the army medical corps is still so restricted by law as to make the employment of contract surgeons necessary.

CONTROL OF LEPROSY.

The Molokai leper settlement, according to reports, is decreasing in population. Five years ago there were 1300 lepers, while now there are barely 900. The general cleaning out of the lepers from the other islands and their transference to Molokai since the downfall of the Hawaiian monarchy, has affected the source; there are fewer cases of the disease among the general population, and, therefore, less chance of its spread. Last year an even hundred lepers were sent to the settlment; thus far in the present year not much over 50 have been found to recruit its waning membership. Since annexation still stricter rules have been adopted and it seems probable that we may soon see this famous aggregation of this most loathsome disease become insignificant as compared with its past. There is a chance for another to take its place, however, in the Philippines where the lepers, it is said, number many thousands and where there has been practically no attempt whatever to segregate them thus far. In Hawaii leprosy appears likely to be helped along in its decadence by the dying out of the native race, but this is hardly likely to be the case in the Philippines. Whether, with thorough means of isolation and prevention, it can be altogether eradicated in the tropics is one of the chief medical problems of the future.

NEW YORK STATE MEDICAL ASSOCIATION.

The next meeting of this Association will be held in New York City, October 21 to 24, and promises to be one of the largest in the history of that Association. The program is an excellent one and can not but attract an attendance, not only from Greater New York but from the whole state. This Association now has over 1600 members in good standing. Its rapid growth under the new Constitution can be appreciated when it is understood that over twenty new county associations have been organized during the past year.

LOOKING BACK.

On the fifth of this month our esteemed contemporary, the London *Lancet*, celebrated its seventy-eighth birthday by reprinting the leading editorial in the initial number of that journal. The first issue was dated October 5, 1823, and the present editors propose to reprint each week a selection from the corresponding number of seventy-eight years ago. It seems strange that in the pious city of London a weekly medical journal such as the *Lancet* should have appeared dated Sunday and not Saturday, but such is the fact, and for some months the issuing date was Sunday. If the selections to be made show the vast advance in medical knowledge in the last seventy-eight years they will certainly be interesting, if not instructive. The first editorial is really a preface or announcement, but the editor makes no apology for the appearance of a medical weekly. "It has long been a subject of surprise and regret, that in this extensive and intelligent community there has not hitherto existed a work that would convey to the Public, and to distant Practitioners as well as to Students in Medicine and Surgery, reports of the Metropolitan Hospital Lectures," is the first paragraph. Attention is called to the lectures then being delivered by Sir Astley Cooper of St. Thomas' Hospital, and these are referred to as being the best of the kind delivered in Europe. The first, or introductory lecture, by Sir Astley Cooper, appeared in the first number of the *Lancet*. It was the printing of the metropolitan hospital lectures which, later on, got the *Lancet* into so much trouble, the lecturers protesting at having their private lectures, through which they made money, become public property. Evidently the views held by Mr. Wakly as to the functions of his new weekly were a little vague, for in the concluding paragraph of his editorial he says that, "we shall be indefatigable in our exertions to render the *Lancet* a complete Chronicle of Current Literature." We shall await with curiosity and interest for the forthcoming excerpts from the early numbers of the oldest medical weekly in the world.

MILK SUPPLY IN NEW YORK.

Milk is one of the most important of human foods and also one most liable to contamination between the producer and the user. Hence the complexity of the question as to a pure milk supply and the special interest to the profession of a recent report that has just been given out, by a commission of New York physicians, of which Dr. Henry Dwight Chapin is the head. The method adopted was to establish a bacterial standard of marketable milk, making the bacterial contents per cubic centimeter the index of purity. The leading milk-dealers were invited to co-operate and some of them have apparently aided materially in the investigation, adopting the suggestions made by the commission and showing generally a readiness to carry out what measures were necessary. The need of such was made sufficiently evident by the first test of milk taken directly from the dealers on a mild November day, when the bacterial contents of the samples ranged from 13,000 to 2,800,000. On a warm June day the following summer in six samples taken at random it ranged from 520,000 to 216,000,000. These are mentioned as from the better grades of milk used in New York. Over eight hundred bacteriologic examinations were made and some thirty visits to dairies, some of them a distance of 180 miles from the city. The condition of the barns, the cows, the milkers, the utensils, cooling processes, and transportation and the condition of the cans or vessels when returned from users were all taken up and studied in detail. Each of these was found an important factor, the mere fact of a pile of dry feed left near a cow making in one instance a difference of nearly a million germs in the milk per cubic centimeter. On the other hand, with due care as to all these points, the microbes could be reduced to a few hundreds or thousands and well within the limit of 30,000 per cubic centimeter established as a standard. The commission found that young single men, being less liable to carry infection from home, were preferable as milkers and it was advised that they be clean shaven. Nothing is said about milkmaids, but it would appear that a return to the ways of former times in this regard might furnish the ideal—sanitary as well as esthetic. Much importance is given to the methods of äerating and cooling as well as to the care of bottles or cans after delivery. It is easy to see how one sinner in this respect can destroy much good and neutralize all the care of his predecessors. The work has had its educational value and in every case the dealer has been able to reach the standard of the commission without great expense by following directions. Many who have not before co-operated are now making the required changes and asking for the certification of their product. The commission furnishes a special label for certified milk, which is a guarantee of its purity to the purchaser. Of course, it does not always follow that bacteria in milk are necessarily always deadly, but they have no business there in great numbers and the given test is probably the best that can be devised for the wholesomeness of the milk. This investigation has demonstrated that with proper care they will be absent, and has shown a way to insure the public against very obvious dangers. It suggests, also, other ways in which our profession can protect the public health and make for sanitary righteousness.

Medical News.

CALIFORNIA.

Huntington House a Hospital.—The San Francisco mansion of the late Collis P. Huntington, on Nob's Hill, is to be converted into a charity hospital by Mrs. Huntington.

To Examine Teachers.—The San Francisco Board of Education has appointed Drs. Henry Gibbons, Jr., and Lois Nelson to make a physical examination of the recently-elected schoolteachers.

University Medical Department Changes.—The regents of the State University have appointed Dr. Leo Newmark, now lecturer on neural pathology, professor of neurology, and Dr. Robert Orton M. Moody, assistant in anatomy.

Medical Examiners Sustained.—The application of Dr. J. J. Cowden, a graduate of the "Pacific Coast Regular College of Medicine," San Francisco, an institution held by the Board of Medical Examiners to be not in good standing, for a writ of mandamus compelling the Board to issue to him a certificate to practice medicine was denied, October 3, by Superior Judge Hunt.

Personal.—Dr. F. J. S. Conlan, Nevada City, has located in San Francisco.——Dr. Elizabeth M. Yates, Woodland, has moved to Santa Rosa.——Dr. Cephas L. Bard, Ventura, who has been critically ill, is improving.——Dr. Theo. C. Rethers, San Francisco, has been appointed chief visiting surgeon at St. Mary's Hospital, vice Dr. Alexander T. Leonard, resigned. Dr. Charles D. McGettigan, has been appointed to the visiting staff of the hospital.——Dr. John E. Purdon, Turlock, has located in Stockton.——Dr. Guy P. Corwin, Santa Monica, has moved to Pomona.

GEORGIA.

Major William D. Crosby, surgeon U. S. Army, has been ordered for duty at Fort McPherson, Atlanta.

Dr. Harry M. Clarke, Atlanta, was injured by falling into an elevator shaft, October 7, spraining his back and his ankle.

An examination for license to practice medicine in Georgia was held by the State Board of Medical Examiners at Atlanta, October 8, 26 applicants, including one woman, being examined.

Georgia Pasteur Institute.—The first annual meeting of the Georgia Pasteur Institute was held in Atlanta, October 4. Twenty-two cases had been treated; fifteen proved to have been bitten by rabid dogs, by inoculation and death of other animals. All improved under treatment and are now well.. The institute is now well established and free from debt. The following board of governors and officers were elected: Dr. Henry R. Slack, La Grange, president; Dr. James H. McDuffie, Columbus, vice-president; Dr. Charles D. Hurt, Atlanta, treasurer; Dr. Claude A. Smith, Atlanta, secretary and pathologist; Dr. James N. Brawner, Atlanta, physician in charge, and Dr. Ernest P. Ham, Gainesville; Dr. Madison M. Holland, Statesboro, Mr. Benjamin W. Hunt, Eatonton, and Mr. George C. Waters, Atlanta, governors.

ILLINOIS.

Communicable Diseases.—Typhoid fever is prevalent at Champaign. Smallpox has appeared in Neponset and Venice, Madison County.

New Peoria Hospital.—The new St. Francis Hospital, erected at Peoria, at a cost of $115,000, was thrown open to the public, October 10. The formal dedication will occur next month.

Personal.—Dr. John H. Mannon, Kewanee, returned from a six-weeks' trip to Europe, October 4.——Dr. George S. Henderson, Holcomb, has returned from a visit to Canada.——Dr. James A. Glenn, Ashland, has been appointed a member of the State Board of Charities.

Counties Must Pay Smallpox Bills.—The attorney general has rendered an opinion that counties are liable for all expenses in connection with the care and treatment of smallpox patients, with the exception of the expenses of enforcing quarantine regulations, for which expense the cities are liable.

Chicago.

Rapidly Regained Reason.—Dr. Armstrong, now undergoing sentence in Wheaton jail on account of his connection with the diploma mill frauds, petitioned recently for release from jail on account of rapidly failing mental and physical health. A marked improvement is reported to have followed the suggestion by the district attorney, that if removed from Wheaton he would be sent to the Government Insane Asylum at Washington.

Personal.—Drs. N. Senn, Daniel R. Brower and Jacob Frank landed in San Francisco, October 14, and reached Chicago three days later, from their trip around the world.——Dr. F. M. Adams, interne of Wesley Hospital, has been compelled to seek a change of climate. He has been seriously ill with pleurisy.——Major Henry I. Raymond, attending surgeon, Headquarters Department of the Lakes, has been ordered to duty in the Philippines. He will be relieved by his brother, Major Thomas N. Raymond.——Dr. G. Frank Lydston has been elected a member of the Kauai Kodak Klub of Koloa Kauia, Hawaiian Islands.——Dr. James M. Phelan, an interne in Cook County Hospital, has passed the Army Medical Board examination.

A Typhoid Fever Year.—The current Bulletin of the Health Department says that this first year of the new century promises to be a typhoid fever year. From all parts of the United States come reports of an unusual increase of the disease; in the large cities "Public Health Reports" all show more than the usual autumnal increase. In this city the record of typhoid mortality for the third quarter of the year (July, August and September) shows an increase of 273 per cent. over that of the first six months; that is, from 0.90 per cent. of the total mortality between January 1 and June 30 to 3.36 per cent. of the total mortality between July 1 and September 30. The average autumnal increase in this region is about 70 per cent., so that Chicago's fall increase this year is very nearly four times greater than usual. This enormous increase is, however, to some extent relative, owing to the fact that the typhoid mortality of the first six months of the year was the lowest on record since records have been kept—only nine-tenths of 1 per cent. of the total mortality, as against a previous average of nearly 1.6 per cent. during the previous five years.

INDIANA.

Communicable Diseases.—Smallpox is reported from Coldwater and Richmond; Vincennes has 40 cases of typhoid fever, and four cases of diphtheria are reported from North Judson.

Personal.—Dr. R. O. Tidrick has moved from Bringhurst to Marion.——Dr. H. E. Phares, Morristown, will locate in Shelbyville.——Dr. Herbert O. Statler, Goshen, has moved to Kalamazoo, Mich.

Smoke for Consumption.—Dr. George R. Peckinpaugh, Mount Vernon, is reported to have discovered that inhalation by the patient of the fumes or smoke from the burning of a mixture of various kinds of forest leaves kills the bacilli in the lungs. The Evansville Board of Health is carrying on experiments with this treatment on the consumptive patients at the County Poor-House.

IOWA.

Diphtheria is so prevalent at Reinbeck that it has been deemed necessary to close schools and churches.

An isolation hospital site at Dubuque has been offered the city by Alphonse Rhomberg, well located and with good drainage.

Bequest to St. Luke's Hospital.—Davenport is to receive a bequest of $3000 from Mrs. M. Dawes, Brooklyn, N. Y., as a tribute of respect and affection to the memory of her aunt, the late Mrs. Frances M. French, Davenport.

Personal.—Dr. W. P. Burke, Iowa Falls, leaves in December for a year's study in Europe.—Dr. F. R. King, Anita, has purchased the practice of Dr. F. C. Mitchell at Kenwood Park, Cedar Rapids, and has moved to that place.——Dr. John W. Hemsted, Carson, who has been in ill health for two years, has so far improved that he will soon resume practice.——Dr. Homer J. Gilfillan, Trenton, has moved to Mount Pleasant.——

Dr. Fred L. Wells, Des Moines, has located in Hartford City, Ind.

KENTUCKY.

Epidemic Diseases.—Smallpox is reported near Preston and at Wasiato; diphtheria in malignant form is prevalent in Covington and in Garrard County; and scarlet fever at Bethel, Burgin, Mount Sterling and Maysville, where the public schools have been closed.

Personal.—Dr. Charles E. Thompson has returned to Covington and resumed active practice.——Dr. H. L. Farris, Kingston, has located in Memphis, Tenn.—Dr. George W. Norman, Uniontown, has moved to Owensboro.——Dr. William R. Thompson, Mount Sterling, sustained serious injuries October 10 in a runaway accident.

Examination of Water.—Dr. J. E. Cashin, Louisville, will receive $500 for his services to the city for the examination of the water supply of the city and the water of the river at the waterworks pump to determine whether the sewage of Lakeland Asylum was contaminating it. It was decided that the sewage was a constant menace, and steps are being taken to erect a plant for the destruction of the sewage and the cleansing of the bed of the creek.

License Required in Louisville.—An ordinance has been introduced into the Louisville Common Council requiring all applicants for license to practice medicine and dentistry in the city to show a certificate from the State Board of Health and requiring a license fee of $10 to be paid in advance. The rule in the case of dentists is modified, requiring them to exhibit a diploma from a reputable college of dentistry. The city attorney explained that the object of the ordinance was to prevent unqualified men from being granted licenses.

MARYLAND.

Dr. T. W. Simmons, former health officer of Hagerstown, has brought suit against that city for $330 alleged to be due for salary.——Dr. J. C. Hummer, on the occasion of his 69th birthday, was tendered a surprise reception by Eureka Lodge, Ind. Order of Good Templars, and was presented with a handsome watch, chain and charm.

Baltimore.

A bazar for free beds in the Franklin Square Hospital of the Maryland Medical College, opened at the Hospital Building on October 14.

The deaths for the week ended October 12 were 160, being a rate of 16.6 per 1000 per annum—white 13.50, colored 30.28. Only 6 deaths were from typhoid fever.

Anti-Mosquito Ordinance Defeated.—Councilman Brown's ordinance appropriating $15,000 for the destruction of mosquitoes was defeated in the city council.

No Smallpox in Baltimore.—There are no cases of smallpox in Baltimore at this time, it being practically the only large Eastern city free of the pest. There are 5 cases in the counties.

Nurses' Home.—Work has been begun on another story and a roof garden on the Nurses' Home at the University of Maryland, owing to an increase in the number of nurses recently from 34 to 40. The work will be completed in six weeks.

Johns Hopkins Hospital Historical Club.—The first session of the Johns Hopkins Hospital Historical Club for the season was held October 14, when the following papers were read: "Jacob Bigelow," by Dr. James G. Mumford, of Boston; "William Hunter's Medical Library," by Dr. William Osler.

Opposition to Isolation Hospital.—Much opposition is manifested to the selection of the site for the Infectious Diseases Hospital in the northern part of the city near Druid Hill Park. The residents of that section are agitating the matter. The city council has threatened to withdraw the appropriation.

Northeastern Dispensary.—The new building of the Northeastern Dispensary is under way. When completed it will cost about $5000, and equipment will cost $1000 additional. Founded in 1853, this institution has occupied the same quarters ever since, although enlarged several times. The structure will be 26 by 60 feet, with brick walls, and two stories high. The first floor will contain four private consultation rooms and a large waiting apartment with seating capacity for 100 persons. On the second floor there will be two consultation rooms and another waiting room. The present staff of three resident and three consulting physicians will be increased to twelve. The institution is supported by voluntary contributions and city appropriation.

Personal.—Dr. J. Frank Crouch has returned from Europe.——Drs. William Osler and William H. Welch attended the meeting held in New York on October 12 in honor of Professor Virchow's 80th anniversary, the former being the chairman of the meeting. Both responded to toasts, the former on "Virchow as an Archeologist and Hygienist," the latter on "Virchow as a Pathologist."——Dr. Thomas S. Cullen has returned from his wedding trip.——Dr. Albertus Cotton has returned from a visit to friends in Ohio.——Dr. E. Boeninger sailed for Bremen on October 8.——Dr. David A. Medders has returned after a long visit to the Eastern Shore of Maryland.——Dr. Robert Love has returned after several months spent abroad.——Dr. Malcolm Morris, of England, lectured last week at the Johns Hopkins University, on "Medical Endowment."——Dr. Howard A. Kelly gave a reception to the Hopkins Young Men's Christian Association, at his house on Eutaw Place, October 11. The naval militia practice ship *Sylvia*, with Dr. Edward Geer in command, returned from Hampton Roads, October 7.

Johns Hopkins Report.—According to the annual report of the Johns Hopkins University just out, there were 651 students enrolled, 270 of these being from Maryland and 17 from foreign countries. There were enrolled in the medical school 209, all college graduates. Of the 143 professors and instructors, 58 are in the medical school. Last year 41 received A.B., 53 M.D. and 30 Ph.D. Since the institution began 4089 students have entered, 1617 being from Maryland. The whole number of medical degrees so far conferred is 166. A considerable part of the report is devoted to the proposed change of site. Wealthy citizens have offered 176 acres of most desirable land immediately adjoining the city on the north, provided $1,000,000 in money be raised by subscription. Efforts are to be made to secure this valuable property for a permanent location. Dr. Henry M. Hurd, superintendent of the hospital, contributes a letter describing the work of the commission of four medical men from the university who were sent to the Philippines to study tropical diseases. The Baltimore Association for the Promotion of University Education for Women has presented $800 for a fellowship in the medical school for the coming academic term, and Dr. Florence R. Sabin, a graduate of 1900, has been selected by the medical faculty as the first incumbent. Dr. Joseph R. Ames has been made director of the department of physics, made vacant by the death of Prof. Henry A. Rowland.

MICHIGAN.

"Dr." William F. Winney, Stark, was fined $10 and costs by a Northville justice, October 5, for practicing medicine without a license.

Personal.—Dr. Beverley D. Harison, Sault Ste. Marie, is visiting the Buffalo Exposition.——Dr. A. C. Wood, Glendora, has located in Coloma.——Dr. E. M. Herdman, house surgeon at the General Hospital, Sault Ste. Marie, has gone to Ann Arbor.——Dr. Arthur McGugan, formerly of the staff of the State Hospital for the Insane, Kalamazoo, has moved to Denver, Colo.——Dr. Sumner A. Edmands, Mendon, has purchased a practice in Goshen, Ind.

Mortality of Michigan.—There were 2886 deaths returned to the secretary of state for the month of September, corresponding to an annual death rate of 14.7 per 1000 population. This number is 214 more than the deaths returned for August, but is more than 400 less than the number recorded for September, 1900. There were 714 deaths of infants under one year of age; 262 deaths of children aged from 1 to 4 years, inclusive, and 697 deaths of persons aged 65 years and over. There was a marked increase in the number of deaths returned from typhoid fever and from diphtheria as compared with the preceding month.

Cornerstone Laid.—On October 15 the cornerstone of the new medical building of the University of Michigan, Ann Arbor, was laid with appropriate ceremonies. Dr. John A. McCorkle, Brooklyn, of the class of 1873, gave an address under the auspices of the Students' Medical Society; Hon. Herman Kiefer, chairman of the Committee on the Department of Medicine and Surgery, then introduced Dr. Leartus Connor, president of the Michigan State Medical Society, under the auspices of which the cornerstone was laid, who addressed the assembly. President James B. Angell and Dr. J. George Adami, Montreal, also delivered addresses, and in the evening a reception was given to the invited guests in the rooms of the Alumni Association.

NEW YORK.

The State Board of Health will give a hearing, October 15, at Yonkers, on a complaint that the Yonkers Railway Company is creating a nuisance by the use of soft coal.

Personal.—Dr. Wilhelm H. Keller, Spring Valley, has opened an office in Haverstraw.——Dr. W. F. Cregg, Norwich, has returned to Camillus.——Dr. Oliver A. Brumenthal has been appointed to examine into the physical condition of the school children of Syracuse.

New York State Medical Association.—The eighteenth annual meeting of this Association will be held at the Academy of Medicine, New York City, October 21 to 24 inclusive. In addition to a program containing many papers of merit, symposia on "Malignant Growths" and on "Arterio-Sclerosis" will be held. The annual dinner will be given in the evening of October 23, at the Murray Hill Hotel.

August Mortality.—There were 10,999 deaths in the state during August, according to the monthly bulletin of vital statistics issued by the State Board of Health. The number of deaths this month is 1300 less than July, which was excessive. The only material decrease from that month was, however, in deaths from accident and violence; there were five deaths from lightning. Typhoid fever increased from last month in all the districts, and diphtheria to a small extent; all local diseases have caused fewer deaths. Deaths from acute respiratory diseases have fallen to 500, which is low even for this month, the month of its smallest mortality; 280 of the deaths were from pneumonia. Outside of New York City there were 210 deaths from Bright's disease. Smallpox caused 40 deaths, all in the maritime district, and since August 1, cases have been reported at Scheneous and Tupper Lake, one each, two at Hillburn, three at Ellenville.

Buffalo.

Dr. Jacob Otto has been appointed assistant surgeon to the 74th Regiment, N. G., N. Y.

Dr. Ralph Harris has accepted the position as an instructor in anatomy at Cornell, Ithaca.

Dr. W. W. Carlton, Waterloo, N. Y., has received the appointment of junior house physician at the German Hospital.

Dr. Casey A. Wood, Chicago, read a paper on "Exophthalmic Goiter; Its Symptoms, Diagnosis, Pathology and Treatment," before the Ophthalmological Section of the Buffalo Academy of Medicine, October 14.

Personal.—Dr. Herman Mynter is in New York.——Dr. Herman G. Matzinger has returned to the city.——Dr. J. C. Schrader, Iowa City, Iowa, and Dr. S. W. S. Toms, Nyack, N. Y., were guests of Dr. Thomas G. Allen.——Dr. Max Einhorn, New York, was the guest of Dr. Charles G. Stockton.

New York City.

University Medical School has received a donation of $25,000 from a benefactor, who wishes his name withheld.

Inspectors of Vaccination.—The Brooklyn Board of Health has appointed nineteen physicians as inspectors of vaccination in the public schools.

Medical Institute Plans.—The following tentative working plan has been adopted by the officers of the Institute for Medical Research: To expend $20,000 a year, divided so as to provide for forty scholarships. To make appointments for one year. To have candidates recommended by heads of various laboratories to the Board of Directors. To choose only persons pursuing, or about to pursue, investigations on some important subject in pathology, bacteriology, or hygiene.

Test of Koch's Theory.—Interesting experiments of much importance are being made at the bacteriological laboratory of the Board of Health. They are being held to test Prof. Koch's theory that human tubercle bacilli will not readily infect cows or calves. So far the experiments have shown the theory to be correct, it is said. All the calves reacted to a tuberculin test, but the reaction was very slight, and may have been due to inflammation or other causes considered by the investigators at the laboratory to be of minor importance.

TENNESSEE.

A typhoid epidemic is raging at Jamestown, Fentress County, a place of about 200 inhabitants. There are now 25 cases, with 2 deaths.

Tennessee Medical College, Knoxville, held its thirteenth annual opening exercises, October 1. Dr. Charles P. McNabb, dean of the faculty, delivered the opening address.

Scarlet Fever.—Scarlet fever has been reported during the past month from seventeen counties, to the State Board of Health. Greenfield, West Point, Columbia, Gallatin, Saundersville and Shelbyville, all report cases.

Vanderbilt University Medical Department, Nashville, began its year's work, October 1, with a freshman enrolment of 75. Addresses were delivered by the chancellor of the university, and Dr. William L. Dudley, dean of the medical school.

Personal.—Dr. John Brown has been appointed assistant physician at Lyons View Asylum, Knoxville.——Dr. Douglas Haggard has returned to Nashville, after a stay of three years in New York.——Dr. W. W. Parker, Smithville, has resigned his position as pension examiner.——Dr. William W. Hill, Chattanooga, has moved to Dunlap.——Dr. Garland F. Cummins, Bellwood, is reported to be ill with smallpox.

Smallpox Statistics.—At the semi-annual meeting of the State Board of Health, the secretary reported that between April 1 and September 12, there had occurred a total of 2059 cases of smallpox in the state, with a total of 94 deaths, showing a death-rate of 4.56 per cent. Of these cases, 816 were white and 1210 colored. There were 54 cases of smallpox on hand at the time of the report, located in eleven counties. From the lay local press we learn that smallpox is present in Dalton, Bellwood, Jackson, Hollywood, Chattanooga and Rossville.

WISCONSIN.

Tear Down the Signs.—Much difficulty is being experienced in the vicinity of Kubia, where smallpox exists, by the attitude of the farmers, who object so strongly to the yellow placards that in some cases they have torn them down.

Honor Virchow.—Milwaukee physicians gave a dinner, October 12, at the Republican House, in celebration of the eightieth birthday of Professor Rudolph Virchow. A loving cup and congratulatory address, signed by those taking part, were sent to him.

The State Board of Medical Examiners held its last quarterly examinations at Oshkosh, beginning October 8, and examined twenty-two applicants for certificates to practice. The next examination will be held at the Hotel Pfister, Milwaukee, January 14.

Fire at Insane Hospital.—A fire, supposed to be originated by spontaneous combustion, started in a coal shed at the Northern Hospital for the Insane, at Oshkosh, October 5, and for a time threatened the entire institution. The roof of the morgue, a carpenter shop and 3500 tons of coal were destroyed, but no one was injured.

Scarlet Fever and Diphtheria.—There are 12 cases of scarlet fever at West Superior.——At Oshkosh there have been reported from September 1 to October 4 in all 26 cases of scarlet fever and 34 cases of diphtheria. The spread of these diseases is general in the city and the health officer fears an extensive epidemic of both diseases.

Personal.—Dr. George A. Barker, Shell Lake, will take the practice of Dr. H. M. Read, at Menomonie. Dr. Read will go abroad to study.——Dr. Horace M. Brown, Milwaukee, has returned from Europe.——Dr. E. Y. Arnold, formerly of St. Croix Falls, has located at West Duluth.——Dr. E. C. Jacobs, Durand, has associated with him in his practice Dr. A. D. Smith, formerly of Eau Claire.

Wisconsin College of Physicians and Surgeons held the opening exercises for its ninth session, September 24, Dr. Homer Sylvester delivering the address of the evening. Apparatus to the value of $1000 has been added to the laboratories. New members of the faculty have been added, as follows: Dr. McNaughton, department of surgery; Drs. Joseph Donovan and James Ryan, materia medica and therapeutics; Dr. Bjorkman, Racine, physiology, and John S. Donovan, jurisprudence.

Fumigate the Camps.—The work of fumigating the lumber camps has been begun and the places that proved last winter such excellent breeding ground for smallpox are to be thoroughly disinfected. The occupants of the camps themselves seem to realize their danger and the opposition which was manifested during the attempts on the part of the health authorities last year, is no longer present. Dr. H. J. Connor, who was appointed by the State Board of Health, has charge of the work.

Smallpox.—The alarming report that seventy-one cases of smallpox were discovered October 7, at the government school at Odanah, on the Bad River Reservation, has prompted active steps by the health authorities. The village is quarantined, the three district schools have been closed and the parochial school has been converted into a hospital. The form of the disease seems to be mild, but the sudden and widespread outbreak will make its confinement difficult.——At Stockbridge a case of smallpox was discovered in a tent-covered wagon occupied by a threshing-machine crew.——The health officer of La Crosse investigated the alleged smallpox epidemic at French Island and found the disease in three families. The places infected have been quarantined.——Three cases are reported on South Ridge, south of La Crescent, Minn.——There are now but two cases of the disease in West Superior.

CANADA.

Personal.—Dr. Albright, senior surgeon of the Elder-Dempster line, has been appointed surgeon to the Canadian Pacific Railway steamer, *Empress of India*. Dr. Fitzgerald of Montreal succeeds him.

Victoria Cottage Hospital at Regina.—Last week, while touring the Canadian Northwest with the Royal party, Lady Minto opened the Victoria Cottage Hospital, at Regina, towards the erection of which the Lady Minto Cottage Hospital Fund contributed $1,500.

From Montreal.—Montreal, too, is also threatened with another epidemic of smallpox. Only a few days ago the city was declared free from the disease, but the Provincial Board of Health of Quebec considers that owing to an outbreak at St. Henri, a suburb, and the epidemic at Ottawa, that it is important enough to issue a general call for vaccination. A special hospital is being established to deal with any cases developing.

From Ottawa.—The Capital seems to be face to face with an epidemic of smallpox. Dr. Robillard, the medical health officer, is away on his holidays and the health of the city is in charge of Dr. Law in the interim. The week ending October 6, fifteen new cases developed, and during the past week there were a good many more. The Board of Health has ordered a general vaccination, and Dr. Bryce has been summoned from Toronto to advise on the matter.

Without Tuberculin Test.—The United States Department of Agriculture has issued an order that all Canadian cattle imported into the United States for exhibition purposes during the time the International Live Stock Exposition is being held, at Chicago, may be brought in without being subjected to the tuberculin test, but they must be accompanied by a certificate from the Canadian official veterinarian stating that they are free from contagious and infectious diseases.

Notre Dame Hospital, Montreal.—The annual meeting of this hospital was held last week, and it was decided to build a new hospital in the near future. The medical report stated that during the past year 2200 cases had been treated, an increase of 177 over the previous year. The cost of each case was ninety cents per day, a decrease of eight cents, in comparison with the preceding year. Of the total number of cases treated 1854 left the hospital cured, 155 were not improved and 134 died, making the percentage 6.09. Among the total deaths 69 were in a precarious condition when they reached the hospital. In the outdoor department there were 20,078 consultations, or a decrease of 1740 on the previous year. In this department five cents is charged for consultations for those able to pay. The financial report stated that the expenses were $29,480.54, and the receipts $32,293. Dr. E. P. Lachapelle was re-elected superintendent, and Dr. Benoit, secretary. Next year the annual report will be published in English, as well as in French, owing to the increasing interest taken in the affairs of the hospital by the English-speaking population.

Ontario Board of Health.—The regular quarterly meeting was held in Toronto on October 9 and 10, the chairman, Dr. Vaux, of Hamilton, presiding. Dr. Bryce, the secretary, in his official report, stated that there had been in the province for the first nine months of the year 1064 cases of smallpox, which was the largest outbreak in Ontario in the history of the Board. Only six deaths had occurred, which was less than 1 per cent. It was estimated that over forty cases had occurred since October 1, in places including Ottawa, Oxford County, Manitoulin Island and the District of Algoma. Dr. Bryce believes that the time has arrived in the history of the Dominion of Canada when the government should establish an institute for scientific research, where vaccines and anti-toxins would be prepared. The secretary also presented another report on the question of tuberculosis, and it was recommended that municipalities be advised to stop the people from expectorating in public places, and that physicians be compelled to report all cases of tuberculosis. Further advice was given that tenements, factories, schools and other public buildings be regularly inspected to promote cleanliness, ventilation and other sanitary conditions.

FOREIGN.

Prize for Research on the Invisible Rays.—The Vienna Academy of Science will award the von Baumgartner prize of 2000 kronen at the close of 1903, for the best research work on the invisible rays.

Deaths Abroad.—Adolf Winter, professor of pharmacology at Leipsic, and formerly librarian, died September 18, in his 86th year.——The death is also announced of C. Euler, to whose efforts the Turnwesen, gymnastic athletics, owes much of its success in Germany.——G. Jablonowski, of the Berlin Anatomic Institute, 43 years of age.——H. von Wyss, professor of forensic medicine at Zurich University.——Our Grecian exchanges report the death of Jules Galvanis, professor of surgery at Athens.

Nineteen Physicians in Quarantine.—The steamer *Senegal* left Marseilles for a trip to Palestine, with 174 tourists on board, including 19 physicians and their families. Soon after leaving, a case of bubonic plague was discovered among the crew, and the steamer returned to Marseilles, where the party were quarantined. One other case occurred among the sailors, but the rest of the crew and passengers escaped. Chauffard, Richardière and Bucquoy are among the physicians who have thus been enabled to study at first hand the workings of the quarantine system.

International Congress of Physiology.—This congress convened at Turin, September 17, with about 300 members. Forster, of Cambridge, was elected perpetual honorary president, as a token of gratitude for his efforts in organizing these international congresses of physiology. Bowditch, of Boston, was elected president, and Chauveau, of Paris, second president. The members sent a telegram to Queen Margherita thanking her for the successful initiation of the laboratory of physiology, which has been constructed on top of Monte Rosa. Mosso announced that the Italian government has recently appropriated funds to equip and maintain it. He invited the nations represented at the congress to consider the laboratory an international institution and to send expeditions to it.

LONDON LETTER.

Reform in the Army Medical Corps—Drastic Charges.

At last, under the severe pressure of necessity, the War Office has been driven to grant some very substantial reforms of the Army Medical Corps. The need for such has been repeatedly pointed out in The Journal, and the fact that the so-called "hospital scandals" of the South African war were the result of the domination, and consequent muddling of army medical matters by the military authorities of the War Office. The Commission on Army Medical Department which sat under the presidency of Mr. Broderick, the Secretary for War, has been already described. Its report has just been published. The Committee recommend that the Army Medical Corps be placed under the supervision of an Advisory Board, to be composed of the following: The Director-General of the Corps, chairman; the Deputy Director-General, vice-chairman; one officer of the Corps, with special knowledge of sanitation; one officer, with special knowledge of tropical diseases; two civilian physicians and two civilian surgeons, appointed by the Crown, on the recommendation of the Secretary of State; one representative of the War Office, appointed by the Secretary of State; one representative of the India Office, appointed by the Secretary of State for India, and the Matron-in-Chief, of Queen Alexandra's Imperial Military Nursing Service—for nursing service only. To be eligible for appointment on the Advisory Board, a civilian physician or surgeon must have held a post on the staff of a leading civil hospital, and be not more than 55 years old on appointment. He shall hold office for three years, with renewal upon extirpation, but terminable upon his attaining the age of 60. He shall receive an honorarium of $1000 per annum.

But the most important reform is in the conditions of admission to promotion in the Corps. The rates of pay are considerably increased. The following are proposed: Lieutenant, $1600 per annum; captain (i. e., after three years' service), $1900; captain after seven years' total service, $2000, and after ten years, $2300; major (i. e., after twelve years' total service), $2900; major, after three years' service as such, $3150; lieutenant-colonel (i. e., after twenty years' service, $3500; lieutenant-colonel, $4000; colonel, $4800; surgeon-general, $7500; director-general, $10,000. In regard to promotion, a most important innovation is the substitution of promotion by examination for promotion by seniority. On the completion of six years' service as captain, an officer can retire with a gratuity of $5000. Should he elect to continue, between his ninth and twelfth year of service he will be attached to a hospital at one of the military centers for six months, so as to be able to study at a modern hospital; then he presents himself for examination. Having passed the examination and completed twelve years of service, he will be promoted to a majority. Three years later he can retire on a gratuity of $12,500. If he continues he will be granted three months' study leave and then be required to qualify by examination for promotion to the rank of lieutenant-colonel. This examination covers ten subjects, including the medical history of modern campaigns and the army services of other powers. If he fail to pass, he will be compulsorily retired on the gratuity last mentioned, or he may by special permission be permitted to complete twenty years' service, and retire on a pension. The committee is strongly of the opinion that the establishment of a military hospital and medical staff college for the training of officers of the Medical Corps would conduce to the efficiency of the service. Taken as a whole, the report is highly satisfactory, and its adoption must greatly improve the personnel of the Medical Corps and remove most of the crying grievances of its officers.

Sir James Paget's Memoirs.

The Memoirs and Letters of Sir James Paget, edited by his son, Mr. Stephen Paget, have just been published. The work, both from the high importance of the subject and the competence of its editor, is one of the most valuable and instructive contributions on medical biography ever published. Sir James Paget, who died nearly two years ago, was for many years regarded as the leader of the profession in England—a position which he attained by the most arduous and unremitting work, in spite of poverty in his early years. The editor of the Memoirs, Mr. Stephen Paget, is himself a surgeon and has made several valuable contributions to surgical literature. Perhaps the most important are his paper on "Inflammation of the Parotid, After Abdominal or Pelvic Lesions," and his life of John Hunter. He is master of a graceful literary style, in which the effects of heredity can be traced. The book is the story of a life full of work. The number of hours which Sir James Paget worked for many years seems almost incredible—sixteen hours a day. He was never regarded as a great operator, but as a diagnostician he was unrivaled and his opinion in a surgical case was relied upon as the highest that could be obtained. The universal feeling of respect with which he was regarded, both by the profession and society generally, was inspired not only by his professional skill, but also by his character as a man, absolutely above the suspicion of ever being actuated by any but the highest motives. His son says of him: "He was very proud of his profession, and proud of his own hard work for it and in it; he never dreamed of being above it, or of going outside the limits of it; and its service was perfect freedom to him."

Smallpox Outbreak.

There are now 160 cases of smallpox in hospitals in London, and 5 new cases were admitted on the last day of the report. Though the number can not be described as alarming a disquieting fact is that cases occur in all parts of the vast metropolis. The local government board has issued circulars to the borough councils and boards of guardians of the poor instructing them to take energetic measures in connection with the cases—to isolate the patients, vaccinate persons exposed to infection and disinfect the premises. The neglect of vaccination, which is partly the result of the recent act abolishing compulsion in response to the clamor of anti-vaccinators, is to some extent responsible for the outbreak. Thus in the Borough of Hackney it is estimated that in a population of 50,000 children under the age of 10, 20,000 are unvaccinated. Here the authorities are exerting themselves to the utmost to prevent the disease obtaining a hold on the parish. The residents of several of the infected houses are being paid $5 a week on condition that they do not leave the building or send their children to school. The total deaths from smallpox, which had been 7, 7 and 9 in the preceding weeks, fell last week to 3.

A nurse in a Paris hospital fatally burned a child by placing it in almost boiling water. She was condemned to 15 days' imprisonment and 2000 francs damages.

THE VIRCHOW ANNIVERSARY IN NEW YORK CITY.

The medical world did honor to Dr. Rudolph Virchow, last week, on the anniversary of this great man's eightieth birthday, by a dinner which was held in New York, at Sherry's last Saturday, to which over 100 representative medical men sat down.

Dr. C. L. Dana had devised an ingenious and handsome menu. It represented a facsimile of Virchow's *Archiv für Pathologische Anatomie*, with its familiar green cover; within there were two portraits of Virchow. One was taken at the age of 38, and had been given to Dr. Andrew H. Smith, of New York, who in 1858-1859 was a student in Berlin. A later portrait of Virchow, at the age of 78, was also included in the menu. Following this was a list of the more important publications of Virchow on matters medical, anthropological, hygienic and social.

Following the dinner, Dr. William Osler, acting as chairman, spoke of Virchow as a scientist, more particularly as an anthropologist and hygienist. He said that they had gathered, this night, for a notable occasion and on a notable night, for, eighty years ago, there had been born into the world of medical science, a genius. Genius, he said, had been defined as a matter of birth and environment. With reference to this last factor, Virchow had been fortunate, since he had had the privilege of being a student under Johannes Müller. What this had meant to the young man was well expressed in Virchow's address, given at the death of his master. At the time of Müller's entrance into the medical arena, vague and mystical conceptions of disease were taught, but he had introduced into the science of pathology the too long forgotten ideas of the old Greek philosophers and teachers. Observation, study and analysis were the fundamental considerations of these early physicians, and it was to the undying credit of Johannes Müller that the processes of exact observation were brought to bear on the problems of disease.

Speaking of his work in the field of archeology, Dr. Osler said that it was not a mere dilettante, but as an ardent and faithful student; that he was not a mere dabbler in skulls and in relics, but a recognized master; and no congress of archeology was ever complete without his presence.

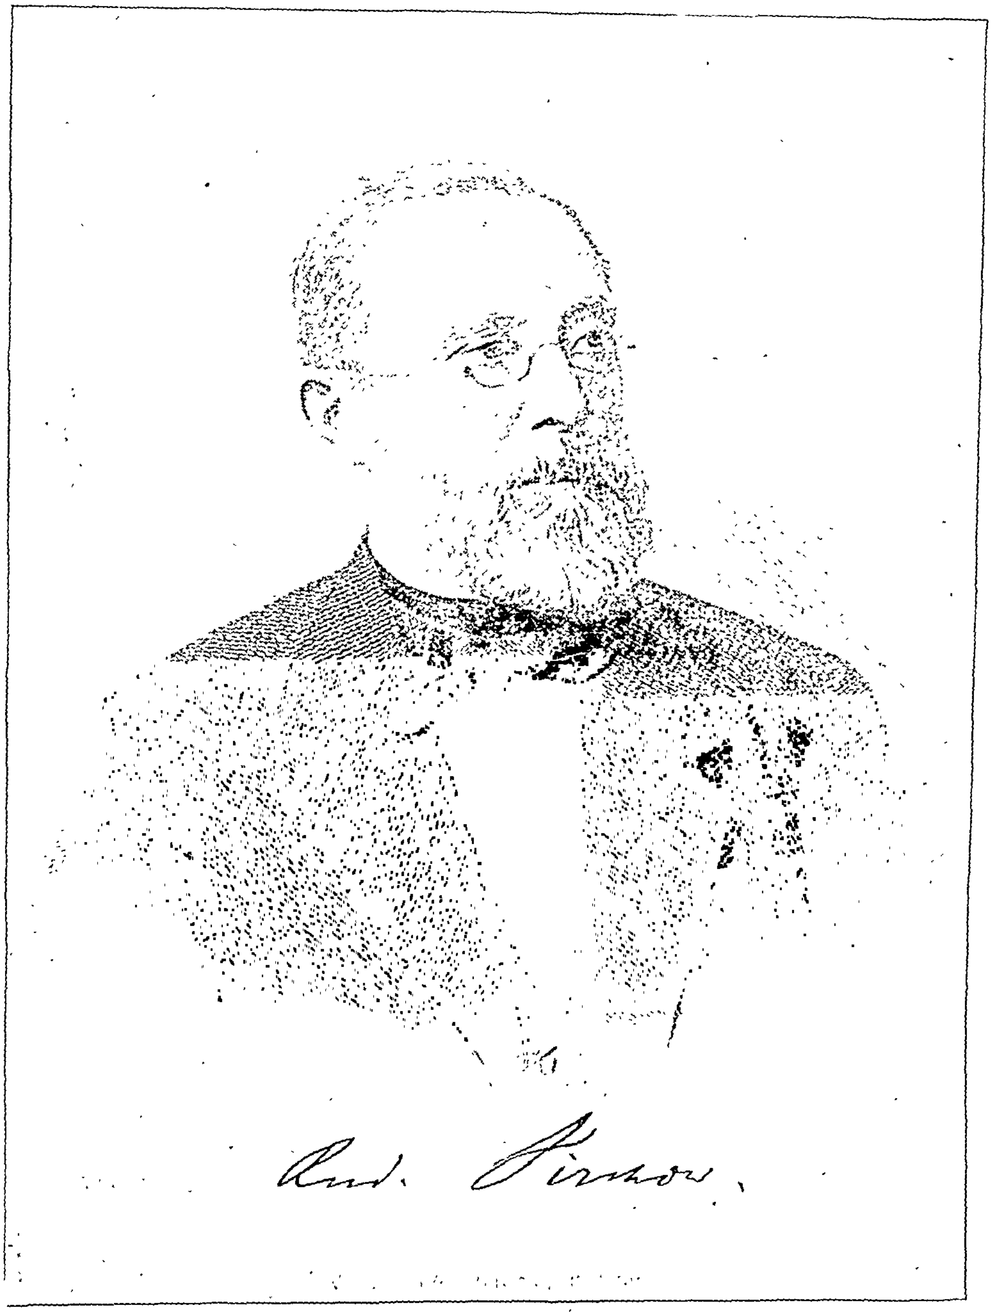
With Pettenkofer, of Munich, he shared the honor of being the foremost authority of Europe in matters connected with public hygiene, and the Prussian Government, and more particularly the city of Berlin, owed much to his genius as a hygienist. The list of his contributions to preventive medicine, as revealed in his "Gesammelte Abhandlungen," bears testimony to his extraordinary fertility of idea and activity in execution.

Dr. Gould, of Philadelphia, then read a telegram of congratulation to Dr. Virchow from his friends and admirers in America.

Dr. W. H. Welch, of Baltimore, spoke of Virchow as a pathologist. It would take, he said, a genius approaching Virchow himself, in attempting to correctly present this many-sided man. As an anthropologist, he was an acknowledged authority, and Dr. Welch related an anecdote, in which an acknowledged authority in anthropology had asked Dr. Welch if Virchow had any reputation in medicine, as he had always thought of him only as a fellow anthropologist.

Virchow, he said, had been an integral part in the great renaissance that had been going on in science, in whose collateral branches such men as Brucke, Myers, DuBois, Raymond, Helmholtz, Schroeder, and others were such notable lights. He had been fortunate in the choice of his early studies, for in the observations that he made on the chemistry and the morphology of the blood; in his later studies on inflammation, and in his work on cellular tissues, he was working with the fundamental problems of pathology. His work on thrombi and emboli constituted an epoch in the study of disease processes, and his "Cellular Pathology," which appeared in 1858, was a classical work, making a step forward for all time. It is true that its foundations have been attacked, but they have never been superseded. Certain details have been modified, but the fundamental truths are truths for all time. Morgagni had first brought into prominence the importance of *organs*, Bichat had shown the relations of the *tissues*, but Virchow laid the foundations of pathology in the study of the cell. One of the most important precepts to be learned from Virchow's work is the value of method as opposed to doctrine. Disease, for him, was "life under changed conditions," and it is this attitude towards the investigation of vital problems that has placed pathology so high in the sciences.

Dr. Andrew H. Smith, of New York, spoke of Virchow as a teacher and as a man, and gave a number of pleasant reminiscences of his student days of 1858-1859 in Berlin. One of the things that most strikingly appealed to his mind was the method that Virchow had inaugurated in the dead-room. Traube was then active in his teachings and many of his postmortems were associated with the smell of burnt meat, as he used small red-hot irons. The postmortems were then conducted with the view of ascertaining what the patient died of and the affected organ only was examined with any minuteness. Dr. Smith said that he had been electrified to see Virchow open the body from the chin to the pubes with one sweep of his butcher's knife and he would then make the dead man tell his secrets, so searching was the scrutiny. The new point of view of learning everything possible from the dead body was a revelation.



Rud. Virchow.

Dr. Smith also spoke of Virchow's early resolve to write in a simple and straightforward style and his written and spoken words were always expressed with a clean-cut straightforwardness, rarely found in medical literature. As a man, Virchow was very democratic and approachable. He was always pleasant and ready to aid his students and above all was a constant stimulus to accurate observation.

Dr. Jacobi then spoke of Dr. Virchow as a citizen. He dwelt particularly on Virchow's public work, from the time when he first lost governmental favor by his honest and enlightened report on the typhus epidemic in Silesia in his early manhood to his latest parliamentary services. Reform in society as well as in science has been his forte; the city of Berlin, with its model administration, owes largely to him the fact that it is a cleanly, healthy, well-governed city, in spite of constant interference. The empire is indebted to him for the organization of the medical care of its soldiers in its later wars, and in this connection Dr. Jacobi quoted Virchow's appreciative acknowledgment of our own country's contributions to the medical science of war. For nearly fifty years Virchow held a seat in the town council of Berlin, for dozens of years in the representative council of Prussia and the imperial parliament; he has always stood firm for principle and right. While engaged in scientific research, which in universality and importance has been rarely even approached by others, he has never forgotten that his services also belonged to his countrymen; his example should teach young medical men that the pursuit of science and good citizenship are not mutually exclusive. His life is a great lesson that we should learn, no matter how high our scientific position or vast our learning we belong to our fellow-men in duties of reciprocity and good citizenship. But we may never have an opportunity again to thus honor one who has been equally great, alike in science and citizenship. One thing we may say of him, with Goethe: "He has satisfied the best of his era, he has lived for all time."

Miscellany.

Malaria Simulating Hydrophobia.—At the recent Pan-Hellenic Medical Congress, held at Athens, Nicolettis reported a case of apparent acute hydrophobia in a child, who exhibited *all* the ordinary symptoms, including biting the persons around. He was not known to have been bitten by any animal, but had a history of preceding malaria. Nicolettis diagnosed the case as pernicious malaria, instead of hydrophobia, and injected quinin subcutaneously, with complete cure of all the symptoms in three days. In the treatment of malaria, one member of the congress lauded a mixture of quinin and methylene blue as very effective in his experience, while another ascribed great therapeutic efficacy to a combination of belladonna, quinin and iodoform.

An Accouchement in Dahomey.—Dr. Blin describes, in the French *Annales d'Hyg., etc. Coloniales*, 1901, 1, the peculiar features of an accouchement of a Dahomey high caste woman at which he was allowed to be a spectator. During the last stage, two women massaged the thighs and flanks of the patient continuously, scolding her at any expression of pain. A stopper of herbs rolled into a wad, was inserted in the anus—"a hygienic measure highly to be recommended," he remarks, "for the sake of both the infant, the mother and the accoucheur." A round piece of wood like a broom handle anointed with palm oil and aromatic substances, was introduced into the patient's mouth and pushed down into her throat. The purpose of this was to retain the air in the thorax as one instinctively closes the glottis in straining during defecation. Boiling water was used copiously in cleansing.

Simple Test for Fat in the Blood.—Zaudy, of Ebstein's Clinic, describes in the *Deutsche Archiv f. Klin. Med.* for June, a very simple method of detecting lipemia. A small drop of blood is drawn on the center of a cover glass which is inverted and the hanging drop examined. The serum that collects in a drop of normal blood is perfectly clear, but in case of lipemia it is turbid, of a bluish or grayish white or even milky hue, if examined within the first few hours. The microscope shows the droplets of fat, but the macroscopic aspect of the serum is sufficient to disclose the lipemia. The only source of error is that an excess of fibrin may simulate the fat, but the microscope reveals the difference at a glance. The blood from a large number of patients was examined, all suffering from affections usually considered as associated with lipemia, but no fat was found in the blood except in the diabetic patients. It is possible to trace the course of a fibrinous pneumonia with this hanging-drop method. The blood from lying-in patients always showed a ring of fibrin around the clot.

Treatment of Obesity.—E. Stadelmann describes, in the *Berliner Klin. Wochenschrift* for June 24, a case of obesity in which the weight was reduced 120 pounds in a year. This was accomplished by restricting the diet to the amount of calories which experience showed was just below the amount on which the patient increased in weight. She gained on 1200 and lost on 1000, consequently the diet was restricted to an average of 125 gm. of albumin, representing 514 calories; 32 gm. fat, or 300 calories, and 49 gm. carbohydrates, or 200 calories, a total of 1014 calories a day. No restriction was imposed on the amount of water and green vegetables were allowed in abundance. The ration for one day, for example, was 400 gm. coffee, without milk or sugar, 80 gm. graham bread, 200 gm. roast pork, 80 gm. boiled ham, 500 gm. tea, without milk or sugar, 80 gm. Schweizerkäse and 400 gm. cucumber salad. Stadelmann believes that thyroid treatment of obesity is dangerous and superfluous, as equally good if not superior results can be attained by underfeeding, adapting the number of calories to the individual case, and varying the proportions of fats and carbohydrates from time to time to make the diet more acceptable to the patient. Even at the best, the treatment of obesity is a severe strain on the patience and will-power, and the physician's strict and constant oversight is needed.

Arrhythmia in Fatty Degeneration.—Kisch states that the probable reason why intense arrhythmia is noted in one case of fatty degeneration of the heart, while the heart action is still regular in other cases in which the degeneration of the myocardium is equally pronounced, is that in the former case, the nervous apparatus of the heart is affected, directly or indirectly, by the morbid process. This extreme, persisting arrhythmia is always an ominous sign, he says, indicating heart failure liable to occur at any moment in consequence, possibly, of some very slight oxerexertion or increased resistance in the vessels. It may be the first indication of latent fatty degeneration of the heart in persons inclined to fat, and should rouse the physician to energetic measures directed to the relief of the task imposed on the heart, and to aid the recuperation of the degenerated myocardium. Kisch is physician at Marienbad and he states that he has been able to prolong life and relieve the patients in many apparently doomed cases. He illustrates typical tracings, in such cases, in the *Wien. Med. Woch.*, of May 25. They are distinguished by the alternation of a number of regular pulse waves with a few small, rudimentary waves, and, possibly, occasional pauses. Or the regular waves may occur irregularly between abnormally large, protracted waves and the rudimentary. The pulse may be retarded or accelerated.

Correspondence.

American Humane Association.

Toledo, Ohio, Oct. 3, 1901.

To the Editor:—My attention has just been called to your long editorial in The Journal of September 14, wherein, among other things, you question the accuracy of my statements. Your sense of fairness, I doubt not, will permit me to make, through your columns, a brief reply.

Referring to the pamphlet "Concerning Human Vivisection" issued by The American Humane Association, you say:

"If the Association had really desired to put the matter fairly before the public, why did it not include Dr. Keen's last letter? If it had done this, the anonymous reviewer would have had an opportunity to point out the 'serious misquotations' spoken of by Mr. Brown in his recent communication, if they existed, a possibility of which we have our doubts. A writer who . . . leaves an important term like '*carcinoma dissemine*' in the original rather than put it into intelligible English is not one that inspires faith in his criticisms or the accuracy of his assertions."

1. The answer to your first question is easy enough. The pamphlet "Concerning Human Vivisection" was published at least three weeks before Dr. Keen's "last letter" appeared in your columns; its introduction is distinctly dated July 1, 1901. How could Dr. Keen's letter of August 10 appear in a pamphlet printed and in circulation in the preceding month?

2. The important term "carcinoma dissemine" does not appear in the *Review*, except as embodied in a long letter from the special correspondent of *The British Medical Journal*. Doubtless he will appreciate your criticism; but I fail to see why his language should have been changed, or why his fail-

ure to translate a perfectly intelligible phrase should inspire doubt as to the accuracy of his assertions.

3. You doubt the possibility of my pointing out in Dr. Keen's letter any serious misquotations. Will The Journal grant me the space to prove it? If so, the proof of his garbled quotations shall be furnished. But in his interest, I protest against being called upon to furnish them in your columns.

4. Speaking of Animal Vivisection, you say that "the courageous application of the facts thus gained on human subjects falls fairly within what Mr. Brown . . . would call "human vivisection." Not at all! Evidently, you are entirely ignorant of what The American Humane Association means by the term. It was thus defined on the first page of the original pamphlet: "The phrase 'Human Vivisection' must not be taken as having any reference to the experimental use by physicians of new methods or new remedies, with a view to the benefit of the patient. To such tests, in the vast majority of instances, there can be no objection. But 'human vivisection' is something entirely different. It has been defined as 'the practice of subjecting human beings, men, women, and children, who are patients in hospitals or asylums, to experiments involving pain, mutilation, disease or death, for no object connected with their individual benefit, but entirely for scientific purposes."

5. You state regarding unjustifiable experiments on human subjects, that there have occurred "a few rare instances of the kind, that were promptly condemned by the profession generally, long before The Humane Association ever paid any attention to the subject." I am very glad to know this upon your authority. If now, you will kindly quote from your own periodical, a single case in which an experimenter of this kind has been, by name, condemned or censured in your editorial columns since The Journal came into existence, I shall be glad to give your words that wide publicity which they deserve, as illustrating the attitude of the medical profession towards this atrocious practice. Yours very truly,

James M. Brown,
President American Humane Association.

Ans.—The Journal received the pamphlet in question about five weeks after the publication of Dr. Keen's last letter. We have not been accustomed to consider the date on the introduction as the date of printing of a work, and, supposing we had been promptly furnished with a copy, it was not unjustifiably assumed that its producers had had time to see The Journal of August 10 and include the latest statement of Dr. Keen. Anyone can put any date he pleases on the preface to a pamphlet; it is no evidence of the time of a book's appearance. We repeat that it would have been better for their pretense of fairness if The Humane Association had held back their pamphlet, if necessary, a few days to present also this last letter.

As regards the retaining the term "carcinoma dissemine" instead of putting it into English, it might do in a medical journal, though it looks pedantic, but, whether in a quotation or not, it ought not to be left without explanation in a pamphlet addressed to the laity. It disguises, so to speak, the facts in the case, that the patient suffered from generalized cancerous infection. While not approving of the procedure we can not say that auto-inoculation in such a case had any more effect on the feelings of the patient or the prognosis of the case than there would be in general leprosy, or from the addition of another pustule in a case of discrete variola. That, however, is evidently not the impression intended to be conveyed by The Humane Association's writer and he refrains from any explanation of the term, though, if he is at all familiar with medical terms, he must have been aware of the very possible trifling nature of the operation. The term as used by him can not be said to be "perfectly intelligible" to the average reader.

Dr. Keen, who is now in Europe, is perfectly able to take care of himself and one may reasonably doubt Mr. Brown's word that he has made any serious misquotations or that Mr. Brown is likely to want to spare him any exposure of them if he can do it. We may also be reasonably excused from giving any space to those who garble extracts and excuse deliberate misrepresentations under the plea of "free translation." As regards our alleged misapprehension and ignorance of what is meant by human vivisection, we shall hold our position. In fact, according to the definition given, hardly one of the cases of alleged human vivisection cited could be said to have been done entirely for scientific purposes; there was a therepeutic end in view in nearly every one, if not all. This does not, of course, justify the infliction of needless suffering, or criminal recklessness.

The Journal has editorially condemned human experimentation in the past as it does at the present, but it can not approve of exaggeration and misrepresentations or the attempted inference that it is not condemned by the medical profession. That this is not the case is shown by the fact that The Humane Association's anonymous writer has to quote such condemnation, though he apparently tried to avoid it, as in the case noted by Dr. Keen. The impression conveyed to disinterested laymen by his article is shown by an editorial in the *New York Evening Post* which sees in it "not an answer to Dr. Keen's specifications, but an attempt to hold him responsible for things he has not said or done. It puts him in the attitude of exonerating physicians who have been charged with experiments producing unnecessary pain upon poor and helpless patients in hospitals. No impartial reader will derive such an impression from anything he has said." We do not see the utility of further lending our columns to those whose main object appears to be the libeling of the medical profession, through garbled quotations and direct misrepresentation by an anonymous writer.

The Banquet to Dr. N. S. Davis.

Hartford, Conn., Oct. 12, 1901.

To the Editor:—The testimonial banquet to Dr. Davis, so warm and appreciative in its recognition of his great service to medicine, and to medical men, failed to note the real monument which he has been building for the future.

The recent great advances of science have pointed out the wisdom and prescience of the persistent and insistent efforts of Dr. Davis to make known the dangers from the use of alcohol. For nearly half a century from laboratory and clinical experience he has called attention to the errors and delusions which have invested the alcoholic problem.

Dr. Rush, the great physician of the last century, is more often quoted to-day and is more vividly remembered for his statements of the nature of alcohol and the diseases which follow than for any other work he did.

Condelac, a noted French philosopher of the eighteenth century, is unknown to-day; his name is rarely mentioned except as having urged that inebriety was a disease and curable.

History has many similar examples of prominent men in their day whose memory was only known to the future by what they said regarding some unpopular subject, which later was recognized as a great truth. It is this work of the recognition and defense of great facts which are denied at the time, that make such men the pioneers. These men open up new territory and mark out paths for larger truths in the future. There can be no doubt that the great impending alcoholic problems of this new century will refer back to the efforts of a few men of which Dr. Davis is the great leader, and who, like scouts, far in advance of the army of scientific progress, indicate the direction and line of march.

A host of friends all over the country extend to Dr. Davis their heartiest greetings and confident assurance that his name and reputation is not limited to this day and generation.

T. D. Crothers, M.D.

Laxity in Pension Examiners.

Bloomsburg, Pa., Oct. 10, 1901.

To the Editor:—In an article in The Journal of October 5 on "Laxity in Pension Examiners," the claim is made of "certain abuses" of "serious carelessness," and that the public has "a conviction of a vast amount of fraud in the pension business," and that the publication of such facts as these confirm it. Let us examine the alleged facts. If they are true, then the above allegations stand. If they are false, then they fall. The "facts" consist of an experience with one board of pension examiners, who examined twenty applicants at once, from one section and found them all suffering from heart disease. These applicants were then examined before disinterested physicians who found no heart disease in any of the cases. Is this probable? Is it possible, that twenty soldiers aged from 55 to 75 years, who have suffered all the privations of army life, and subsequently the most of them the hardships of severe manual labor in attempting to maintain their loved ones, that not *one* had heart disease? I doubt if it is possible to take twenty men with *no* army experience between the ages of 55 and 75 years and not find one with heart trouble.

The sentiments of your article are so similar to others recently published, as to excite the suspicion of a common inspiration. Many of your subscribers are pension examiners. Were you to obtain their experience as to the prevalence of heart disease among pensioners it would go far towards establishing the question as to who is right in the controversy between the Commissioner of Pensions and the Grand Army.

J. J. Brown, M.D.

A Medical Weekly Criticised.

Pawtucket, R. I., Oct. 2, 1901.

To the Editor:—I am glad you noticed the editorial of a certain medical journal reflecting upon the physicians who attended our late lamented President.

It is a deplorable state of affairs when a journal that should be cautious and dignified, rushes into print editorially with a hysterical attack upon the good name of our profession backed by nothing but hearsay. The proceeding was a disgrace to journalism and if I were a subscriber of this weekly I should consider it a duty to myself and my profession to refuse to accept it in the future.

According to certain "yellow newspapers" this medical publication is the "mouthpiece of the profession." Where those poor deluded scribes got the information I can not imagine, but sufficient to say they never heard of the American Medical Association or The Journal, or of a number of other favorably known medical journals, for if they had, reckless as these men are, I believe they would hesitate before writing such a glaring misstatement.

I believe that a medical journal that assumes such an attitude toward the profession is unworthy of support. The editorial not only reflected upon the gentlemen immediately concerned in this case, but upon the whole profession, and while this editorial was inconsistent and absurd to the professional mind, it certainly made the profession ridiculous to the lay mind.

Yours very truly,
Francis M. Harrington.

The Septic Tank.

Chicago, Oct. 9, 1901.

To the Editor:—In The Journal of September 28, the City Clerk of Vancouver, B. C., states in a very positive way that the City of Vancouver was the first to introduce the Septic Tank System into the Dominion. This is an error. The first septic tank system to be introduced in the Dominion of Canada was installed at the Mount Allison University, Sackville, N. B., and was put into practical operation in October, 1900.

I should perhaps explain that, as general agent for the septic tank syndicate at Exeter, England, I secured the introduction of this system, both at Vancouver and Sackville, and on March 12, 1901, I received a letter from Dr. Allison, President of the University, reporting the very satisfactory working of our system. In the interest of your readers, perhaps you would like to get a later report from the Doctor, which I think he would be very glad to give you, but in justice to Dr. Allison I think Dr. McGuigan's statement should be corrected.

Yours very truly, H. D. Wyllie,
General Manager Cameron Septic Tank Co.

A Warning.

Philadelphia, Oct. 12, 1901.

To the Editor:—I desire to warn the profession against the operations of the Merchants' and Physicians' Adjusting Agency, of 346 Broadway, N. Y. Their scheme is to agree by written contract to collect bills for two years for $25, half of the first $50 collected. The doctor must bind himself to send every 20 days for five times, twice as many stamps as the number of debtors to whom letters will be sent. The point here is that if the physician should forget to send the stamps within the time mentioned, such is the wording of the contract, that he must forfeit $25 and risk hearing nothing more about his accounts. Should he refuse to pay, they threaten and demand a promissory note as the only concession. The nefarious trick is quite obvious.

H. S. Anders, M.D.

Gangrene Complicating Pregnancies.

Austin, Texas, Oct. 11, 1901.

To the Editor:—For the benefit of the statistic-pathologist, allow me to report that several years ago, a primipara, of this city, lost one of her feet, and part of the ankle, as a result of gangrene, complicating parturition. The patient fully recovered, and has since borne five healthy children, all of whom are now strong and well. Personal observations lead us to believe that such complications are not so rare, or so fatal, as many writers would have us to believe.

Q. C. Smith, M.D.

New Instrument.

A SIMPLE MECHANICAL DEVICE TO PREVENT THE MISCOUNT OF SPONGES.

Miss Zell Converse, Graduate Nurse.
COLUMBUS, OHIO.

The unfortunate accident in a Columbus hospital a few years ago, and the universal expression of trained nurses as to the responsibility assumed by them in accounting for the sponges used, impresses upon the mind of the writer not only the convenience and value, but the almost absolute necessity of some arrangement which would render a miscount impossible.

The following described simple device then came to mind, and was suggested to one of our leading surgeons, who has since used it both in hospital and private practice; in a published report he speaks of it as devoid of complications and in every way eminently satisfactory. Any ordinary table may be used, but one at least 36 inches in length and a little wider than is necessary to hold two sponge basins, will be found most convenient. To this is attached at the back of the top an upwardly inclined surface about 36x36 inches with three hooks, one at each upper corner and one in the center from which the unfolded package of sponges is suspended.

The sponges are made of surgeon's gauze in two sizes; one size 9x9 inches, and the other, 12x12 inches. Each package is made up of a piece of muslin or cotton flannel, measuring 30x36 inches and divided by colored threads into squares, three of which are 12x12 inches, and the eight remaining, 9x9 inches. Colored thread run in by machine easily marks the squares. Three loops of tape, one at each upper corner and one in the center of the muslin, are for suspending from the hooks on the table. To each square a sponge is lightly caught by a very fine thread at each upper corner—indicated by dots in the diagram. The muslin is then folded upon itself, rolled up and sterilized. At the beginning of the operation the sterilized package is unrolled and suspended by the loops of tape from the hooks upon the inclined surface at the back of the table, where the nurse and everyone present can, at a glance, see that each square is occupied by a sponge. If the unbleached muslin is used the difference in color in the muslin and the sponge would make the absence of a sponge the more quickly detected. The sponges being so lightly attached are then easily removed to the basins. When the time comes for counting, the nurse quickly wrings out and places each sponge in its space on the muslin. This takes no longer than to count them over and if each space is occupied, as in the beginning, the surgeon, nurse, and others present see that there can be no mistake and there need be no further anxiety.

The inclination of the surface and the sponges now being wet makes them adhere without other attachment. No loose sponges should be allowed in the operating room, and ordinarily, not more than one package will be needed if the sponges are washed and returned as needed to the surgeon by the nurse. A number of these packages, however, should be on hand, and for those cases in which it is not best to return the sponges, as many can be used as necessary by simply hanging a second and third package over the first. In such cases, it is best when counting, to fill the spaces on the last or top piece of muslin, roll them up and remove them from the table, then fill the next and so on. In regard to asepsis there need be no fear of using a sponge after accounting for it, as placing them on the already sterilized muslin keeps them still surgically clean.

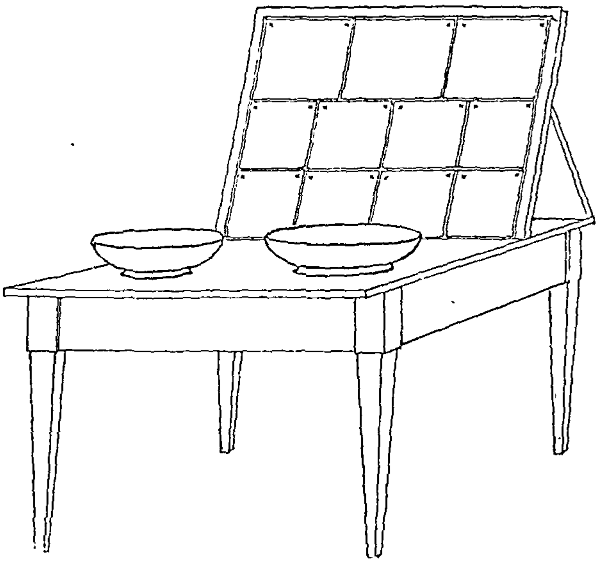


Table with sponges and basins ready to begin operation.

441 East Town Street.

Married.

Jacob F. Brenckle, M.D., Kulm, N. Dak., to Miss A. Boll, at Milwaukee, Wis.

John M. Conley, M.D., to Miss Beatrice M. Roche, both of Oshkosh, Wis., October 1.

Daniel S. Heyn, M.D., to Miss Stella Obendorfer, both of Cincinnati, Ohio, October 7.

William D. Sumpter, M.D., to Miss Tommie Wrenne, both of Nashville, Tenn., October 10.

James Edward Poore, M.D., to Miss Lady Pearl Payseur, both of Lancaster, S. C., October 10.

Claudius W. West, M.D., White Rock, Nev., to Miss Ethel M. Egan, Galesburg, Ill., October 7.

Joseph W. Anderson, M.D., Pittsburg, Pa., to Elizabeth S. Jarrett, M.D., Norristown, Pa., October 3.

Charles H. Clark, M.D., Washington, D.C., to Miss Cora Esther Taggart, Massillon, Ohio, October 17.

Gustave A. Petersdorf, M.D., Indianapolis, Ind., to Miss Golda F. Hunter, Memphis, Tenn., October 3.

Louis Albert Aldridge, M.D., to Miss Amelia Catherine Engel at New Windsor, Carroll Co., Md., September 26.

Deaths and Obituaries.

Richard S. Griswold, M.D., Bellevue Hospital Medical College, New York, major and surgeon, U. S. Volunteers, assigned to the Ninth U. S. infantry, was killed at Samar, Philippine Islands, while on duty with a company of that regiment, aged 31. Dr. Griswold, after his graduation served as assistant to the late Dr. Melancthon Storrs, Hartford. He served as assistant surgeon of the First Connecticut Infantry, U. S. V., during the Spanish-American war, and soon after its close, he passed the examination and was appointed assistant surgeon of Volunteers with the rank of first lieutenant, being assigned to the Twenty-sixth Infantry, U. S. V. While on sick leave he went from Manila to China and was present at the capture of Tien Tsin with the Ninth U. S. Infantry, and was commended in dispatches. In June, 1891, he was appointed major and surgeon of Volunteers, returned to Manila and served with the Ninth U. S. Infantry until his death. He was a member of the Hartford Medical Society.

Frederic C. Winslow, M.D., Northwestern University Medical School, 1874, died suddenly in Chicago, October 10. After his graduation he practiced in Jacksonville, Ill., and was for eighteen years assistant superintendent of the Central Hospital for the Insane at that place. After leaving that position he conducted a private sanatorium until appointed by Governor Tanner superintendent of the State Hospital. Governor Yates recently appointed him superintendent of the Hospital for the Incurable Insane, Bartonville, near Peoria. He was a member of the American Medical Association.

John R. Everhart, M.D., University of Pennsylvania, Philadelphia, 1853, died at his residence in West Chester, Pa., October 8, aged 74. After graduation he studied in Paris, and at the outbreak of the Civil war became surgeon of the Ninety-seventh Pennsylvania Infantry. To his vigorous treatment and extreme care in the enforcement of sanitary regulations was due the control and final conquest of yellow fever among the troops stationed, in 1862, at Hilton Head, S. C. After the close of the war he traveled extensively and wrote several books on travels.

Rezin P. Johnson, M.D., an old resident and practitioner of Canton, Ohio, died in Chicago, where he had resided since his retirement from practice in 1890, October 9, from typhoid fever, aged 62. He was graduated in 1861, and at once entered the United States service, serving throughout the war as assistant surgeon of the One Hundred and Fourth Ohio Volunteer Infantry.

Frank H. Cilley, M.D., University of Vermont, Burlington, 1874, who practiced in Barnet, Vt., for seven years and in Jericho for thirteen years, died, October 3, at the Mary Fletcher Hospital, Burlington, after an illness dating back to an injury received in a railway accident eight years previously, aged 54.

Alexander G. McRae, M.D., Bellevue Hospital Medical College, New York, 1891, was found dead in the basement of his home in Calumet, Mich., October 9. His death was caused by an electric shock. He was 36 years of age, and was resident physician for the Osceola Mining Company.

John S. Bloomington, M.D., Rush Medical College, Chicago, 1870, who practiced medicine for a time and then became interested in life insurance, and founded and edited the *Investigator* in 1874, died at his home in the Hotel Del Prado, Chicago, October 3, from pneumonia, aged 58.

O. Cyrus Kendrick, M.D., Jefferson Medical College, Philadelphia, 1848, formerly in charge of the State Hospital for the Insane, Newburgh, N. Y., and for several years a practitioner in East Cleveland, Ohio, died at his residence in East Cleveland, October 8, aged 79.

Ernest H. Hoffmann, M.D., Washington University, St. Louis, 1861, a pioneer practitioner of Omaha, who served throughout the Civil war as surgeon at Jefferson Barracks, Mo., died from angina pectoris at his home in Omaha, October 8, aged 65.

Ruffin B. Ellis, M.D., University of Pennsylvania, Philadelphia, 1866, one of the oldest and most esteemed practitioners of Raleigh, N. C., died at his home in that place from the effects of a paralytic stroke, October 2, aged 68.

Thomas J. Babb, M.D., Medical College of the State of South Carolina, Charleston, 1848, died at his home, Cherry Creek, Miss., October 8. He had practiced medicine in Pontotuc County for more than half a century.

Henry K. Hershiser, M.D., Columbus (Ohio) Medical College, 1881, one of the oldest practitioners in Seneca County, Ohio, died at his home in Tiffin, October 8, from paralysis, after an illness of two weeks, aged 71.

M. Garst, M.D., Jefferson Medical College, Philadelphia, 1837, formerly a practitioner in Dayton, O., and Champaign, Ill., died at his home in Coon Rapids, Iowa, October 5, after a short illness, aged 86.

Joseph E. Barrett, M.D., University of Michigan, 1861, a prominent physician of Wooster, Ohio, and surgeon of the Twenty-third Ohio Infantry in the Civil war, died at his home, October 3, aged 68.

George C. Mathews, M.R.C.S., Ireland, and M.R.C.P., Edinburgh, Scotland, 1871, a prominent physician of Jacksonville, Fla., died at his home in that city, October 1, after an illness of five days, aged 52.

Richard H. Burke, M.D., Rush Medical College, Chicago, 1883, formerly a resident of Watertown, Wis., but of late years a practitioner of San Jose, Cal., died at Los Angeles, Cal., October 4, aged 45.

E. H. Edwards, M.D., Medical College of the State of South Carolina, Charleston, 1856, died at his home in Due West, S. C., October 1, after an illness of two months, from blood poisoning.

Charles W. Petty, M.D., University of Vermont, Burlington, 1871, of Keeler's Bay, Vt., died suddenly from heart disease while making a professional call at Grand Isle, October 5, aged 53.

Everett B. McKinley, M.D., Starling Medical College, Columbus, Ohio, 1883, died from the effects of carbolic acid, taken in error, October 7, at his home in Vaughnsville, Ohio, aged 55.

John F. Gudgel, M.D., Kentucky School of Medicine, Louisville, 1879, died at his home in Hazleton, Ind., where he had lived for 27 years, October 5, after a long illness, aged 51.

Alfred R. Allen, M.D., University of Vermont, Burlington, 1882, was found unconscious near his home in Parishville, N. Y., October 7, and died without regaining consciousness.

Henry Simmons White, M.D., College of Physicians and Surgeons, N. Y., 1866, once an assistant surgeon, U. S. A., died at his home in Red Bank, N. J., September 29, aged 56.

Torrey T. Prestigar, M.D., Keokuk (Iowa) Medical College, 1894, St. Louis College of Physicians and Surgeons, 1895, died at his home in Sioux City, Iowa, October 5.

Alfred C. Lemberger, M.D., Louisville Medical College, 1893, died suddenly in his office in Louisville, on the morning of October 5, from heart disease, aged 34.

William Ullrich, M.D., a retired practitioner, who had been in feeble health for several years, died at his home in Waukesha, Wis., September 26, aged 83.

George W. Christian, M.D., University of Alabama, Mobile, 1873, died in his office in Austin, Texas, October 6, from the effects of chloroform, self-administered.

William A. Hadley, M.D., Meharry Medical College, Nashville, Tenn., 1880, a colored practitioner and teacher, of Nashville, died from apoplexy, October 7.

Alfred T. Cherry, M.D., Bellevue Hospital Medical College, New York City, 1890, of Huntington, W. Va., died suddenly at Oakland, Ky., October 6.

Herbert H. Flagg, M.D., Jefferson Medical College, Philadelphia, 1881, died at his home in Springfield, Mass., from diabetes, October 1, aged 51.

Thomas R. Walker, M.D., College of Physicians and Surgeons, New York, 1853, died at his home in Louisville, Ky., October 1, aged 73.

Hule G. Magee, M.D., Tulane University, New Orleans, La., 1883, was shot and instantly killed in a dispute at Magee, La., September 30.

Herbert J. Hale, M.D., Detroit Medical College, 1875, died at his home in Grass Lake, Mich., from consumption, October 1.

Societies.

COMING MEETINGS.

New York State Medical Association, New York City, Oct. 21-24, 1901.

Medical Society of Virginia, Lynchburg, Nov. 5-7, 1901.

Oklahoma Territory Medical Association, Oklahoma City, Nov. 13, 1901.

Southern Surgical and Gynecological Association, Richmond, Va., Nov. 19, 1901.

Western Surgical and Gynecological Association, Chicago, Dec. 18-19, 1901.

Jacksonville (Ill.) Medical Club.—This organization held its annual meeting, October 5, and elected Dr. Edward Bowe, president; Dr. William K. McLaughlin, vice-president; Dr. David W. Reid, secretary, and Dr. Henry C. Campbell, treasurer.

Lake County (Ohio) Medical Society.—The physicians of Painesville and surrounding towns met at the former place, September 27, and organized a county society, with Dr. David J. Merriman, Painesville, president, and Dr. H. M. Osborne, secretary.

Minnesota Academy of Medicine.—The fifteenth annual meeting of the Academy was held in Minneapolis, October 2. Dr. John T. Rogers, St. Paul, was elected president; Dr. John W. Little, Minneapolis, vice-president, and Dr. Richard O. Beard, Minneapolis, secretary and treasurer.

Perth Amboy (N. J.) Medical Society.—The physicians of Perth Amboy met September 28 and organized a medical society, with the following officers: Dr. John G. Wilson, president; Dr. H. Martyn Brace, vice-president, Dr. Frank C. Henry, secretary, and Dr. William E. Ramsey, treasurer.

Montgomery County (Ill.) Medical Society.—The annual meeting of this Society was held in Hillsboro, October 1. Dr. William H. Cook, Coffeen, was elected president; Dr. Jeremiah C. Wilson, Donnellson, vice-president, and Dr. Joseph M. Trigg, Farmersville, was re-elected secretary and treasurer.

Walla Walla Valley (Washington) Medical Society.—At the meeting of this Society at Walla Walla, September 17, a committee was appointed to memorialize the City Council toward passing an anti-expectoration ordinance. Dr. Yancey C. Blalock was elected secretary of the Society, vice Dr. Smith S. Johnson, resigned.

Harrison County (Texas) Medical Society.—The medical men of the county met at Marshall, September 25, and organized this Society with the following officers: Dr. Samuel F. Vaughan, Jonesville, president; Dr. James H. Taylor, Marshall, vice-president; Dr. Holman Taylor, Marshall, secretary, and Dr. Charles E. Heartsill, Marshall, treasurer.

Fulton County (Ill.) Medical Society.—At the fourth annual meeting of this Society, held in Canton, October 2, the following officers were elected: Dr. Perry H. Stoops, Ipava, president; Drs. William R. Roberts, Norris, and William S. Strode, Lewistown, vice-presidents; Dr. David S. Ray, Jr., Cuba, secretary, and Dr. Frank M. Harrison, Bryant, treasurer.

International Congress of Family Assistance.—Casimir-Perier and T. Roussel have organized an international conference to discuss the details of placing convalescents, mild insane subjects, etc., in families, boarding them in healthy communities, instead of housing them in institutions. There are to be four sections in the congress which convenes at Paris, October 27.

San Angelo District (Texas) Medical Society.—Through the efforts of Dr. Robert L. Greene, San Angelo, this Society was organized, September 28, with the following officers: Dr. Samuel L. S. Smith, San Angelo, president; Drs. Boyd Cornick, Knickerbocker, and Fred F. Tucker, San Angelo, vice-presidents; Dr. Robert L. Greene, San Angelo, secretary, and Dr. Bascom Lynn, treasurer.

French-American New England Medical Association.—In connection with the congress of French-Americans at Springfield, Mass., a medical association was organized with about 200 members on its initial roll, and the following officers were elected: Dr. J. Hector Palardy, Fitchburg, president; Dr. George T. Lamarche, Springfield, secretary and treasurer, and Dr. Henry E. Chaput, Holyoke, corresponding secretary.

Southwestern Tri-State Medical Society.—This Society, composed of members from Texas, Oklahoma and Indian Territory, met at Dallas, Texas, October 1 and 2, for its second annual meeting. The following officers were elected: Dr. John S. Turner, Terrell, Texas, president; Drs. George W. West, Eufaula, I. T., Lawrence T. Smith, Lexington, Okla., and William R. Thompson, Fort Worth, Texas, vice-presidents, and Dr. John O. McReynolds, Jr., Dallas, Texas, secretary and treasurer.

Jersey County (Ill.) Medical Society.—This Society, after a disbandment of several years, was reorganized September 26, at Jerseyville, with the following officers: Dr. John S. Williams, Jerseyville, president; Dr. Jasper Tidball, Grafton, vice-president, and Dr. Augustus K. Van Horne, Jerseyville, secretary and treasurer. The Society was organized in 1856, with Dr. E. A. d'Arcy as president. Dr. A. K. Van Horne, the present secretary, is the only surviving physician who was present at the organization in 1856.

Greene County (Ohio) Medical Society.—The regular meeting of this Society was held at Xenia, Ohio, October 3. Pursuant to the circular letter recently sent out by the American Medical Association, the Society, by unanimous vote, endorsed the laudable efforts being made to cement the medical profession into a united whole. Believing that a National Board of Health, whose head is a cabinet officer, should be instituted, resolutions were adopted lending its encouragement and influence toward accomplishing that end.

Thurber Medical Association.—The forty-eighth annual meeting of this Association was held at Milford, Mass., October 3. The president, secretary, and Dr. William L. Johnson, Uxbridge, were chosen as a committee to represent the Association in connection with the proposed Milford hospital. The following officers were re-elected: Dr. Nathaniel C. B. Haviland, Holliston, president; Dr. Ralph C. Fish, Hopedale, vice-president; Dr. John M. French, Milford, secretary; Dr. Le Grand Blake, Milford, treasurer, and Dr. Christopher D. Albro, Milford, librarian.

Wayne County (Mich.) Medical Society.—This Society held its thirty-sixth annual meeting at the Griswold House, Detroit, October 3. After the meeting the members present became the banquet guests of the retiring president, Dr. John J. Mulheron, who also acted as toastmaster. He reviewed the history of this, the oldest medical society in Michigan, and incidentally argued strongly for the benefit accruing to both the individual and the profession as a whole from active participation in society work. He advocated the publication of a quarterly journal by the Society, and the matter was referred to a committee for consideration. The following officers were elected: Dr. Samuel Bell, president; Dr. Charles C. Yarborough, vice-president; Dr. C. Henri Leonard, treasurer, and Dr. Hugh Mulheron, secretary.

Oregon State Medical Society.—The twenty-eighth annual meeting of this Society was held in Portland, September 25, 26 and 27. The attendance was large, and several prominent physicians from San Francisco, Chicago and Baltimore were present and read papers. The committee appointed to consider the resolution offered by Dr. George F. Wilson providing for the reorganization of the state society on the lines of the American Medical Association, reported that an amendment to the constitution of the state society was necessary to accomplish that end, and that such an amendment had to be offered *one week prior to the meeting of the society*. It was recommended, however, that a delegate and alternate to the National Association be elected. The report was adopted and Dr. Andrew C. Smith, Portland, was elected delegate and Dr. Edward P. Geary, alternate. The election of officers resulted as follows: Dr. Charles J. Smith, Pendleton, president; Dr. Walter T. Williamson, Salem, vice-president; Dr. Alexander D. Mackenzie, Portland, secretary, and Dr. William F. Amos, Portland, member of executive committee.

Utah State Medical Society.—The seventh annual meeting of this Society was held in Provo, October 1 and 2. President John W. Aird, Heber, in his address recommended that the State Society co-operate with the American Medical Association in an effort to unite more closely the medical profession of the United States. He stated that it would be necessary for the State Society to reorganize, so as to make it possible to amalgamate with the national society, and he recommended the election of three members as a committee on reorganization. Drs. John W. Aird, Heber; Andrew J. Hosmer, Salt Lake, and J. C. Elliot King, Salt Lake, were appointed as this committee, and the secretary was instructed to notify the county societies of the contemplated change in organization. A resolution presented favored the establishment of a psycho-physical laboratory by the Department of the Interior. Salt Lake City will be the place of meeting, and the date was changed from the first Tuesday in October to the second Tuesday in May, to conform to the time of meeting of the American Medical Association. The election of officers resulted as follows: Dr. Ira A. E. Lyons, Salt Lake, president; Drs. Philo E. Jones, Salt Lake, and Robert E. Steele, Lehi, vice-presidents; Dr. James N. Harrison, Salt Lake, treasurer, and Dr. George E. Robison, Provo, secretary.

CINCINNATI ACADEMY OF MEDICINE.

Regular Meeting, held September 30.

President Dr. N. P. Dandridge, in the Chair.

Dr. M. L. Heidingsfeld presented two patients of advanced age, who had been suffering from facial epithelioma, but who were now entirely well under local applications of arsenic. He also gave a lantern-slide exhibition showing numerous cases of ignored syphilis.

Excision of the Ileo-Cecal Valve; Tubercular Peritonitis.

Dr. B. Merrill Ricketts presented a patient, a male, aged 28, who had been suffering from partial obstruction of the bowels for eight months. The abdomen was opened on the right side. The ileum was seen to be enormously distended, being fully the size of the cecum; a diverticulum also existed, extending from the cecum, about five inches long and an inch in diameter. The occlusion evidently existed in the valve and the most expedient thing seemed to be the excision of this valve, which was done and an end-to-end anastomosis made with silk sutures. Death occurred ten hours later from exhaustion. Examination of the specimen showed enormous thickening and infiltration of the intestinal membranes constituting the so-called ileo-cecal valve, while both the mucous and serous membranes were studded with small miliary tubercles. Specimen exhibited. Dr. Ricketts also presented a case of multilocular ovarian cyst in a woman of 70, four cases of hematoma of the ovary, a case of purulent salpingitis, and twelve appendectomies, the latter all recovering.

Congenital Elevation of the Scapula.

Dr. Albert Freiberg reported this case: Patient aged ten months. From birth the mother had noted a protrusion over the left collar-bone and that the left side of the child's neck seemed to be much shorter than the right. On examination the neck contours were found to be altogether asymmetrical, but there was no scoliosis. The left scapula was much smaller than the right and evidently elevated. The inferior angle appeared to be about four cm. above the right; the superior angle projected well above the clavicle, indeed was practically subcutaneous. The coracoid process was felt below it and was on a higher plane than the corresponding process of the right side. Passively the scapula was easily moved with the arm, and both actively and passively all movements of the shoulder other than abduction were normal; abduction was limited to ninety degrees. The scapula did not appear to possess any abnormal attachment to the spine, but appeared to be tilted upon its vertical axis in such a way that the superior angle approached more nearly the median line. The thumb of the right hand was unusually small and was not moved to any great extent. Otherwise the child was well developed and nourished. He proposed to watch the child's development and at some future time to remove the superior angle of the scapula. The speaker then stated that in 1899 he had reported another case of elevation or misplacement of the scapula, congenital, in a child, in whom there was in addition a congenital scoliosis and imperfect development of the lower extremity on the affected side. As to etiology he thought it was due entirely to the maintenance that the shoulder holds during fetal life.

Intrauterine Fracture of the Tibia.

The patient, a male, aged four months, in whom from birth there had been noted a deformity of the left leg. There was no family history of deformity. The mother's labor was normal. At about the sixth month of her pregnancy, however, she remembered striking her abdomen against the stair banister, but as no symptoms appeared other than a momentary discomfort, she thought nothing more about it. The child was well developed and nourished, showing absolutely no abnormality except in the left leg. At the middle third of the leg was a hard, angular bend of almost ninety degrees, the apex of the angle presenting forward and inward, and the bone could be easily felt just beneath the skin. The left foot was five to eight inches shorter than the right, but as far as could be ascertained the foot was otherwise normally developed. The left limb was everywhere equal in circumference to the right. The diagnosis of intrauterine fracture of the tibia was made. There was no motion between fragments. Skiagraph showed a fracture of the lower fourth of the tibia. The upper fragment appears to be rounded off, the lower jagged. In May, 1900, an osteotomy was made and the correction of the deformity easily performed. Union did not begin for months, and when finally established the deformity had returned, the patient in the meantime having escaped observation. In September the child was again seen. Although he could bear his weight upon the limb the angular deformity was still very great. At this time two radiographs were made of the leg, one lying on its outer side, the other an antero-posterior view. The first of these shows that while the bones have developed in length and diameter there is no real bony union between the fragments of the tibia. It is also shown that only five tarsal bones are present, the os calcis, astragalus and three of the smaller bones, and articulation was very imperfect. The front view showed that the fibula was present in its entire length, but there seemed to have been a fracture just above the external malleolus. The lower epiphysis of both tibia and fibula seemed to be smaller than they should. The lower fragment of the tibia was seen to be bent not only forward but also outward toward the fibula. The relative size of both bones was otherwise normal. It seemed to the speaker that the case was one of intrauterine fracture of the tibia without defect of the fibula; the case was unusual in that in almost all of the hundred cases reported there was a coincident defect of the fibula as well as an absence of some of the toes or metatarsal and tarsal bones.

Dr. C. A. L. Reed presented a specimen of a large fibroid tumor of the uterus with very marked varicosity of the veins of the broad ligament so that in removing the tumor very severe hemorrhage was encountered.

Rupture of Kidney.

Dr. Joseph Ransohoff showed a radiograph of stone in the bladder of a boy 5 years of age. Not only the size and shape but the lamellæ and nucleus as well could be plainly outlined. Dr. Ransohoff also exhibited a specimen of dermoid tumor, unilocular, weighing twenty-five pounds, removed from a woman 64 years of age. The same speaker also presented two specimens of rupture of the kidney, both removed by lumbar nephrectomy. In the first case the operation had not been performed until the ninth day after injury, the man at the time apparently suffering from intestinal obstruction. In the second case hematuria appeared shortly after injury. By the third day the fever was a prominent symptom and by the fifth day the temperature had risen to 103, with a pulse of 110 to 120. In making the nephrectomy little or no hemorrhage was encountered until the kidney itself was reached, though previous to the operation there was marked swelling in the region of the kidney. The reason for this was found to be because the blood had exuded between the surface of the kidney and its capsule. The upper portion of the kidney was almost completely torn away and from the appearance of the parts it might be very readily surmised that the force of the original injury had shoved the kidney against one of the transverse vertebral processes. The first case had died very promptly after operation but the second was convalescent; during the previous twelve hours, eight days after operation, he had passed 23 ounces of urine.

Painful Stump Following Amputation.

Dr. J. C. Oliver presented this case: The original operation was at the middle third of the thigh, made about ten months ago for a railroad crush. Ten days after amputation he had commenced to suffer severe pain in the stump; often referred to the heel and toes. On operation a false neuroma was found in the cicatrix and pressed against the bone. Several inches of nerve were removed and another false neuroma was discovered and removed a little to one side. He thought that here was also represented a good example of high division of the sciatic nerve.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Fifty-first Annual Meeting, held in Philadelphia, September 24-26, 1901.

(Concluded from page 997.)

THIRD DAY—MORNING SESSION.

Encouragement of County Societies.

Dr. McConnell, New Brighton, offered a resolution recommending the personal visitation to county societies, in which there was evident lack of interest.

Dr. Koenig, Pittsburg, offered a resolution favoring the establishment of a psycho-physical laboratory in the Department of the Interior at Washington for the practical application of physiologic psychology to sociologic and abnormal or pathologic data. The resolution was accepted as read.

Dr. George Erety Shoemaker offered a resolution recommending the compulsory vaccination in schools.

Governor Stone addressed the Society, saying, "The doctors are the great levelers of society in the community. The village doctor, the 'country doctor' if you will call him, has a stronger hold on the pulse of this country than any other man in it."

President McKinley's Case.

Dr. John V. Shoemaker offered a resolution that it was the sense of the Medical Society of the State of Pennsylvania that the physicians and surgeons in attendance upon our late Chief Executive, William McKinley, acted in accordance with the dictates of the best medical and surgical science and that they had the full confidence of the Society.

Address in Surgery—Torsion of Arteries.

Dr. James W. MacFarlane considered the arrest of hemorrhage, particularly that by torsion. He divided torsion into two forms: limited, and free. In so far as the general public is concerned, he said, free torsion is the rule, as limited is not so advantageous. When free torsion fails primarily in a large artery, it is not limited torsion that is required, but the ligature, acupressure and perhaps the complete hemostatic armamentarium of the surgeon. In the matter of time, and the absence of danger of introduction of a foreign body into the wound, torsion is also superior. Another advantage is that an assistant is not required. Torsion in amputations was introduced into the Western Pennsylvania Hospital, Pittsburg, about 1870. Even atheromatous arteries are no bar to its use. The most probable cases in which torsion would not answer are in amputations contiguous to tissues changed by chronic inflammations. Torsion will not prevent secondary hemorrhage and the speaker cited a case in which infection occurred as the cause of secondary hemorrhage; after amputation torsion was again employed and recovery ensued. Exceptional cases were cited in which acupressure was superior to ligature or torsion.

The Operative Treatment of Bladder, Descent and Sacculation.

Dr. George Erety Shoemaker, Philadelphia, said that displacements of the bladder in the female may take place upward, backward, laterally, forward, or downward. Only in the downward direction is sacculation and imperfect evacuation liable to occur frequently, but its secondary effects are very important. He has seen but one case of pathologic forward dislocation. The various displacements with their symptoms were described. Operations above the pubis have little effect upon the bladder position if unsupported by other measures. The plan adopted by the writer was given in detail. Special attention was called to the method of taking up the redundant anterior vaginal wall and supporting the bladder.

The Present Status of the Bottini Operation as a Method of Treatment in Obstructive Hypertrophy of the Prostate Gland, Derived from a Summary of 834 Operations by 48 Operators.

Dr. Orville Horwitz said that contrary to the accepted view that prostatic hypertrophy usually began in individuals over 50 years of age, he believes that the morbid condition commences much earlier, and quotes Dr. L. Bolton Bangs, who agrees with him. Regarding the objection to the Bottini operation held by some, he thought the recorded experience of trustworthy surgeons gave sufficient refutation of the charges that this operation is "uncertain, dangerous and the results obtained are temporary in character." The operation of complete prostatectomy is considered a much more formidable undertaking than that of the Bottini; it is fraught with greater danger, and only to be attempted in rare instances. He thought it worthy of note that the writers objecting to the Bottini operation on the theoretical grounds, had the least practice with the method. In none of the cases under Dr. Horwitz's care has contraction of the vesical outlet, a complication suggested by some, occurred. Pyelitis, though adding to the danger, is not a contra-indication. Four such cases have been operated. Age is not a bar, though the mortality is lower when the resisting power is strong. Statistics of the 843 Bottini operations were given, with a series of conclusions.

Surgery and Its Relation to Neurasthenia.

Dr. G. D. Nutt, Williamsport, stated that in a large number of patients, prominent symptoms of a neurotic character, caused by disease, displaced or irregular muscular action of some organ, can be cured by surgical means. Examples of this class are diseases of the sexual organs, movable kidney, errors of refraction and muscular insufficiency of the recti muscles of the eye. In many cases of neurasthenia correction of abnormal conditions affecting the nervous system must precede the medical treatment. Since pathologic conditions cause nervous symptoms not directly connected with the affected organs, the question was raised, might there not be other diseased organs causing reflex disturbance yet unknown, to account for the large and increasing number of neurasthenics?

Rare Complications in Appendicitis with Their Treatment.

Dr. Ernest Laplace, Philadelphia, presented cases in which these complications had existed. They had a history of a previous acute attack, cured by medical measures, with, however, remaining obscure abdominal pain. Such cases had been erroneously diagnosed as affections of nearly every organ in the abdomen. In view of the difficulty in absolute diagnosis, the necessity of proper surgical intervention was pointed out. Particularly is this necessity apparent when it is realized that pain may be absent in acute appendicitis, or felt at a totally different spot; that fever may be absent, or range to 104 or 105; that a general disturbance and local rigidity are perhaps the only constantly present symptoms of the disease. In every case of appendicitis it should be borne in mind that there was a time when operation would have saved life.

Dr. Joseph Price made the statement that "more people are dying to-day of appendicitis than from an epidemic of smallpox." Chronic cases ought never to occur. Well-marked symptoms, late in the cases, evidenced the fact that the early symptoms should have been detected by a good clinician. He believed the public would come to hold the clinicians thrice responsible for early diagnoses. The complications mentioned in Dr. Laplace's paper should have been prevented by proper recognition of the early conditions.

Dr. Adolph Koenig, Pittsburg, said that he was a general practitioner and as such believed that the general practitioner should use good judgment. He had been in practice twenty-two years and had never yet lost a case of appendicitis which he had had from the beginning. If he saw that a case was not improving under medication he would call in a surgeon, but asserted that a surgeon had no right to operate in a mild inflammatory condition mistaken for appendicitis.

Dr. Mordecai Price reinforced the sentiments of the paper and the expressions of Dr. Joseph Price. His common experience of meeting physicians who had never seen a case of appendicitis, he thought, was explained by the fact that the condition was not recognized. In almost any intraperitoneal inflammation you can safely operate for appendicitis.

Dr. Laplace, in closing, said that inasmuch as the complications are numberless and the diagnosis is often difficult, the patient should be given the benefit of the doubt and the chance of recovery from immediate operation. If the appendix could be purged of its offensive material by drastic measures this should be done. Should the pain reappear after having disappeared, nothing could do justice but the knife. If everybody were rightly treated we would not hear of a case of appendicitis. An "unsuccessful operation" meant that somebody had blundered; the medical man had treated too long, or the surgeon has been a "dirty" surgeon. With the present understanding of appendicitis, the patient should live.

A Case of Perforating Typhoid Ulcer; Laparotomy; Recovery.

Dr. W. L. Rodman, Philadelphia, reported a case of perforating typhoid ulcer in the fifth week, followed by extensive general peritonitis, with an operation thirty-seven hours after the accident. The perforation was found directly under the incision. It was as large as the end of a finger and there was considerable extravasation into the cavity. The opening was rapidly closed with Lembert sutures, and the cavity was flushed with hot saline solution. A large amount of iodoform gauze was introduced at the upper end of the incision, and carried carefully down to and around the perforation, so as to protect the cavity from further possible infection, and also to facilitate drainage. A drainage tube was introduced at the lower end of the wound. Although the case was *in extremis*, with a pulse that could not be counted, the abdomen being like a tightly distended drum, the patient made an unexpected recovery, that is, to-day is perfectly well. The gauze was removed on the tenth day, portions of it having been withdrawn several days earlier. The drainage tube was removed at the end of the sixth day. Time of operation from beginning to end was sixteen minutes. Ether was used as an anesthetic. Dr. Rodman's impressions from this case were: 1. That a case of perforation, even though general peritonitis had begun, should be given the benefit of a laparotomy, if in a hospital where such work can be done with reasonable dispatch. This operation was done at least thirty-seven hours after the perforation. There have been, according to Keen in his monograph, but two successful cases reported where so great a time had elapsed between the accident and the operation, and one of these is doubtful, inasmuch as the perforation was not found. There could be few seemingly more desperate cases than this one, and this, together with a case of general peritonitis following a gunshot wound of the intestine and operated upon successfully fifty-one hours after the accident, has shown that it is rarely too late to give such cases the benefit of surgery. 2. That general anesthesia can be borne even in as grave a condition as this patient was in at the time of operation; she was practically pulseless. Cocain was considered at the time, but the patient was too young to give intelligent co-operation, so necessary for the performance of a laparotomy in the shortest possible time. A third question which might be raised is, how frequently will pathologic perforations of the gut in typhoid fever repair themselves without surgical intervention? Recovery does occasionally take place; the percentage has been estimated to be between 3 and 10 per cent. A much larger number will recover from operation and intervention is indicated. While it may be undoubtedly proper to decline interference in military practice on account of the limited facilities in field hospitals, the rule of action should be just the opposite in civil practice. There is an analogy between traumatic and pathologic perforations of the intestines, not complete, but involving the same general principles, and their treatment should be similar, namely, perform laparotomy as early as is consistent with the existing shock. It is as much a duty to operate in both conditions as it is to tie a bleeding vessel in hemorrhage.

Dr. Joseph Price considered the operation in this case the acme of good surgery.

Dr. Ella B. Everitt, Physician-in-Charge at the Woman's Hospital, said that it had been with the greatest interest that she had watched the case. Drainage from the tube was continued for a week after the operation and drainage from gauze a day or two later. Pus cells were present, but no active organisms were found. She thought the lesson was evident that such patients were entitled to operative interference even though, as was this child, almost moribund. The severity of the attack was so great that it seemed that the child could hardly have lived even without this grave operation. The result was doubly gratifying. The occurrence of a small hemorrhage after the operation was also noted as a second complication. The child rallied well from this and went on to a satisfactory recovery.

Dr. Elizabeth Bundy said the point of interest to her was the range of the persistent temperature. The condition of the child had begun to improve within an hour from the time of the accident.

A Case of Ascites Due to Syphilitic Cirrhosis of the Liver.

Dr. W. J. Roe, Philadelphia, presented the report of this case. Seventeen months after the beginning of ascites, and fourteen months after the first paracentesis, he transplanted the omentum between the perietal peritoneum and the abdominal wall, suturing the omental border of the stomach and colon to the margins of the artificial pocket. Previous to operation, paracentesis was performed 31 times, with an average of 760 ounces and of 14 days' interval. Subsequent to operation, it was performed 21 times; the average was 218 ounces and 12 days' interval. Marked improvement in her general health ensued. After six months her general condition reverted to that at the time of operation and death occurred at the end of eight months. Autopsy showed extensive vascular adhesions, a horseshoe kidney and syphilitic cirrhosis of the liver.

THIRD DAY—AFTERNOON SESSION.

Address in Obstetrics.

Dr. David Funk, Harrisburg, presented the status of several of the more serious obstetric complications and operative procedures. From the standpoint of the general practitioner it was stated that placenta previa would probably remain one of the most disquieting and alarming complications, because there can be no prophylaxis and because of the appalling rapidity with which it destroys life. Symphysiotomy as an operation of election would appear to be gradually displaced by Cesarean section, where the high forceps operation is dangerous. Puerperal septicemia and ectopic gestation were considered in detail. The responsibility of the general practitioner in making an early diagnosis in ectopic gestation, is emphasized. Points of differential diagnosis are as follows: Previous history of sterility; cessation of previously regular menstrual periods; irregular bleeding; colicky pains, and nausea and vomiting. Puerperal eclampsia with its etiology and treatment was considered. As to the etiology, writers are agreed upon a single point—toxemia; in the treatment, serum therapy is regarded as a problem of the future.

The Ultimate Results of Operation for Cancer of the Uterus.

Dr. Charles P. Noble, Philadelphia, emphasized the fact that the greatest problem confronting the medical world is the causation and cure of cancer. In a review of the recent American, French and German literature, it was shown that hysterectomy for cancer of the cervix cures about 10 per cent. of cases; based upon the standpoint of freedom from recurrence at the end of five years, the figures of different surgeons varying from a percentage of zero to twenty of cures. Hysterectomy for cancer of the body of the uterus gives better results, at least 75 per cent. being cured. The writer reports 32 cases of hysterectomy for cancer. Of these 10 have died of recurrence and 1 of pneumonia; 6 cases have been lost sight of, and 2 cases of cancer of the cervix are known to have recurred. The remaining 13 are free from recurrence at the present time. The hope for improvement in results lies in early diagnosis. The fallacy of the doctrine of climacteric hemorrhages is insisted upon, and it is strongly urged that all cases with irregular discharges would be promptly investigated.

Instrumental Perforation of the Uterus.

Dr. Wilmer Krusen, Philadelphia, discussed the conditions which soften the uterus and render the accident liable—carcinoma, anemia, tuberculosis and subinvolution. The different perforations are enumerated with the results. He reported a case of perforation of the uterus at the fundus, in which the omentum had been caught by the curette and drawn through the uterus into the vagina. He saw the case within two hours after the accident and immediately performed celiotomy, with an interrupted recovery. He emphasized the necessity for care, cleanliness and special training in all intra-uterine manipulations.

Some Surprises in the Practice of Obstetrics.

Dr. R. B. Ewing, West Grove, reported a series of obstetric cases interesting from the fact that the unexpected occurred. They were illustrative of the terse expression of one of the most gifted medical authors and teachers of America, who after a lifetime of active service as an obstetrician said: "The practice of obstetrics is full of surprises."

A Parasitic Skin Disease.

Dr. John V. Shoemaker, Philadelphia, exhibited a patient with a peculiar parasitic disease of the skin. Some of its characteristics are its appearance between the ages of 20 and 4 being found by preference upon the anterior portion of the chest, appearing as somewhat irregular patches. It differs from liver spots in that the cause is from without the body, the parasite is conveyed from water or from decayed vegetable material. Sometimes clean linen will contain the germs. He recommended the use of the ordinary corrosive sublimate, the copper salts whether in sulphate or the oleate, and mercury in the form of ointment as the oleate of mercury. He especially emphasized the fact that water should not be used; alcohol, or alcohol in the water should be applied.

A Remarkable Case of Infantile Typhoid of Fetal Origin with Recovery.

Dr. Harry C. Westervelt, Pittsburg, reported the case of a woman seven months pregnant with the third child, who had typhoid fever. The child was delivered at seven months and the mother had a severe course of the fever, but made a good recovery. The child presented the characteristic "old man" appearance of the prematurely born, and weighed 9 pounds, 14 ounces. A temperature of 103.4 F. soon appeared. The fever ran the regular course; the child recovered and presents every appearance of a healthy babyhood.

The Effects of Typhoid Fever on the Nervous System.

Dr. C. C. Hersman, Pittsburg, considered impure air, food, and water the most frequent causes of typhoid fever. In the majority of cases the nervous system is the first attacked by the poison. Not infrequently is the cardiac ganglion and nerve supply of the heart in general supercharged with the poison. The resulting symptoms were given in detail and the convalescence described. Meningitis was mentioned as a grave complication. Two such cases had been treated by the writer within the past two years, one of which recovered. Friedlander, Berlin, was quoted as giving 80 per cent. mortality in typhoid meningitis. Tubercular predisposition in children was mentioned as a fruitful source of typhoid meningitis.

The Value and Importance of Teaching the Fundamental Branches of Medicine from the Standpoint of Their Practical Application.

Dr. Gwilym G. Davis emphasized the fact that teaching should be conducted so that the student understands his subject instead of simply knowing isolated facts. Medicine, it was said, requires too much of a man to enable him to qualify by simply memorizing his subject. Text-books are too statistical and not sufficiently explanatory. Examiners should avoid catch questions and give such that require an understanding of the subject for their answer.

To teach the student to think, not summarize, is the object. The day of the true pedagogue, though long aelayed, is at last dawning.

Ruptured Tubal Gestation and the Physician.

Dr. John M. Fisher, Philadelphia, stated that no form of acute supravaginal pelvic disorder is fraught with more immediate danger to the life of the individual, and yet none in the vast majority of cases is more readily diagnosticated by the experienced gynecologist, and none can be more satisfactorily dealt with by the surgeon than that of ectopic pregnancy. The diagnosis being made, prompt surgery, with but few exceptions, saves the patient. With comparatively few exceptions Dr. Fisher stated that the condition is tubal. The causes are enumerated and the symptoms described. In the light of the perfected methods in surgical technic of the present day the author declares that so-called conservative plans are not to be considered, save in so far as they add to the ever-increasing number of unfortunates to our mortality statistics.

The Kidney Complications of Typhoid Fever.

Dr. James Ely Talley, Philadelphia, in this paper enumerated these complications as albuminuria, acute parenchymatous nephritis, hemorrhagic nephritis and suppurative nephritis. In a series of over 15,000 cases albuminuria occurred in 29 per cent. of cases. Acute parenchymatous nephritis occurred in 3 per cent. of a series of over 18,000 cases with a mortality of from 30 to 50 per cent. Edema is rarely produced, and, if the patient lives, the nephritis almost never becomes chronic; only two such cases are recorded in over 37,000 cases of typhoid. Hemorrhagic nephritis is defined as but an aggravated form of the acute parenchymatous nephritis. It tends strongly toward uremia and has a very large mortality. Suppurative nephritis occurs occasionally, and in these cases typhoid bacilli have been found frequently in the pus or kidney substance at postmortem. If chronic nephritis exists and typhoid intervenes the mortality is very high, over 90 per cent. Albuminuris and acute nephritis occur in the typhoid fever of children with about the same frequency as in adults.

New Method of Performing Nephropexy.

Dr. Henry D. Beyea, Philadelphia, described in full the surgical treatment. The operation is indicated only in those cases where the pathologically mobile kidney produces a complex of symptoms inducing persistent ill-health, and the prescribed medical and mechanical treatment either fails to give relief, or, in the judgment of the physician, is impracticable from the beginning.

Statistics of Typhoid Fever at the Philadelphia Hospital from Jan. 1, to Dec. 1, 1899.

Dr. Herman B. Allyn gave the following statistics: Whole number of cases 184; 135 were males and 49 females; 146 were white and 38 black or mulattoes. The fatal cases numbered 31, a mortality of 16.84 per cent., accounted for largely by the character of the patients and stage of the disease at the time that they were admitted. The patients were made up of the homeless, neglected, dissipated and outcast. Half the fatal cases occurred in negroes, although they constituted only about one-fifth of the whole number of cases. Moreover, only one-fifth of the fatal cases—6—were admitted during the first week, and 23 after the disease had lasted two weeks or more. The causes of death, following Osler's classification, were: Asthenia, 14; intercurrent affections, 9; accidents of the lesion, 8. The Gruber-Widal serum reaction was in accord with the final clinical diagnosis in 88 per cent. of the last 113 cases.

Fracture of the Neck of the Femur—Report of a Case, X-Ray and Specimen.

Dr. Charles E. Thomson, Scranton, reported the case of a patient, aged 62, who sustained a fracture in August, 1899. The patient was bedridden for three months. The shortening amounted to two and one-half inches and the hip was very painful. The operation was described. A solid silver nail, three-sixteenths of an inch in diameter and two and one-half inches long, was driven through the neck and into the head of the femur. The bone flap was replaced and retained by a small silver nail. One year after operation the patient had three-quarters of an inch shortening with 90 degrees free and painless motion. Death occurred from intercurrent disease six months later. The specimen showed firm bony union.

The Pathology, Symptomatology and Treatment of Uremia.

Dr. David Riesman, Philadelphia, presented a very valuable paper devoted to a portrayal of certain less common forms of uremia, namely, uremia associated with hemiplegia, aphasia, mental confusion and insanity. Two points in the treatment were emphasized: bleeding, and sweating. The patient is put into a hot bath of 110 F. for ten minutes, taken out and then put into a hot pack for twenty minutes.

The Etiology of Acute Dysentery.

Dr. Simon Flexner, Philadelphia, said that reports of bacteriologic work in the tropics, Japan, Germany and this country on the etiology of acute dysentery, agree that there is present a septic organism quite peculiar and not found in the body under normal conditions, which seems to be present uniformly when cases of acute dysentery arise. The fact is a matter of importance in respect to the causation of this serious disease and to its prevention. It would appear that the sporadic cases have the same origin as the acute dysentery, and this is of particular importance in the consideration of epidemics. The micro-organism that has been discovered is the organism bearing more or less resemblance to the bacillus of typhoid fever. It occurs in the intestines and can be obtained from the dejecta. It does not occur in health or in other diseases; moreover, the blood serum will give a reaction similar to the Widal reaction. It seems probable, therefore, that, as a result of this work, the septic organism of acute dysentery has been observed. It does not exclude the amoeba. It is possible by the use of this organ to produce serum that may be curative.

In Closing.

Dr. F. B. Ball, the new president, was introduced by Dr. Davis, who welcomed him in a few graceful words. After a short address by Dr. Ball, and a resolution of thanks to all those who had participated in the arrangements for the pleasure of the Society and the success of the meeting, offered by Dr. Alexander Craig, Columbia, the meeting was declared adjourned. The next meeting will be held at Allentown.

CHICAGO ACADEMY OF MEDICINE.

Regular Meeting, held September 13, 1901.

Dr. W. X. Sudduth in the Chair.

Forensic Eye Aspect of Locomotor Ataxia.

Dr. James G. Kiernan presented a paper on this subject. A recent suit against the Chicago Union Traction Company was based upon a diagnosis, made of locomotor ataxia, chargeable to an alleged traumatism occurring fourteen days previous to examination, from an alleged condition of the pupils of which no clear description was given. The diagnostician (a member of the family) had observed the pupils under disadvantageous conditions. From his testimony it would appear that this physician had a crude notion that there was reflex iridoplegia or the Argyll-Robertson pupil. He did not use this term, nor did he describe the procedures he adopted in testing the pupil. No other symptoms of locomotor ataxia were described. The Argyll-Robertson pupil is reflex iridoplegia associated with preserved accommodative mobility, that is, where the pupil is as immovable as a frozen opening, no matter how brightly illuminated or how deeply shaded, but contracts when the finger is approached to the nose. It is found early in locomotor ataxia, but it is also found in paretic dementia, and, as might be expected, in constitutional syphilis. It has even been claimed that it is a diagnostic mark of this last condition. Cases of constitutional syphilis, however, occur quite frequently in which reflex iridoplegia is absent. The position taken by Spitzka, fourteen years ago, that this condition is rarely found in constitutional syphilis, can not now be maintained. A temporary iridoplegia has been noted after railroad accidents and other shocks. Exceptionally, the same pupillary condition has occurred in alcoholism and after diphtheria in the adult. For forensic diagnostic purposes this pupil is not pathognomonic of locomotor ataxia. In the case in which the question was raised, the patient had died before trial. The jury gave less than one-tenth of the statutory limit. If the litigant really had locomotor ataxia, this condition, in Dr. Kiernan's opinion, had preceded the accident and was in all probability then contributory thereto. The man had driven a United States mail wagon on the tracks in front of a street-car. Locomotor ataxia under such conditions could prevent him turning in time.

Dr. Casey A. Wood was of opinion that due care was not always exercised by general practitioners, forensic physicians, or even ophthalmologists in the diagnosis of the Argyll-Robertson pupil. There were so many conditions in which similar states occurred that the diagnosis of locomotor ataxia on this symptom alone was not justified.

Dr. William L. Baum could not agree with certain syphilographers as to the pathognomonic diagnostic value of the Argyll-Robertson pupil in constitutional syphilis. In his experience it was too frequently absent to be regarded as pathognomonic of constitutional syphilis. The fact that it occurred in para-syphiloses, like locomotor ataxia and paretic dementia, did not necessarily demonstrate its value as a symptom of constitutional syphilis.

Dr. Kiernan, in closing, agreed with both Dr. Wood and Dr. Baum, that the pathognomonic value of the Argyll-Robertson pupil in constitutional disease was doubtful.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Treatment of Bronchitis.

Just at this time of year the physician comes in contact with a great number of patients complaining of colds in the head and bronchial catarrh. In the larger cities this is due in a great many instances to the steam-heated apartments. People emerging from a warmer atmosphere are exposed to the cold air and the body becomes chilled, the circulation of the skin is greatly disturbed and the bronchial mucous membrane congested. Those patients suffering from organic heart lesions—especially where mitral lesions are present, producing a congested condition of the pulmonary circuit—are more susceptible to the changes in the atmosphere and the weather. Such conditions in the extremes of life make the prognosis in attack of bronchitis more unfavorable. The treatment must be directed to the different phases of the disease and to the special symptoms which may arise in each individual case. In this connection we wish to emphasize one point in the management of such cases, just as in all cases of infection, and that is—watch the elimination. Elimination should be promoted, not alone by the kidneys but also by the skin, bowels and respiratory tract. In this way the catarrhal turgescence of the mucous membrane is lessened and the process of free secretion is established. The patient should be cautiously and well fed with most digestible food, having warm clothing for the body and proper protection for the chest. In the milder forms of acute bronchitis the following is of service as an expectorant:

℞.	Ammon. carb.	ʒiss	6
	Ammon. bromidi	ʒii	8
	Vini ipecacuanhæ	ʒiv	16
	Aq. menthæ piperitæ q. s. ad	℥iii	96

M. Sig.: One teaspoonful every four hours in water; or:

℞.	Ammon. chloridi		
	Sodii salicylatis, āā	ʒii	8
	Tinct. hyoscyami	ʒv	20
	Mist. glycyrrhizæ co. q. s. ad	℥iii	96

M. Sig.: One teaspoonful every four hours.

If the patient is strong and of a well-marked sthenic type, according to Sir T. Granger Stewart, antimony is a drug of great efficacy, as follows:

℞.	Vini antimonialis		
	Vini ipecacuanhæ, āā	ʒiii	12
	Spts. chloroformi	℥iss	48
	Liq. ammon. citratis q. s. ad	℥vi	192

M. Sig.: One tablespoonful in water every six hours; or:

℞.	Vini antimonialis	ʒii	8
	Spts. etheris nitrosi	℥ss	12
	Liq. ammon. acetatis q. s. ad	℥vi	42

M. Sig.: One tablespoonful in water every six hours. Discontinue when there are symptoms of depression or when free expectoration is established.

In patients presenting signs of feebleness or general weakness, expectorants must be combined with cardiac stimulants, as follows:

℞.	Ammon. carb.	gr. xl	2	66
	Spts. ammon. arom.	ʒvi	24	
	Aq. chloroformi q. s. ad	℥iv	128	

M. Sig.: One tablespoonful every five or six hours; or:

℞.	Tinct. strophanthi	m. xl	2	66
	Spts. ammon. arom.	ʒvi	24	
	Aq. chloroformi q. s. ad	℥iv	128	

M. Sig.: One tablespoonful every six hours.

When the cough is dry and very troublesome at night, so that the patient is unable to sleep, the following containing codein is valuable, which should, however, *never be given* so long as the cough brings up phlegm, but to quiet an aggravating cough, is useful.

℞.	Ammon. carb.	ʒss	2	
	Codeinæ	gr. iv		25
	Tinct. hyoscyami	℥i	32	
	Syr. pruni virg.	℥iss	48	
	Aq. camphoræ q. s. ad	℥iv	128	

M. Sig.: One dessertspoonful every two or three hours.

The free use of expectorants is of advantage in getting rid of particles of dust and foreign substance, which have lodged upon the mucous membrane and act as irritants to the respiratory passages. But we wish to suggest care in the use of anodynes as in the foregoing prescriptions, for too free use of opiates and anodynes impair digestion, produce anorexia, cause constipation and quiet the cough, through which nature is attempting to remove causative factors.

Organic heart lesions, such as mitral regurgitation or obstructive lesions, producing marked congestion and distension of the bronchial vessels, cause a cough and sometimes an acute inflammation. In these cases measures must be taken to support and remove the load by proper cardiac stimulation and free elimination. The patient should be put to bed, so as to *reduce the work of the heart, and the following is recommended* in such conditions:

℞.	Ammon. carb.	gr. xl	2	66
	Infusi digitalis q. s. ad	℥iv	128	

M. Sig.: One tablespoonful in water every five or six hours.

Acting as indirect heart stimulants by dilating the peripheral blood vessels and thus *relieving* the pulmonary congestion and at the same time promoting diuresis, the nitrites are valuable:

℞.	Spts. glonoini (1 per cent.)	m. vi		36
	Spts. etheris nitrosi	ʒiss	6	
	Spts. chloroformi	m. vi		36
	Alcoholis	ʒi	4	
	Aquæ q. s. ad	℥iii	96	

M. Sig.: One tablespoonful every four hours.

Cases of bronchitis, with a history of rheumatism, are best treated by the use of the salicylates in some form, combined, perhaps, with alkalies, as follows:

℞.	Sodii salicylatis		
	Sodii bicarb., āā	ʒii	8
	Syr. glycyrrhizæ co.	℥ss	2
	Aq. foeniculi q. s. ad	℥iv	128

M. Sig.: One tablespoonful in water every four hours.

And in gouty bronchitis colchicum is very valuable, if a proper preparation of this drug can be obtained. But as is *the case in a few other drugs the value of this drug is uncertain*, because of the unreliability of the crude drug used in making the medicinal preparation. The following combination is advised:

℞.	Vini colchici (sem.)		
	Vini antimonialis, āā	ʒiiss-iv	10-16
	Pot. bicarb.	℥ss	16
	Aq. gaultheriæ q. s. ad	℥vi	192

M. Sig.: One tablespoonful four times a day in water.

CHRONIC BRONCHITIS.

The chronic forms of bronchitis require special attention in their treatment, because the degree of activity is not so great as in the acute, but the condition may go on for months or years, being kept up by constant irritation from some source, and this should be sought for and removed if possible. Even greater care must be observed in the clothing, the occupation, the food and the climate. However, in no disease, as Loomis states, is a careful study of each individual case more important. This form of bronchitis occurs in connection with emphysema and diseases of the heart and kidneys in elderly people, and, under such circumstances, the particular cause should be discovered and treated in each case.

Potassium iodid is very often used to good advantage, and has been found very efficient in the majority of cases. The *following formula* is recommended:

℞.	Potassii iodidi	ʒii	8
	Syr. picis liq.	ʒiii	12
	Syr. acidi hydriodici	ʒv	20
	Syr. tolutani q. s. ad	℥iii	96

M. Sig.: *One teaspoonful four times a day in water.*

The aromatic balsams, combined with a mild anodyne, are serviceable if the cough becomes troublesome:

℞.	Balsami copaibæ	
	Pulv. camphoræ, āā	ʒi
	Pulv. acaciæ, q. s.	

M. Ft. capsulæ No. xv. Sig.: One capsule four times a day; or:

℞.	Copaibæ	ʒii	8
	Spts. chloroformi	ʒss	2
	Mucilag. acaciæ	ʒvi	24
	Aq. camphoræ q. s. ad	℥vi	128

M. Ft. mistura. Sig.: *Two tablespoonfuls three times* daily.

Turpentine is sometimes very efficacious, and it may be *given in capsule* or in the form of an emulsion according to Yeo:

℞.	Olei terebinthinæ	ʒii	8
	Mucilag. acaciæ	℥i	32
	Mist. amygdalæ q. s. ad	℥vi	192

M. Ft. mistura. Sig.: Two tablespoonfuls at each dose, every six hours.

Creosote is a valuable preparation *in chronic bronchitis*, and may be given in capsules or in the liquid form as follows:

℞.	Creosoti	ʒss	2
	Aq. chloroformi q. s. ad	℥ii	64

M. Sig.: One teaspoonful four times daily.

As a good stimulating expectorant in cases of chronic bronchial catarrh with profuse, stringy, adhesive mucus, such as is often met with in the aged, the following is recommended by Yeo:

℞.	Ammon. carbonatis			
	Sodii bicarb., āā	gr. xl	2	66
	Tinct. camph. comp.	ʒiv	16	
	Spts. chloroformi	ʒiss	6	
	Infusi senegæ q. s. ad	℥viii	192	

M. Ft. mistura. Sig.: Two tablespoonfuls every five or *six hours, administered in hot water.*

Medicolegal.

Period of Gestation.—The *Supreme Court of Nebraska* says, in the case of Erickson vs. Schmill, that, while there is no absolute rule upon the subject, by general consent, based on extended observation, the usual period of gestation is considered to be about 280 days. This is common knowledge, which courts may be assumed to possess. But that the possible period of embryonic existence is more than 300 days is a fact which courts are not bound to know and act on in the trial of causes. That is to say, courts do not take judicial notice of the fact that the possible period of gestation exceeds ten calendar months.

By Whom Existence of Blood May Be Proved.—It is not necessary, the Supreme Court of Idaho holds, in the murder case of State vs. Rice, that an expert witness, or one skilled in chemistry, be called to prove the existence of blood. The experience of man "from the cradle to the grave" so familiarizes him with the appearance of blood that every witness possessing the full use of his senses, who is competent to testify to other matters, is competent to testify to the existence of blood, or presence of blood stains. It is only where there is doubt as to whether the blood is that of a human being or that of some inferior animal that the aid of chemistry or expert witnesses is necessary.

Physician Calling Wife as Witness to Contract.—The statutes of the State of Washington provide that in an action or proceeding where the adverse party sues or defends as executor, administrator or legal representative of any deceased person, a party in interest or to the record shall not be admitted to testify in his own behalf as to any transaction had by him with, or any statement made to him by, any such deceased person. The case of Whitney vs. Priest was an action by a physician against an administrator for compensation for professional services rendered to the decedent, the wife of the administrator, during her last illness. At the trial, the physician's wife was permitted to testify that she was present with her husband, and that he and the decedent agreed upon the terms of the contract for his surgical treatment of her. This was objected to, as being inhibited by the statute, and the Supreme Court of the State of Washington holds that it was error on account of which the judgment obtained for services must be reversed. It says that the plaintiff and the witness were, as before stated, husband and wife. The professional services which were the subject of contract between the plaintiff and the deceased involved the community interest. The compensation for such services belonged to the community. The physician's wife was interested equally with her husband. She was equally interested in the result of this action. She must necessarily be said, therefore, to be a party in interest. and the transaction and the statements made to the plaintiff physician must equally involve his wife. Hence, the witness fell within the disability of the above provision of the statute, and it was error to admit her testimony as to the transaction and statements made by the deceased to the plaintiff.

Skill Required; Consultation; Diagnosis; Harshness.—The Appellate Court of Illinois, First District, in the malpractice case of McKee vs. Allen, holds that a difference of judgment among medical men as to the best course and method of treatment does not by any means tend to prove that either party is wholly wrong or wholly right. A physician who has given a patient the benefit of his best judgment is not liable for negligence even if his judgment is erroneous, unless the error is so gross as to be inconsistent with reasonable and ordinary skill and care. Again, the court holds that it is the duty of physicians and surgeons to exercise reasonable and ordinary care, skill and diligence in the practice of their profession. To this extent they are liable and no further. They are not required to possess the highest, but reasonable skill. The burden of proof is upon the plaintiff in an action for malpractice to show the want of such care, skill and diligence, and also to show that the injury complained of resulted from failure to exercise these requisites. It can not be said as a matter of law, where a physician recommends a method of treatment recognized and approved by the standard authorities upon medicine and surgery as appropriate to the case in hand, and consults another physician or surgeon who has had experience in the use of such method, and who, after examination of the patient, concurs in his judgment, and the patient submits to the treatment upon such advice, that he has failed to exercise ordinary care, skill or diligence in making such recommendation. If he has not so failed he is not liable. The physician or surgeon is not an insurer of a successful result. Furthermore, the court holds, in this case, that if the diagnosis in question be considered erroneous in calling the disease, which was sciatic rheumatism, chronic, instead of acute, it must still appear that his error in judgment in this respect was not consistent with reasonable and ordinary skill and care; and it must further appear that surgical treatment of acute sciatica was so clearly unwarranted, and such a violation of sound rules of professional practice, as to be also inconsistent with ordinary and reasonable medical skill and care. Then, there was some evidence in this case tending to show that the physician, in the effort to manipulate and straighten the patient's leg, several times resorted to what in her sensitive condition was very painful treatment. But it was apparent that it was employed as a curative measure, and it was not shown to have been injurious. This being all that the court has to say about it is that if his methods in this respect were harsh, the patient was not obliged to retain him in attendance, but was at liberty to employ other medical aid.

AMERICAN.

1. **Spinal Myeloma.**—After reporting a case operated upon by resection of the first four dorsal laminæ and removal of the growth, with microscopic examination of the same, Thomas goes at length into the literature of the subject. The specially interesting feature in his case was the very complete relief of the paraplegia by the operation, the presence also of disassociation of the sensations of temperature, pain and touch such as in syringomyelia in a case of pressure upon the cord from without, as well as the variability in the height of the disturbance of sensation as seen at different examinations and the apparent improvement in the condition of the bones under the use of bone marrow and Coley's toxin treatment. The patient recovered enough to go out and tend to his business, but within a few months he had a return of the pain and swelling in the region of the 6th, 7th and 11th ribs, tenderness to pressure, with rigid spine and difficulty in moving. The further progress of the case is not reported. The reflexes were normal.

4. **Infantile Scurvy.**—Two cases of this condition are briefly reported by Pierson, who uses them as a text for his discussion of the disease. The etiology is doubtful. The most that can be said is that it follows the prolonged use of some unsuitable diet. It generally occurs in children under 2 years, usually from 6 to 15 months of age, and as far as the pathology is concerned from the general practitioner's standpoint, it is simply a hemorrhage with which we have to deal. The earliest and most common symptoms are swelling of the lower end of the diaphysis of the femur; that is an important point in the diagnosis from rhachitis or rheumatism. The swelling is neither hot nor red, as in rheumatism. The diaphysis is tender, which is not the case in rhachitis. The rest of the pathology of the disease consists in anemia, which is probably secondary, due to hemorrhage, and ulcerative stomatitis. Swelling of the gums is not usual in his experience and will not appear with prompt treatment. Hemorrhage may occur from bowels, nose, into the skin or into any of the internal organs. The first symptom noticed in the child is pain, terror of being touched, pain first in the legs, then the arms and back; next swellings appear, but there is no fever. The diagnosis should be easy, the most common error is to call the case rheumatism or to attribute it to a fall or injury. In rhachitis the swelling is epiphyseal, chronic and painless, and there will be a well-marked rosary when it is well developed as in scurvy. Stomatitis and hemorrhages do not occur in rhachitis. Pott's disease is rare under 2 years, and has no swelling of the extremities. Acute anterior poliomyelitis has a febrile onset with later paralysis. Purpura has no swelling of the extremities or stomatitis. Syphilis is more chronic and the swellings less tender. When anyone is called to a child lying with legs drawn up, dreading to be touched, with swelling of the lower end of the diaphyses of the long bones and where there is anemia, with swollen gums, there is no other diagnosis possible than scorbutus. The treatment is simple. Modified, uncooked milk with orange or lemon juice should be given, one-half to one lemon or orange being used daily with fresh beef juice. He usually gives iron, etc., for the debility and anemia. In severe cases the child must be kept quiet on a frame, but he has not had to resort to this.

6.—See abstract in The Journal of October 5, p. 933.

7. **Teaching of Anatomy of the Nervous System.**—Mettler criticises the former methods of teaching nervous anatomy and suggests biologic methods, showing the evolution of the organs from the lower types and uses the spinal cord as an illustration. He shows how this is evolved from the ganglion system of the invertebrate, and that certain portions recognized as belonging to it, are so only by grace of position, but really are parts of the cerebral anatomy. The importance of putting the function and development of the parts before their mere anatomic location enables the student to grasp more intelligently the relations and conditions than would otherwise be the case.

8. **Pre-Medical Education.**—Coulter describes the premedical course adopted in Purdue University, which was devised to furnish a broad and liberal education and give special and extensive training in subjects which underlie primary professional studies, and, by this co-relation of work, to shorten the time required to obtain a university and medical education. The needs of the student beginning a medical course are considered, but he thinks if the professional school and college can make satisfactory allotment of courses common to both, that time, money and strength would be saved.

9.—See abstract in The Journal of July 13, p. 138.

10. **Pistol-Shot Wounds.**—The characteristics of wounds from pistol bullets are described by Curtin, who speaks of the importance of knowing the distance at which the pistol was held from the victim, which can be most accurately determined in most instances. When the pistol is held tightly against the skin, the entrance wound is large as compared to the caliber of the pistol, the edges of the wound are burned and lacerated and there is no surrounding area of blackening, burning or powder stain. If only one or two inches away, the wound is small, but there is a blackened and scorched area around it and the hair is burned. The farther away the pistol is held, up to a certain limit, the more distinct are the imbedded powder stains. The burning of the skin is present up to a range of six inches; it is variable, however, from three to six inches. The presence of powder grains shows that the range has not exceeded five feet, while smoke stains are constant up to a distance of eight inches. If the pistol has been held at some distance, say ten or twenty feet, the entrance wound is small or rounded. There is no blackening around it or any mark of powder stain. The caliber, the length of the barrel, the amount of powder used and its age are all to be considered. In head cases there is very little bleeding at the entrance wound; oozing of brain matter is present in 50 per cent., but both these may be lacking. One should notice the shape of the entrance wound, whether it is distinctly rounded or whether tunneled or grooved. This is important as determining the relative position of the parties. The entrance wound is smaller than the caliber of the bullet, except when the pistol has been fired in direct contact. This is due to the elasticity of the skin. He has rarely seen an exit wound of pistol-shot wounds

of the head. A 22-caliber bullet fractures the skull, it may or may not lacerate the meninges, and rarely enters the cranial cavity. The 32-caliber penetrates the brain, and if it passes through the squamous portion of the temporal bone, it usually produces a comminuted fracture of the bone opposite. It can be best detected by careful external palpation, and sometimes the extraction of the bullet and bone fragments are effected. The bullets of from 38 to 42-caliber penetrate, and in some cases perforate. Accurate anatomic description of the wound of entrance and exit should be made. It is important in giving legal testimony to know the caliber of the bullet. This is determined by accurately weighing the leaden mass and comparing it with standard weights of the different calibers. The caliber sought for will be that one which corresponds with the weight, exceeding by a few grains the weight of the leaden mass. The pistol should always be examined to see if it had recently been discharged. If so the barrel is lined with a black deposit of sulphid of potassium and charcoal, which, when diluted with water, gives a strong alkaline reaction, has the odor of sulphureted hydrogen and a deep brown precipitate forms on the addition of acetate of lead. If the pistol has not been fired for hours or days, this black precipitate changes from the sulphid to the sulphate of potassium, which gives a neutral reaction in a watery solution, and a white precipitate on the addition of acetate of lead. If the time which has elapsed amounts to weeks or months, traces of the oxid of iron as well as of the sulphate of iron will be found. He calls attention to the wounds made by blank cartilages and it is well to remember that they have been known to penetrate to the depth of two inches. From their action in carrying germs and the frequency of tetanus, attention to their removal and treatment of the wound is imperative.

11. **Strangulated Hernia.**—The condition of strangulated hernia, as considered by Pfister, is entirely within the scope of those conditions which the general practitioner can treat, and no more than a fair modern surgical education is required. No rarely-used instruments are needed, and it is so frequent that every physician should inform himself on the technique of the operation, and, with the simple procedures, have successful results in the vast majority of cases. He goes at length into the description of the operation and says in conclusion that there are many conditions, such as advanced age, where a well-adapted truss will suffice, and therefore not all cases of hernia, aside from severe strangulation, should be operated upon.

12. **Tuberculosis.**—The details of the sanatorium treatment of tuberculosis are given by Richer, who lays stress on the importance of rest, including under this term not only the recumbent position, but quiet and the use of bandages to insure long rest to any injured parts, outdoor life, over-feeding, of which he gives the details, and general medical supervision. This last is the most important. He finds that strychnia in 1/30 gr. doses is very useful and creosote is the most reliable internal antiseptic, except where contraindicated by recent hemoptysis. Cough is easily controlled and night sweats disappear with increased nutrition.

16. **Epilepsy and Dyspepsia.**—The close relation between epilepsy and dyspepsia are insisted upon by Aaron, who believes that gastro-intestinal irritation seems to be the cause to which many cases of epilepsy are traceable. The digestive troubles are frequently latent. It is to be recommended in all cases of epilepsy and suspected stomach disorders, that an analysis of the stomach contents and urine should be made. The examination of the patient is not complete unless the digestive organs are also examined.

17. **Social Aspects of Dermatology.**—The subjects considered in Morris' fourth lecture are the pus bacteria of the skin with their consequences, impetigo contagiosa, boils, carbuncles, etc.; anthrax, sycosis, premature grayness, alopecia, acne, vaccination rashes, and tropical parasites; chigos, guinea worm, elephantiasis, etc. Morris believes in the hygiene of the barber shop. He points out that nearly all hair dyes are injurious.

19. **Climate in Nervous Diseases.**—Pearce finds that neurasthenia, chorea and other diseases are badly affected by high altitudes and high winds. He thinks therapeutic climatic results are dependent upon the states of atmospheric pressure and consequent nutritional modifications. High altitudes favor circulation in the periphery and assist nutrition; the trophic functions may advance too rapidly with too great ascents The neurasthenic, therefore, who must appropriate nutrimen slowly on account of the weakened central nervous system, i not suited to high altitudes. Insomnia is benefited by lowe altitudes, as are also chorea, hysteria and most of the functional diseases. Melancholia and depression are helped b high winds with moderate heat to aid in general bodily metabolism. The orgänic diseases dependent *on the* central o peripheral lesions, perverted *function, as pain and sluggis* circulation, will be helped by altitude. A *greater altitude* i desirable for diseases of the central nervous system, and a lesser altitude the desideratum in the cases of *peripheral diseases*, as in neuritis and vasomotor palsies, exophthalmi goiter, etc.

21. **Acute Amygdalitis.**—The conclusions of Floersheim's article are: 1. The tincture of iodin is the most powerful antiphlogistic in inflammations of the throat. 2. Its action i very rapid, relief being often experienced within five minutes. 3. It has relieved the intense inflammation completely when all other throat remedies had absolutely failed to benefit. 4. Its use in sixty-eight cases of acute amygdalitis has been followed by marked benefit in every case. 5. The method of application is simple.

23. **Cancer of the Gall-Bladder.**—According to Manton very little advance has been made in our ability to distinguish the morbid conditions in gall-bladder and bile duct. Cancer of the gall-bladder is not nearly so uncommon as generally supposed, and in many cases where adjoining organs have become secondarily affected, the secondary growth has been credited as primary. The etiology is the most important question, however, and we know at present but one incontestable factor, viz., gallstones, hence the value of early treatment of this condition. Manton reports a case of villous cancer of the gall-bladder with secondary invasion of the adjoining structures, which was operated upon, but died shortly after the operation. The interesting points of the case are the long-continued gastric disorder and secondary infection long before symptoms pointing to the original condition were developed, the sudden appearance of the gall-bladder tumor and the extraordinary size of the stones. When we consider the frequency of gallstones and the fact that they may be promotive of malignancy, their importance must not be overlooked. He also reports a case of cancer of the common bile duct and secondary infection of the common gall-bladder, illustrating the peculiarities of the case. His conclusions are: Although primary cancer of the gall-bladder and bile ducts is rare, recent investigations go to show that it is not so uncommon as generally supposed. As a rule, the onset of the condition is insidious; there are no symptoms developed at an early stage of the disease in either locality, with which we are at present acquainted, which will permit of a positive diagnosis being made. When this is possible the disease has already advanced beyond the helpful intervention of surgery. Fever, having been observed in so many other conditions of the liver and adjacent organs, it is of little or no value as an aid to diagnosis. This same may be said of blood examination. Emaciation is frequently absent, and the patient may remain in apparently good health *until toward the termination of the disease.* The absence of malignant disease elsewhere has no diagnostic significance. The only symptom which may perhaps prove of service in forming a provisional diagnosis of gall-bladder and bile duct malignancy seems to be of gastric origin. In two of the cases reported, and in many cases found recorded in the literature of the subject, disorder of the stomach preceded the local symptoms of cancer. Further investigation along this line is desirable, and all protracted disorders of the stomach which can not be positively referred to other causes should be

viewed with suspicion as a possible indication of beginning malignance in the gall-bladder or bile ducts.

24.—See abstract in THE JOURNAL, xxxvi, p. 1416.

25. **Cleft Palate.**—The importance of the palate rather than the tongue in the production of speech is insisted upon by Makuen, who shows that the function of the former is twofold, and in all voice sounds in which it does not share in the formation of the stop position, it serves as an obturator between the nose and the pharynx, completing the partition between these two cavities, and compelling the outgoing breath to pass through the required particular stop position required for sound. Thus in labials, labiodentals and linguodentals, the sounding breath must pass through the anterior stop position—that is the place where the anterior stop position is made by impeding the moving column of breath in producing the sound; the middle stop position is used in certain articulations and the sound breath must pass through this constricted aperture. The function of the palate is to prevent its passing upward through the nostrils. In the use of the posterior stop position, which is formed by the junction of the velum palati and the dorsum of the tongue, the soft palate serves a double purpose. Its free border rises against the posterior pharyngeal wall, closing the avenue to the nostrils, and its anterior surface, acting in conjunction with the tongue, forms the stop position for the sound. The palate may be defective by perforation of the cleft or paralysis of the muscle. Perforation must be posterior to the stop position in use, to affect speech, though its importance largely depends upon the size. The characteristic speech of cleft palate is well known and the physiology is explainable by the points already elucidated in regard to stop positions. He calls attention to the importance of treating defects of speech early, and if cleft palate is only operated upon after the speech has been acquired the habit will be retained to a greater or less extent, hence the importance of training and education in such cases.

27. **Yellow Fever.**—Waldauer reports experiences which point out to him the probability of transmission of yellow fever by fomites, and, therefore, insists on the importance of continuing the precautions that have formerly been used as regards the transmission of this disease.

30. **Anesthesia and Analgesia.**—The different actions of general anesthetics are here discussed. Local anesthesia is passed by as being rather analgesic than anesthetic. What we understand by anesthesia is producing general intoxication of the body and suspension of consciousness, leaving untouched the vital reflexes of organic life. It is rapid in induction and recovery, and affecting to the least possible degree the tissue, life and function outside of the desired period of suspended sensibility. Search is never ending for the best means of producing such conditions. Magill goes into the physiology of anesthetics to some extent, showing that toxic action increases in the direct ratio to concentration of carbon in the radical of the agent, as does also the rapidity with which anesthesia can be induced. The addition of oxygen to the hydrocarbon molecule probably renders the anesthesia no more toxic, but slower to be induced. The compound formed by a halogen with the organic radical shows greatly increased toxicity, and this toxic factor multiplies directly with the number of elements of the halogen introduced into the molecule, and likewise directly with the relative density or weight of the halogen in question. By reason of the hyperchlorination of its molecule, chloroform is justly proclaimed more toxic than its rival, but an offset compensation is constituted by its correspondingly increased anesthetic energy. The substitution of bromin instead of chlorin in equal numbers of atoms, determines a greater toxicity for the resultant bromid. The halogens of greater atomic weight should increase the toxicity of the molecule so as to render them dangerous in even the minutest doses. The use, however, of monobromid of ethyl is harmless for short administration, but must not be continued; the author gives particular points in regard to the use of this drug. He finds that there is a growing consensus of belief that if chloroform could be relieved from the accidents of primary syncope it would be the best anesthetic. To avoid the point of danger, the cerebral cortex excitement, the English surgeons are employing nitrous oxid to induce the anesthesia. Drs. Hartman and Bourbon and the writer suggested ethyl bromid, and have extensively used this remarkable agent of short narcosis since 1892. The advantages of this method of beginning the anesthesia with ethyl bromid and continuing with chloroform are insisted upon, the importance of perfectly pure ethyl bromid being specially emphasized. For prolongation of unconsciousness, the narcosis induced by this bromid is easily and safely continued with chloroform in very small quantities.

33. **Adrenal Solution.**—Cohen reports a case in which the use of adrenal extract given for asthma seemed to cause excessive edema of the uvula and palate and adjoining regions, inducing also slight edema of the epiglottis. The patient had sprayed the pharynx and nasopharynx vigorously for a prolonged period with suprarenal-chloretone solution. The uvula and palate were scarified, the patient was put at rest, had a drastic purge given, and was advised to use a gargle with lukewarm water aromatized with toilet vinegar. In about an hour the edema began to subside, breathing became easier, and still later the patient became quite comfortable. Traces of edema of the uvula were visible for three or four days. The preparation used was not the one now usually available, but the extract of suprarenal substance with chloretone, which was previously placed upon the market. He has used the adrenal chlorid solution as now prepared with much satisfaction and without any ill effects.

35.—See abstract in THE JOURNAL of October 12, ¶59, p. 1005.

36.—See abstract in THE JOURNAL of September 28, p. 850.

50. **Thrombosis of Central Artery of Retina.**—From a study of a case and the literature, Welt finds that the ophthalmoscopic picture of so-called embolism of the central artery of the retina may be produced by thrombosis of the artery, and that this may take place from the following: 1, endoarteritic changes as in von Michel's case; 2, as a symptom of thrombosis of an entire arterial tract as in Siegrist's case; 3, independently of endarteritic changes, when the blood pressure is reduced and there is a tendency to coagulation of the blood and fatty degeneration of the intima, as in his own case.

51. **Embolism of the Central Artery of the Retina.**—Schweigger questions the frequency of embolism of the central artery, doubt as to which was expressed by him more than thirty years ago, but only in recent years has the anatomic basis been given for these cases of sudden blindness by the demonstration of endarteritis with narrowing of the lumen, which accompanies various forms of retinal diseases. The view that sudden blindness with cloudiness of the disc and retina depends upon embolism arose only because the appearance that was previously termed infiltration, later was termed embolism. Graefe's case teaches that embolism is not immediately followed by cloudiness. On the contrary, the narrowing of the retinal arteries from endarteritis must needs cause slowing of the blood count, which may produce infiltration. This peculiar cloudiness of the retina may develop without circulatory disturbance, as he shows by a case of his own, which he thinks was probably caused by a shot striking the optic nerve.

52. **Bell's Phenomenon.**—This phenomenon, discovered by Sir Charles Bell in 1823, consists in associated movement of the eyeball, cornea turning up and in and then up and out, where it remains while the lids are held closed. It is not a pathologic phenomenon, though it was originally held as such from experience in cases of facial paralysis. The cause of it has not been fully cleared up. Nagel has investigated the matter himself and gives the opinion that the phenomenon is really a normal reflex. Whether we must not concede a simultaneous innervation of the orbicularis and the elevators of the eye dependent upon cortical associations, as has been assumed by Mendel and Negro, is not definitely decided. He thinks it is not impossible that Bell's movement in ordinary closure of the

of the head. A 22-caliber bullet fractures the skull, it may or may not lacerate the meninges, and rarely enters the cranial cavity. The 32-caliber penetrates the brain, and if it passes through the squamous portion of the temporal bone, it usually produces a comminuted fracture of the bone opposite. It can be best detected by careful external palpation, and sometimes the extraction of the bullet and bone fragments are effected. The bullets of from 38 to 42-caliber penetrate, and in some cases perforate. Accurate anatomic description of the wound of entrance and exit should be made. It is important in giving legal testimony to know the caliber of the bullet. This is determined by accurately weighing the leaden mass and comparing it with standard weights of the different calibers. The caliber sought for will be that one which corresponds with the weight, exceeding by a few grains the weight of the leaden mass. The pistol should always be examined to see if it had recently been discharged. If so the barrel is lined with a black deposit of sulphid of potassium and charcoal, which, when diluted with water, gives a strong alkaline reaction, has the odor of sulphureted hydrogen and a deep brown precipitate forms on the addition of acetate of lead. If the pistol has not been fired for hours or days, this black precipitate changes from the sulphid to the sulphate of potassium, which gives a neutral reaction in a watery solution, and a white precipitate on the addition of acetate of lead. If the time which has elapsed amounts to weeks or months, traces of the oxid of iron as well as of the sulphate of iron will be found. He calls attention to the wounds made by blank cartilages and it is well to remember that they have been known to penetrate to the depth of two inches. From their action in carrying germs and the frequency of tetanus, attention to their removal and treatment of the wound is imperative.

11. **Strangulated Hernia.**—The condition of strangulated hernia, as considered by Pfister, is entirely within the scope of those conditions which the general practitioner can treat, and no more than a fair modern surgical education is required. No rarely-used instruments are needed, and it is so frequent that every physician should inform himself on the technique of the operation, and, with the simple procedures, have successful results in the vast majority of cases. He goes at length into the description of the operation and says in conclusion that there are many conditions, such as advanced age, where a well-adapted truss will suffice, and therefore not all cases of hernia, aside from severe strangulation, should be operated upon.

12. **Tuberculosis.**—The details of the sanatorium treatment of tuberculosis are given by Richer, who lays stress on the importance of rest, including under this term not only the recumbent position, but quiet and the use of bandages to insure long rest to any injured parts, outdoor life, over-feeding, of which he gives the details, and general medical supervision. This last is the most important. He finds that strychnia in 1/30 gr. doses is very useful and creosote is the most reliable internal antiseptic, except where contraindicated by recent hemoptysis. Cough is easily controlled and night sweats disappear with increased nutrition.

16. **Epilepsy and Dyspepsia.**—The close relation between epilepsy and dyspepsia are insisted upon by Aaron, who believes that gastro-intestinal irritation seems to be the cause to which many cases of epilepsy are traceable. The digestive troubles are frequently latent. It is to be recommended in all cases of epilepsy and suspected stomach disorders, that an analysis of the stomach contents and urine should be made. The examination of the patient is not complete unless the digestive organs are also examined.

17. **Social Aspects of Dermatology.**—The subjects considered in Morris' fourth lecture are the pus bacteria of the skin with their consequences, impetigo contagiosa, boils, carbuncles, etc.; anthrax, sycosis, premature grayness, alopecia, acne, vaccination rashes, and tropical parasites; chigos, guinea worm, elephantiasis, etc. Morris believes in the hygiene of the barber shop. He points out that nearly all hair dyes are injurious.

19. **Climate in Nervous Diseases.**—Pearce finds that neurasthenia, chorea and other diseases are badly affected by high altitudes and high winds. He thinks therapeutic climatic results are dependent upon the states of atmospheric pressure and consequent nutritional modifications. High altitudes favor circulation in the periphery and assist nutrition; the trophic functions may advance too rapidly with too great ascents. The neurasthenic, therefore, who must appropriate nutriment slowly on account of the weakened central nervous system, is not suited to high altitudes. Insomnia is benefited by lower altitudes, as are also chorea, hysteria and most of the functional diseases. Melancholia and depression are helped by high winds with moderate heat to aid in general bodily metabolism. The organic diseases dependent on the central or peripheral lesions, perverted function, as pain and sluggish circulation, will be helped by altitude. A greater altitude is desirable for diseases of the central nervous system, and a lesser altitude the desideratum in the cases of peripheral diseases, as in neuritis and vasomotor palsies, exophthalmic goiter, etc.

21. **Acute Amygdalitis.**—The conclusions of Floersheim's article are: 1. The tincture of iodin is the most powerful antiphlogistic in inflammations of the throat. 2. Its action is very rapid, relief being often experienced within five minutes. 3. It has relieved the intense inflammation completely when all other throat remedies had absolutely failed to benefit. 4. Its use in sixty-eight cases of acute amygdalitis has been followed by marked benefit in every case. 5. The method of application is simple.

23. **Cancer of the Gall-Bladder.**—According to Manton very little advance has been made in our ability to distinguish the morbid conditions in gall-bladder and bile duct. Cancer of the gall-bladder is not nearly so uncommon as generally supposed, and in many cases where adjoining organs have become secondarily affected, the secondary growth has been credited as primary. The etiology is the most important question, however, and we know at present but one incontestable factor, viz., gallstones, hence the value of early treatment of this condition. Manton reports a case of villous cancer of the gall-bladder with secondary invasion of the adjoining structures, which was operated upon, but died shortly after the operation. The interesting points of the case are the long-continued gastric disorder and secondary infection long before symptoms pointing to the original condition were developed, the sudden appearance of the gall-bladder tumor and the extraordinary size of the stones. When we consider the frequency of gallstones and the fact that they may be promotive of malignancy, their importance must not be overlooked. He also reports a case of cancer of the common bile duct and secondary infection of the common gall-bladder, illustrating the peculiarities of the case. His conclusions are: Although primary cancer of the gall-bladder and bile ducts is rare, recent investigations go to show that it is not so uncommon as generally supposed. As a rule, the onset of the condition is insidious; there are no symptoms developed at an early stage of the disease in either locality, with which we are at present acquainted, which will permit of a positive diagnosis being made. When this is possible the disease has already advanced beyond the helpful intervention of surgery. Fever, having been observed in so many other conditions of the liver and adjacent organs, it is of little or no value as an aid to diagnosis. This same may be said of blood examination. Emaciation is frequently absent, and the patient may remain in apparently good health until toward the termination of the disease. The absence of malignant disease elsewhere has no diagnostic significance. The only symptom which may perhaps prove of service in forming a provisional diagnosis of gall-bladder and bile duct malignancy seems to be of gastric origin. In two of the cases reported, and in many cases found recorded in the literature of the subject, disorder of the stomach preceded the local symptoms of cancer. Further investigation along this line is desirable, and all protracted disorders of the stomach which can not be positively referred to other causes should be

viewed with suspicion as a possible indication of beginning malignance in the gall-bladder or bile ducts.

24.—See abstract in THE JOURNAL, xxxvi, p. 1416.

25. **Cleft Palate.**—The importance of the palate rather than the tongue in the production of speech is insisted upon by Makuen, who shows that the function of the former is twofold, and in all voice sounds in which it does not share in the formation of the stop position, it serves as an obturator between the nose and the pharynx, completing the partition between these two cavities, and compelling the outgoing breath to pass through the required particular stop position required for sound. Thus in labials, labiodentals and linguodentals, the sounding breath must pass through the anterior stop position—that is the place where the anterior stop position is made by impeding the moving column of breath in producing the sound; the middle stop position is used in certain articulations and the sound breath must pass through this constricted aperture. The function of the palate is to prevent its passing upward through the nostrils. In the use of the posterior stop position, which is formed by the junction of the velum palati and the dorsum of the tongue, the soft palate serves a double purpose. Its free border rises against the posterior pharyngeal wall, closing the avenue to the nostrils, and its anterior surface, acting in conjunction with the tongue, forms the stop position for the sound. The palate may be defective by perforation of the cleft or paralysis of the muscle. Perforation must be posterior to the stop position in use, to affect speech, though its importance largely depends upon the size. The characteristic speech of cleft palate is well known and the physiology is explainable by the points already elucidated in regard to stop positions. He calls attention to the importance of treating defects of speech early, and if cleft palate is only operated upon after the speech has been acquired the habit will be retained to a greater or less extent, hence the importance of training and education in such cases.

27. **Yellow Fever.**—Waldauer reports experiences which point out to him the probability of transmission of yellow fever by fomites, and, therefore, insists on the importance of continuing the precautions that have formerly been used as regards the transmission of this disease.

30. **Anesthesia and Analgesia.**—The different actions of general anesthetics are here discussed. Local anesthesia is passed by as being rather analgesic than anesthetic. What we understand by anesthesia is producing general intoxication of the body and suspension of consciousness, leaving untouched the vital reflexes of organic life. It is rapid in induction and recovery, and affecting to the least possible degree the tissue, life and function outside of the desired period of suspended sensibility. Search is never ending for the best means of producing such conditions. Magill goes into the physiology of anesthetics to some extent, showing that toxic action increases in the direct ratio to concentration of carbon in the radical of the agent, as does also the rapidity with which anesthesia can be induced. The addition of oxygen to the hydrocarbon molecule probably renders the anesthesia no more toxic, but slower to be induced. The compound formed by a halogen with the organic radical shows greatly increased toxicity, and this toxic factor multiplies directly with the number of elements of the halogen introduced into the molecule, and likewise directly with the relative density or weight of the halogen in question. By reason of the hyperchlorination of its molecule, chloroform is justly proclaimed more toxic than its rival, but an offset compensation is constituted by its correspondingly increased anesthetic energy. The substitution of bromin instead of chlorin in equal numbers of atoms, determines a greater toxicity for the resultant bromid. The halogens of greater atomic weight should increase the toxicity of the molecule so as to render them dangerous in even the minutest doses. The use, however, of monobromid of ethyl is harmless for short administration, but must not be continued; the author gives particular points in regard to the use of this drug. He finds that there is a growing consensus of belief that if chloroform could be relieved from the accidents of primary syncope it would be the best anesthetic. To avoid the point of danger, the cerebral cortex excitement, the English surgeons are employing nitrous oxid to induce the anesthesia. Drs. Hartman and Bourbon and the writer suggested ethyl bromid, and have extensively used this remarkable agent of short narcosis since 1892. The advantages of this method of beginning the anesthesia with ethyl bromid and continuing with chloroform are insisted upon, the importance of perfectly pure ethyl bromid being specially emphasized. For prolongation of unconsciousness, the narcosis induced by this bromid is easily and safely continued with chloroform in very small quantities.

33. **Adrenal Solution.**—Cohen reports a case in which the use of adrenal extract given for asthma seemed to cause excessive edema of the uvula and palate and adjoining regions, inducing also slight edema of the epiglottis. The patient had sprayed the pharynx and nasopharynx vigorously for a prolonged period with suprarenal-chloretone solution. The uvula and palate were scarified, the patient was put at rest, had a drastic purge given, and was advised to use a gargle with lukewarm water aromatized with toilet vinegar. In about an hour the edema began to subside, breathing became easier, and still later the patient became quite comfortable. Traces of edema of the uvula were visible for three or four days. The preparation used was not the one now usually available, but the extract of suprarenal substance with chloretone, which was previously placed upon the market. He has used the adrenal chlorid solution as now prepared with much satisfaction and without any ill effects.

35.—See abstract in THE JOURNAL of October 12, ¶59, p. 1005.

36.—See abstract in THE JOURNAL of September 28, p. 850.

50. **Thrombosis of Central Artery of Retina.**—From a study of a case and the literature, Welt finds that the ophthalmoscopic picture of so-called embolism of the central artery of the retina may be produced by thrombosis of the artery, and that this may take place from the following: 1, endoarteritic changes as in von Michel's case; 2, as a symptom of thrombosis of an entire arterial tract as in Siegrist's case; 3, independently of endarteritic changes, when the blood pressure is reduced and there is a tendency to coagulation of the blood and fatty degeneration of the intima, as in his own case.

51. **Embolism of the Central Artery of the Retina.**—Schweigger questions the frequency of embolism of the central artery, doubt as to which was expressed by him more than thirty years ago, but only in recent years has the anatomic basis been given for these cases of sudden blindness by the demonstration of endarteritis with narrowing of the lumen, which accompanies various forms of retinal diseases. The view that sudden blindness with cloudiness of the disc and retina depends upon embolism arose only because the appearance that was previously termed *infiltration*, later was termed embolism. Graefe's case teaches that embolism is *not* immediately followed by cloudiness. On the contrary, the narrowing of the retinal arteries from endarteritis must needs cause slowing of the blood count, which may produce infiltration. This peculiar cloudiness of the retina may develop without circulatory disturbance, as he shows by a case of his own, which he thinks was probably caused by a shot striking the optic nerve.

52. **Bell's Phenomenon.**—This phenomenon, discovered by Sir Charles Bell in 1823, consists in associated movement of the eyeball, cornea turning up and in and then up and out, where it remains while the lids are held closed. It is not a pathologic phenomenon, though it was originally held as such from experience in cases of facial paralysis. The cause of it has not been fully cleared up. Nagel has investigated the matter himself and gives the opinion that the phenomenon is really a normal reflex. Whether we must not concede a simultaneous innervation of the orbicularis and the elevators of the eye dependent upon cortical associations, as has been assumed by Mendel and Negro, is not definitely decided. He thinks it is not impossible that Bell's movement in ordinary closure of the

lids is a reflex, depending upon the closure, but in spasmodically intentional closure of the lids the excitation may reach some higher point of the central nervous system, possibly the cortex.

60. **Uterine Fibroids.**—Noble gives an analysis of 218 cases of fibroids tabulating their complications, which are numerous; some of them fatal, some threatening the life of the patient and some leading to permanent invalidism. He has not seen any similar tables of complications to offer a basis of comparison, therefore he is not sure whether his experience is the same as that of others. Accounts are given of some notable cases; his experience does not support the doctrine that fibroids disappear with the menopause, and he thinks this is not to be expected. In the tables no mention is made of adhesions which were present in numerous cases. The most characteristic symptom of patients suffering from these tumors is anemia, which in some exists in the highest degree. In one case in which hysterectomy was performed the anemia was high—hemoglobin 10 per cent. and red cells 2,325,000. The results were favorable, and, comparing the mortality of fibroids and complications—33 per cent.—with the mortality of the operation—with less than 10 per cent.—he thinks the results very much in favor of operation. The proper treatment of fibroid tumors is their early removal; there may be exceptions to the rule, and each case must be decided upon its own merits. According to his own experience, small multinodular, subperitoneal fibroids in women over 40 are less apt to grow and cause trouble; submucous, and intramural growths in younger women are more apt to develop and need operation. He has met with but few fibroids that do not produce symptoms. Therefore he thinks the percentage of cases is small in which operation is not indicated.

61. **Ureterocystotomy.**—Smith has experimented with the lesions of the urinary bladder and the ureters under tension as would be the case from the resection of a ureter with a loss of length. He has experimented on the cadaver and living dogs. The oblique operation referred to below is as follows: "An incision of an inch long is made, in an antero-posterior direction, through the bladder peritoneum; this is dissected to each side, exposing the underlying musculosa. At the distal end an opening of sufficient size to receive the ureter is made into the bladder. A fine silk ligature is now passed through the muscular wall of the bladder, from one-quarter to three-eighths of an inch above the opening; this also grasps the ureteral wall, penetrating the lumen, at such a distance from the end of the ureter as to permit it later to enter the bladder. Before tying this a second suture is passed in a similar manner just above the bladder opening. After these are tied the end of the ureter is inserted into the bladder, and two additional sutures are applied in a like manner at the edge of the bladder opening, firmly grasping the bladder wall and penetrating the ureteral lumen. The reflected peritoneum is now drawn over the ureter by interrupted silk sutures, placing the ureteral sutures extraperitoneal." The conclusions which he reaches are as follows: "1. It is practicable to anastomose the ureter to the bladder under tension, if the two are securely held in apposition till firm adhesions form. 2. This relation can be attained by the above-described method of oblique implantation. 3. An additional length of one-half to one inch can be safely obtained by traction on the ureter. 4. The presence of a ligature in the lumen of the ureter is not injurious, because Nature conceals it behind new epithelium."

62. **Conservation of Ovaries.**—Beyea reports a case in which conservative operation was performed, leaving the lower portion of the uterus, perhaps 1 or 2 centimeters, in the patient, who had been suffering from large myoma; he also notices other cases in the literature. He suggested the following questions as regards the practicability of this conservative hysteromyomectomy: 1. Of what value are ovulation and menstruation when the possibility of conception is destroyed? He believes that this function of the ovaries is a very important matter whether the uterus exists or not. 2. In what frequency will pathologic changes develop if the ovaries are left in position? He has not seen much to indicate their probability and considers they will be extremely rare. Secondary atrophic changes may take place, but he thinks will probably not occur. In the four cases reported by Abel there was a gradual atrophy or diminution in size, but there were no symptoms of menopause, and the molimina menstrualia were normal. There is, he thinks, no sufficient technical reason why the operation should not be performed nor any cause why it will be more dangerous than an early hysteromyomectomy.

75. **Uterine Hydatids.**—A case of this rare condition is reported by Smith, who defines it as a pathologic condition of the chorion characterized by the existence in the uterine cavity of a large number of translucent vesicles, containing a clear limpid liquid, which closely resembles the liquor amnii. A peculiarity is its proneness to penetrate the uterine walls. The causes are noticed; it begins usually in the multiparæ at the close of the child-bearing period, and is characterized by symptoms indicating the mechanical pressure of the growth, hemorrhage, etc. The prognosis is determined by the frequency and violence of the attending hemorrhage. Immediate evacuation of the uterine contents is always advisable if the diagnosis is established before the appearance of labor.

78. **Cystocele.**—The operation here described by Taulbee is that of dissecting or stripping of the perineum from the bladder by a vaginal operation, packing with gauze, then opening the abdomen and suspending the bladder to the abdominal wall by sutures passing into the muscular tissue but avoiding the mucosa. The difficult feature of the operation consists in the properly divesting the bladder of its peritoneal covering and reapproximation of the same, properly inserting the ligatures and denuding the area which it is desired should adhere to the pelvic or abdominal fascia. Care should be taken to avoid all arteries and veins and not to injure the mucous or submucous layers of the bladder. The ligatures must be so adjusted that tension will be uniform and the denuded surface hold the peritoneum to the abdominal wall. The ureters must not be disturbed. The point of entrance and exit of the needle must conform to the size of the distended bladder, which will vary in different subjects. In another operation which he promises to report in the future the vaginal vault was not opened, the uterus and bladder were suspended through the abdominal opening and drainage carried on through this wound; the result, however, was not so satisfactory. He claims priority in his operation, as he has not found anything in regard to it in the literature.

80. **Infection in Abortion.**—From a review of the literature Porter holds the evidence warrants the following conclusions: "1. That acute infections of the genitalia frequently cause abortion. 2. That many attempts to produce abortion criminally, succeed only because of the infection introduced in the attempt. 3. That habitual abortion is usually the result of chronic infection. 4. That, other reasons aside, examinations of pregnant women should be conducted with careful attention to asepsis for fear of inducing abortion. 5. That aborting women should be regarded by the physician as infected women and that he should as carefully disinfect himself after administering to them as he would after attending cases of puerperal infection, etc., before undertaking other obstetric or surgical cases."

85. **Gastric Ulcer.**—Davis describes the symptoms of gastric ulcer, calling attention to the necessity of examination of the stomach contents, and the recognized need of greater care in studying the urine in these cases, paying attention to the reduced acidity and well-marked alkalinity wave after meals. Also the blood examination; the rare cases where there is a hyperchlorhydria may create difficulties, and, when the tumor can not be felt, a diagnosis may be impossible. He goes into the dietetic and medicinal treatment of these cases, making the rest and milk diet the essentials; a guarded prognosis should always be given. In conclusion he suggests the need of laboratories and the advisability of medical societies organizing and supporting these, so that their advantages can be obtained by the practitioner in general.

87. **Appendicitis.**—Davis ends his paper as follows: "In all cases of chronic appendicitis and those who have had one or more severe attacks, or two or more light attacks, an operation is indicated. 2. In simple cases of appendiceal colic without severe pain, no vomiting, no fever and no rise of pulse rate, immediate operation is not imperative, though the appendix should be removed at the earliest convenience after the attack is over. 3. In acute attacks seen during the first forty-eight hours, accompanied by persistent vomiting, severe pain and rigidity of the right rectus abdominis, immediate operation should be done whether there be much fever or rise of pulse rate or not. 4. In patients seen after the third day of the attack (*a*), if distinctly convalescent, operation may be postponed until the acute symptoms fully subside; (*b*), if not distinctly convalescent, but with an amelioration of all the acute symptoms, immediate operation should be done; the operation may be delayed if the patient can be closely watched and is in suitable surroundings for an immediate operation should there be an exacerbation of the symptoms; (*c*), in patients becoming progressively worse, but not yet moribund or nearly so, operation done at once will save more patients than can be saved by other means; (*d*), moribund patients should be allowed to die without operation."

88.—This article appeared in The Journal, xxxvi, p. 1157.

95. **Sulphid of Calcium.**—Earp finds that this is a valuable remedy in scrofulous cases and in the treatment of boils, felons and acne, and is an adjuvant to mercury and iodid of potassium in specific cases. He quotes letters from Dr. H. A. Hare, who endorses the remedy, and thinks it does good where there is a tendency to the development of pustular conditions of the skin; he also quotes from Dr. D. M. R. Culbreth, who speaks highly of it in scrofulous or glandular conditions when used with discretion and judgment. It should not be used too generally. He thinks it a valuable agent in knowing hands. Dr. G. F. Butler has had but little personal experience, but is convinced that it is an efficient remedy in the class of cases in which it has been recommended by Earp.

97.—See abstract in The Journal, xxxvi, p. 1726.

105. **Apex Pneumonia.**—From a study of cases, including the statistics of Pye Smith and others, Cordell concludes that: "Acute lobar pneumonia affecting the apex is about one-third as frequent as that affecting the base, and of the two apices, the right is affected about three times as often as the left. Involvement of one apex and the opposite base is very rare, and that of the two apices still rarer. Apex pneumonia is not rare in early life, and the relative involvement of the upper and lower lobe corresponds with that in the adult. The general mortality of the apex and basal forms is about the same. Involvement of one apex and the other base does not appear to be a fatal form of double pneumonia, apart from complications. The mortality of uncomplicated apical disease in the child is almost nil. Delirium is not an infrequent prognostic symptom at any age. Intemperance and hyperpyrexia do not increase the relative mortality at the apex. Pericarditis is a fatal complication, and Bright's disease and bronchitis render the prognosis much graver. Delirium is not a more frequent or marked symptom in apex cases in the adult, and seems to occur more often in cases with complications than in the basal form. Intemperance, which is the chief cause of this symptom, does not seem to increase its relative frequency at the apex. There is no positive evidence that delirium is more frequent or prominent in the young with apical pneumonia. Pericarditis is relatively more frequent in apex cases. The same appears to be the case with otitis media. It is not evident in the case of icterus, hyperpyrexia, endocarditis, meningitis, pleurisy, diabetes, or empyema. Gangrene is doubtful. There is no reason (other than site) why apex pneumonia in the adult should be more readily overlooked. Phthisis is rare in connection with acute lobar pneumonia, and the apex form involves no tendency to eventuate in it. Cases of apex pneumonia, even in the adult, sometimes assume the mildest symptomatology."

111.—See abstract in The Journal of September 14, p. 711.

118. **Enuresis.**—Barbour recommends the use of boracic acid in enuresis. He was led to employ it from his desire to render the urine less alkaline and more antiseptic. Later he added salol to the boric acid and the results have been most gratifying, so that it has become his routine treatment for enuresis. Abnormally contracted bladder and conditions like malnutrition, etc., can not be thus benefited. He does not give the dosage in which he has employed the drugs in these cases.

119. **Hydrotherapy in Neurasthenia.**—The method here advocated by Sinkler is as follows: The patient is placed in a hot-water cabinet until perspiration begins, then given the circular or so-called needle bath for one minute, beginning with a temperature of 95, gradually reducing it to 85 with pressure of 20 pounds. The Scotch douche is then applied to the spine, alternating hot and cold water, at a temperature of 105 and 80, under the same pressure. The treatment usually first lasts only 25 or 30 seconds. After a few days the pressure is increased to 25 or 30 pounds, and the extremes of temperature used are much greater, alternating from between 110 and 70. After about two weeks' treatment, in addition to the circular and Scotch douche, the fan douche may be used for the body, abdomen and extremities. The patient's condition should be carefully watched, and if reaction is not good, go slowly in reducing the temperature and increasing the pressure. It is his custom to have the pulse, temperature and respiration taken before and after the treatment, and have the patient weighed also before and after. After the bath, brisk friction is applied with a warm, dry towel, and a few minutes' general surface massage is given; then the patient is sent out for a walk. Taking exercise after the bath is a point which Dr. Baruch insists upon as it promotes reaction. Hydrotherapy does not agree with all neurasthenics and each case should be treated individually and carefully watched. But if the different baths produce an unsatisfactory result it is best to begin with the wet pack and sponging of the spine witth warm and cold water at home. In some cases the drip sheet does more good than either the wet pack or hot bath. Insomnia is a condition greatly benefited by this treatment, also melancholia and other conditions.

125. **Gallstones.**—McCalla reports a case in which after cholecystotomy followed by fistula and apparent obstruction of the gall duct from inflammation due to impacted stones which were removed, he waited until after the peritoneal cavity was sufficiently isolated from the drainage wound and used hot water, temperature 130 F., at a pressure of several feet for some seconds to force an opening in the duct, with success. Later he carried the water pressure as high as twelve feet. The result was that the bile escaped into the intestines, the drainage wound healed up, and the patient recovered her health.

130. **Tuberculosis.**—Gibbes says that he would not be surprised if Koch had a still more startling statement yet, and the one in regard to human and bovine tuberculosis was somewhat of a pioneer balloon. It must be remembered that he has never gone so far as some of his disciples, and that years ago he admitted having seen cases where no tubercle bacilli could be found. Gibbes himself believes that there are two conditions which go under the name of consumption and which should have entirely different treatment. The first is purely inflammatory, beginning as a bronchitis, extending into the lungs as bronchial pneumonia and forming a consolidation varying according to the intensity of the inflammation and the number of infected bronchioles. If the vitality of the patient is low or the intensity of the inflammatory process great, so as to overcome the natural resistance of the part, necrosis results, and after a while a cavity is formed. Careful study of these facts has proven that they are purely inflammatory from first to last and bacteriologic examination fails to reveal the tubercle bacilli in sections of any consolidation of the lungs until these organs begin to break down; then they are usually pres-

ent in large numbers. He asks when these cases become tubercular; he feels sure that it is the stage when the tubercle bacilli appeared and that was when the diseased process had destroyed so much lung that the patient would have died anyway. He maintains that over 50 per cent. of lung cavities are due to bronchial pneumonia. The other form is an entirely different process. The patient commences with stooping and rounding of the shoulders, lassitude and fatigue, dulness of the apex, generally the left. There may be no cough at this early stage, the dulness constantly extends downward and then gradually all the familiar symptoms develop. There is no expectoration in the early stages as the bronchi are not affected. There is no acute inflammatory process extending into the lungs, the diseased process is going on in the lung itself and consists of a new growth, which starting in one apex gradually substitutes itself for the normal lung tissue. We have, therefore, two disease processes, differing in everything but their results, viz., cavitation of the lungs, and they must not be treated in the same manner. The difference should be recognized at once on examining the case. The principal perceptible difference appears to be the existence of moist râles between the edge of consolidation and the functionating lung, indicating a positive bronchial pneumonia instead of a tubercular growth of abnormal tissue.

140. **Medico-Sociologic Problems.**—The evils from vices and mistakes in the raising of children are noticed by Kime, who advocates the sterilization of criminals and the prohibition or restriction of marriage of idiots, insane, tuberculous, epileptics, dypsomaniacs and syphilitics, also the raising of the age of consent and the regulation of child labor. These are a few things which he thinks would favorably affect the development of the race; others will be considered later.

143. **Epilepsy.**—Spratling's article considers the subject of epilepsy, particularly its causation, and finds that nearly 85 per cent. of epileptics became so before they reached the age of 20 and that the four factors of heredity—epilepsy, alcoholism, insanity and tuberculosis—in addition to the cerebral palsy cases of early life, produce 67 per cent. of all cases we meet. The time to treat the epileptic, therefore, is while he is young, and the disease but recently developed. As regards surgical work, he thinks much that has been done ought not to have been done. The great principle of doing no harm should be observed in these cases. Before any operation is undertaken to relieve the epilepsy the case should be studied from all sides, taking into account the hereditary factors, character, duration, etc., of the seizures, and especially the mental condition of the patient at the time. If this has been impaired he doubts the propriety of any operation as a means of cure. He does not wish to create the impression that epilepsy is incurable, for some can be cured and fully 75 per cent. of all cases can be greatly benefited.

147. **Tuberculosis and Trades.**—The question as to what business had best be carried on by tuberculous patients is treated of by Ambler, who thinks that tuberculous patients should not have charge of public halls or places where people assemble. He calls attention particularly to clerks and others that handle food stuffs. The butcher, the thinks, generally possesses an immunity, at least that has been his experience, but bakers are particularly susceptible. While the baking of bread may destroy the tubercle bacillus that has gone into the material before, and in this respect diminishes the danger, this is not the case with green vegetables or those that are eaten in the same condition in which they are purchased. Tuberculous individuals, therefore, should not be employed in market places or in stores generally, and yet there are few physicians who can not cite cases where such are employed in just these occupations.

British Medical Journal, September 28.

The Action of Arsenic on the Healthy Tissues of the Skin. Leslie Roberts.—The action of arsenic on the skin is, to some extent, veiled in uncertainty. It is astonishing how readily it can gain access to the body, food, garments, wall paper, etc. In fact whenever chemists wish to test its presence in any body they require previously to satisfy themselves that it is absent in the reagents and all apparatus to be employed. Starting from the scientifically established fact that arsenic possesses like hemoglobin a respiratory property, as shown by Binz and others, we must seek the answer to the question, whether the development of active oxygen within the tissues of the skin is actually the direct cause of morbid changes in these tissues and of the whole train of symptoms which accompany arsenical poisoning? In other words, is the cause dynamic rather than simple and direct and are the extraordinary effects which it produces of a nutritive rather than of an inflammatory order? After these introductory remarks Roberts notes the presence of arsenic in the human tissues and shows that the thyroid gland contains by far the largest proportion. It is also found in very small quantities in the mammary glands, thymus, with traces in the hair, horns, skin, milk and bones, with not a trace to be discovered in the blood or urine, and but a very minute one in the feces. Arsenic is, therefore, with one variable exception found in the areas of quiet oxidation, while all those in rapid oxidation are free from all traces of it. Normal physiologic arsenic is also removed from the body chiefly by keratinized cells of the cu eous epithelium and in very minute quantities by the feces. seems possible that the health of the body, as well as the m tenance of healthy metabolism of the skin, is dependent u the chemical partnership of mercury, iodids, phosphorus, arsenic, largely in the thyroid gland. The effects of arsenic the skin are, 1, pigmentation; 2, hyperkeratinization; 3, quamation; 4, atrophy, and 5, fatty degeneration. The ment is melanin, which appears to be developed within germinal epithelium as the result of arsenical stimulat Hyperkeratinization is the most important sign of arsen poisoning. It involves the strata above the cones and tendency is toward complete arrest of inward growth. Desq mation is another highly characteristic symptom, especially its chronic manifestation. Atrophy and fatty degeneration later phenomena. Gautier infers, and it may be proven sible in the future, that there exist in the body certain fu tional elements. Only a few of these have as yet been covered, but he assumes them to be essential for certain spec functions. Thus manganese is said to be essential to the idizing ferment; iodin to the thyroid; phosphorus to nuclei fluorin to the bone cells. Some of these functional eleme appear to play the principal part, others may be styled subs tution elements; thus arsenic may take the place of ph phorus in relation to nucleins; selenium act for sulphu copper, zinc or manganese may replace iron and so on. I one thing we have to learn, viz., that arsenic is not merely drug possessing curative powers, and that it is not necessar an irritant poison; that it is not a poison in itself, but tl its action is initiated and determined by the tissues the selves; that its effects are essentially of a nutritive or brought about by the agency of active oxygen, and that th effects are beneficent to the organism when the oxidation slow, and injurious when too rapid. The more highly orga ized the cell and unstable its protoplasm and the more ra its metabolic processes, the more rapidly does it feel and ma fest the action of arsenic.

A Note on the Morbid Conditions Simulating Adenoic Wyatt Wingrave.—The conditions that simulate adenoids a according to Wingrave, as follows: 1. Diminutive choanæ a nostrils, which are frequent; usually associated with a l pharyngeal vault and imperfect maxillary development; i mobile velum palati, and a gothic arched palate. The nostr may be uniformly diminutive, or may be normal, while t turbinals are disproportionately large. The former conditi seems to be associated with development of the maxilla whi the turbinal disproportion is especially associated with puber and the balance may not be restored for several years. 2. T low pharyngeal vault which occurs in rickety children, ar often accompanies the former conditions. 3. Paresis of t soft palate and pharyngeal muscles, which may be the resu of any form of nasal obstruction and due to various forms paralysis or neglect, or bad breathing habits. 4. Prominent crest of the vomer or backward prolongation of the nasal septum, which is not rare. This is often associated with other abnormalities. 5. Forward projection of the vertebral column, in which the arch of the atlas is the chief offender, though the second and even the third cervical bodies may often be involved. 6. Retropharyngeal abscess, and here Wingrave calls special attention to the retropharyngeal lymphatic gland, supposed to be only present in early life, and which may be the seat of acute or chronic inflammation, giving rise to swellings that seriously encroach upon the upper passages. 7. Undue prominence of the soft parts covering the internal pterygoid plate and the tuberosity of the palate is not rare, and is associated with general thickening of the mucous membrane. 8. Finally, the postnasal space may be obstructed by webs and neoplasms which can not be described in this communication. These here enumerated include the commonest only of these morbid conditions that simulate or are responsible for the existence and persistence of "adenoid" symptoms.

On the Removal of Tonsils in Adults. H. Lambert Lack.—The removal of tonsils in adults is not such a simple matter as it is in children: 1, on account of the danger of hemorrhage, which is much more common in patients over 15 years of age; and 2, the effect it may have upon the voice. The methods of removal are noticed by Lack, who remarks first on the electric cautery, which is suitable for much enlarged tonsils where removal is not necessitated by recurring tonsillitis and complete removal is undesirable. Tonsillotomy should never be performed in adults with very large tonsils, but in some cases where repeated attacks of tonsillitis occur and the tonsils are too small to be snared, they may be cut away to some extent. Removal with the cautery snare leaves a large charred wound in the throat with increased danger of infection, and is not favorably mentioned. The cold-wire snare is the only method applicable to cases of much enlarged tonsils and seems to have more advantages here than any other method. Enucleation by incision through the mucous membrane between the anterior pillar of the fauces and the anterior border of the tonsils, shelling out the tonsils, is not difficult to perform if care is taken to keep outside the tonsil capsule. General anesthesia, however, is advisable. There is little risk of hemorrhage; the tonsil is completely removed and in some cases of flat tonsil there is no other applicable method. Each case, however, must be judged by itself; there should be no routine method for all.

The Lancet, September 28.

The Diagnosis of Cancer of the Stomach. John C. Hemmeter.—The early diagnosis of cancer of the stomach is rare in the literature; the patients do not usually present themselves in time and decline to be submitted to methods most promising for early diagnosis. Hemmeter says: "The most important information from all the physical signs and symptoms and from the chemical and microscopic investigations may be arranged in the order of their diagnostic value as follows, but I do not desire to be dogmatic in this statement: 1. Chronic gastritis or nervous dyspepsia with progressive aggravation in spite of four weeks' proper treatment. 2. Progressive weakening of the peristaltic power. This can only be confused with the benign stenosis of the pylorus, but in the latter case—the benign stenosis—there is, as a rule, a normal or an excessive amount of hydrochloric acid. In malignant stenosis there is absence of hydrochloric acid and formation of lactic acid. The diagnosis between benign and malignant stenosis may be difficult at the beginning of the clinical observation of any case, but after two to four weeks of observation it should present no difficulties. 3. Progressive diminution in the amount of free hydrochloric acid with steady loss of peristaltic power. 4. The presence of large numbers of atypical and asymmetrical mitoses after gastric curettage, together with characteristic histologic changes in the glands previously described—especially in cases of motor insufficiency. With such clinical indications exploratory laparotomy should be undertaken, and where this step proved the diagnosis to be wrong, in my experience, it was discovered that conditions were present which necessitated operative interference anyway, such as, for instance, motor insufficiency from cicatrices, indurated ulcers, or adhesions. In this schema the diagnostic value of the Oppler-Boas bacilli, tumor, and lactic acid are not referred to because they are late signs. I do not wish to be understood to say, however, that a surgical operation should not be undertaken when these late signs are present. Many times even the presence of a tumor is not a contra-indication to an operation, because a malignant tumor in the stomach may be present, as I have noted on three occasions, and no signs of metastases of infection of the lymph glands were discoverable by a careful search at the necropsy." The diagnosis of carcinoma of the stomach is still in its rudimentary stage. The further development of the subject, the author thinks, does not depend so much upon the bacteriologic investigation as upon the pathologic and physiologic chemistry of the cell.

Syphilitic Affections of the Stomach. W. Soltau Fenwick.—It is thought that while the mouth and rectum commonly suffer from syphilitic lesions the stomach escapes, notwithstanding the evidence to the contrary. Syphilis may affect the stomach in three ways: 1. By the formation of gummata; 2, by producing endoarteritis; 3, by exciting chronic inflammation of the mucosa. Gummata of any size are rarely found. The tumor, which is often multiple, is usually in the submucous tissue of the pyloric region near the lesser curvature. It increases in size and its substance undergoes softening, which usually becomes destroyed and an ulcer is produced which has certain features distinguishing it from the simple variety. It is often irregular, scalloped or triangular. Its edges are thickened and undermined, while its wall and base are shaggy, cheesy, hemorrhagic or covered with firmly-adherent yellow slough. It is usually surrounded by an area of some degree of chronic inflammation and syphilitic manifestations occur in other portions of the abdominal viscera; perforation of the stomach has not been observed in these cases. Obliterative endarteritis affecting the gastric vessels must not be regarded as necessarily an indication of syphilis as it may be observed with chronic simple ulcer and other conditions. The syphilitic variety is rarely a primary complaint, and as far as Fenwick has observed is always associated with gummata in the liver, spleen, pancreas and elsewhere. It chiefly affects the smaller branches of the pyloric vessels and causes inflammatory thickening of the mucous membrane, interstitial hemorrhages and ulcerations. It may produce symptoms of chronic ulceration of the stomach or of dyspepsia followed by hematemesis. Chronic gastritis may be the direct or indirect result of syphilis. The latter is most common, and is due either to embarrassment of the gastric circulation from disease of the liver or spleen or to lardaceous degeneration of the vessels of the stomach, to secondary disease of the kidneys or to the specific cachexia. It does not differ histologically from the usual forms, and like them, usually subsides when the exciting cause has been removed. We should not fall into the mistake of many that every gastric ulcer occurring in syphilitics is due to syphilis. About 5 per cent. of all the population suffer from gastric ulcer from other causes and gastric irritation in a syphilitic subject may possibly be due to injudicious medication. Chronic syphilitic ulcer of the stomach is most common in men between 25 and 40, and in cases where secondary symptoms have been slight or rapidly removed by treatment. Pain is invariably present and nocturnal pain has been considered especially characteristic; this is also true of attacks of emesis during the night, though they may occur with simple ulceration. Anemia is invariably present, and the peculiar sallow complexion of many of the patients is suggestive of specific cachexia. As a rule the complaint fails to respond to ordinary means and may show a tendency to relapse even with anti-syphilitic remedies. Gastritis occurs both in hereditary and acquired syphilis, and is chiefly characterized by its chronicity and intractibility to ordinary treatment. The loss of flesh, anemia and debility are out of all proportion to local symptoms. The mild forms of gastritis occurring in adult life are practically undistinguishable from the alcoholic varieties, but in severe cases the anemia, debility, etc., are suggestive of malignant growths. He has seen a number of cases where cancer has been diagnosed that were relieved by specific treatment, which is a great point of distinction in these cases. The subjects of gastric cancer are very intolerant of mercury and the iodids, which is the reverse with the syphilitic form. The gastric crises of locomotor ataxia occur at irregular intervals and are seldom excited by the ingestion of food. A few days' trial of iodid of potassium will usually clear up any doubt. Rest, of course, and other methods given for ordinary gastric disorders are advisable, but mercury should always be combined with the iodids as the latter are less effective without it. The patient should be warned as to the dangers of a relapse.

Bulletin Medical (Paris), August 17.

Medical Injections of Quinin into the Cerebrospinal Fluid. Jaboulay.—The subarachnoid injection of cocain produces extensive but transient analgesia; when quinin is thus injected, the analgesia is less in extent, but it lasts for two weeks. Jaboulay has found the latter an effective measure for the relief and possibly cure of painful, purulent cystitis; cancers of the rectum; sciatica, arthralgia of the pelvis and hip; neuritis of the leg; pelvic neuralgia; incontinence of urine, and inveterate onanism. He uses the quinin in a concentrated solution, .5 cg. to the cubic centimeter. He has found 5 cg., or even 2.5 cg. sufficient for the curative effect, while this amount is not large enough to cause neuritis or destructive lesions of the cauda equina. He makes the injection in the lumbar subarachnoid space. The analgesia induced includes the genital organs, bladder and rectum. It is accompanied by paresis of the corresponding muscles. With a larger dose it is possible to induce anesthesia of the foot and lower portion of the leg, suggesting that this measure may prove useful in the treatment of Little's disease. He points out that the varying results obtained by various surgeons in spinal cocainization is largely due to the temperature of the solution of cocain. When it is heated to 99.5 F. its diffusion is more rapid. If not warmed, it stays at the bottom of the subarachnoid cavity, and it loses .005 of its density when heated to 104 F. Both cocain and quinin should be used only for medical and not for surgical purposes, as surgical anesthesia can be obtained by simpler measures.

September 4.

Aid to Prognosis of Diphtheria. Rabot.—The subcutaneous injection of saline solution in a child with diphtheria may throw light on the prognosis. If the child voids more urine after it, without vomiting or diarrhea, the diphtheria will run a mild course, no matter how stormy the onset. But, if the amount of urine is not increased, and the little patient vomits or has diarrhea, the prognosis is grave, even in apparently benign cases. The latter phenomena indicate that the toxins have affected the heart fibers, and the organ is thus unable to respond to the action of the saline solution.

Presse Medicale (Paris), September 21.

Some Experimental Experiences with Phototherapy. R. Romme.—Borissoff reports tests with dogs and rabbits which showed that the growth and development was retarded in young animals kept in dark rooms. Even when the largest and strongest animals were transferred to the dark rooms, by the end of the second week their growth was less in proportion than that of the control animals in ordinary light rooms. He compares the stimulus exerted by the light to that of exercise on a muscle. Drigalski found that the electric rays, far from possessing any bactericidal power, predisposed the animal organism to infection, and enhanced its gravity. This fact can not be due to the heat alone, as other animals kept at the same temperature, but not exposed to the electric light, proved much more resistant in all the tests. Strebel has found electric light baths applied as a therapeutic measure, effectual in curing soft chancres, leg ulcers, acne, and, in general, all ulcerating cutaneous lesions; he eliminates the heat rays by passing the light through a vessel containing copper sulphate solution. In rheumatic affections the results were inferior to those obtained by hot air, but the treatment proved more efficacious in arteriosclerosis, in fatty degeneration of the heart, in a few cases of bronchial catarrh, and occasionally in neuralgia. The effect was negative in nephritis.

Curable Gangrene of the Lids. H. Roger.—A robust man with no pathologic antecedents, was suddenly affected with spontaneous gangrene of the lids of one eye. It commenced with a simple patch of inflammatory edema, followed by fever for four days, the entire process developing to complete restitution in twenty-one days. The eye was not involved. Only one similar case could be found in the literature. A large aërobic micrococcus was cultivated from the serum, pathogenic for rabbits and guinea-pigs, but harmless for rats. The micrococci discovered in the lesions of gangrenous mammitis are also aërobic.

Treatment of "Thin Diabetes." P. Maucquaire.—Lancereaux applies the term "diabète maigre" to the glycosuria connected with an affection of the pancreas, in opposition to the "fat diabetes" of arthritic and gouty subjects. The pancreatic juice may be produced in excess in this variety of diabetes, or it may be deficient. Several comparative tests on rabbits are described, which suggest that the sugar produced in the organism by the transformation of starchy food, and the sugar generated in the tissues by autodigestion, pass into the liver. Here, in normal conditions, they are transformed into glycogen and deposited. The liver ferment, whose formation is dependent on the pancreatic zymases and the pancreatic juice itself, dissolves this stored glycogen as needed, and the sugar is transformed in the circulation into water and carbon dioxid. Absence of the pancreatic juice in an affection of the pancreas, entails the absence of the liver ferment. The glycogen in the liver is not dissolved, and the sugar which constantly arrives from the food or autodigestion, finding no room in the liver, continues to circulate in the blood until the kidneys separate it and eliminate it in the urine. The practical conclusions from this hypothesis are that the physician should not hesitate to administer pancreatin in cases of "thin diabetes" in a dosage as high as three to eight grams a day, if necessary.

Painless Application of Sublimate to Mucous Membranes. De Pierris.—The smarting produced by the application of water to the nasal mucous membrane is due to the lack of isotonicity between the molecular concentration of the blood and of the fluid employed. The smarting can be prevented by adding about 9 per cent. of salt, which renders the fluid isotonic with the blood. When this is done, sublimate can also be added, 1 to 10,000, or even 1 to 4000. It does not induce the slightest pain in this isotonic combination with saline solution, but otherwise it does.

Revue de Medecine (Paris), September.

Cerebellar Hereditary Ataxy. A. Thoma.—The Haud family, of Paris, is distinguished by the fact that five members of the family in two generations have presented the same curious ataxy with other cerebellar symptoms. The various cases were carefully studied. The autopsy findings in the case of Amelia, who succumbed last, at the age of 47, show the same anatomic foundation as all the others—a lesion in the cerebellum or cerebellar tracts. The cerebrospinal axis was exceptionally small in every case, but the lesion itself differed in nature and exact site in each. The cerebellum was small, but the spinal cord was still smaller in proportion. Actual degeneration was noted only at a few points, especially and invariably in the cerebellar tracts. Aside from this Haud family, Sanger Brown's is the only other instance known of family hereditary ataxy, and in his case the lesion extended through the cerebellar system in the cord while the involvement of the cerebellum itself was doubtful.

Two Cases of Sciatic Neuritis Caused by Mercurial Injections. Dopter.—After the unfortunate experience indicated in the title, Dopter made a study of the danger zone for these injections. He has established that the course of the sciatic nerve follows a line starting two fingers' breadth outside of the postero-superior iliac spine and terminating in the median axis of the posterior surface of the thigh. The danger zone extends 3 cm. each side of this line, from the sacro-sciatic foramen, where the nerve emerges, to the center of the dividing line of the buttocks below.

Revue Mensuelle des Mal. des Enfants (Paris), September.

Cocain Cause of Idiocy in Offspring. A. B. Marfan.—A healthy couple had two healthy children, when the father became addicted to the use of cocain. For years he was in the habit of taking as much as three grams, a day, exclusively by the nose. Two children have since been born, both typical specimens of microcephalous idiocy.

Revue de Therapeutique (Paris), August 15 and September 1.

Influence of Certain Foods on the Gastric Juice. Potapow-Pracaitis.—In Schiff's experiments on dogs, he found that a marked peptogenic power was possessed by dextrin, bouillon, raw meat, bread, cheese, peptones, gelatin and black coffee. Pawlow found that Liebig's extract, bouillon, water, milk, gelatin and raw meat possess the property of increasing the secretion of gastric juice. In the research described in the present article, it was established that the results obtained by Schiff and Pawlow supplement and confirm each other. Certain substances, such as bouillon and raw meat, are both peptogenic and gastric juice-producing, or succagogue. The influence on the secretion of gastric juice is completely abolished when the substances are administered by the rectum, showing that the direct intervention of the nervous system is required for this sympathetic reflex secretion. On the other hand, the peptogenic effect is fully as marked when the substance is absorbed by the rectum as when absorbed by the stomach. The peptogenic effect is, therefore, transmitted by the intermediation of the blood.

Semaine Medicale (Paris), September 18.

Nodular Tuberculosis of the Prepuce. J. Sabrazès.—A lump the size and shape of an olive developed in the under surface of the prepuce, about 1.5 cm. above its free edge, in a man of 26. It simulated a sebaceous cyst, but it appeared about a year after the patient had noted dull pains in the renal and hypogastric regions and displayed other symptoms of slowly developing tuberculous lesions of the urogenital organs. Koch's bacillus was discovered in the urine, and also in the caseous masses which formed a large portion of the tumor. It was readily excised, and the patient was thus relieved of his most troublesome symptoms, and was able to resume his occupation.

Treatment of Malaria with Iodin. Regnault.—During an attack of malaria assuming the gastro-bilious form and rebellious to quinin, Regnault took a teaspoonful of a mixture of tincture of iodin and potassium iodid, 4 gm. of each, in 100 gm. of water. This was equivalent to 2 cg. of pure iodin, and he found that the chill was arrested in fifteen minutes and the skin resumed its functions. He has administered it to numbers of patients since, and always with the same result, the prompt subsidence of the attack. A second dose is rarely necessary. Quinin has to be taken before the attack; if it fails to prevent it, the iodin treatment is indicated during or, better still, at the commencement of the attack. On account of the incompatibility of iodin and quinin, the two should not be taken together.

Berliner Klin. Wochenschrift, September 2.

Relations Between Human and Bovine Tuberculosis. P. Baumgarten.—Twenty years ago Rokitansky conceived the idea that it might be possible to arrest or even to cure malignant tumors by the antagonistic action of the tubercle bacillus which was an article of belief at that day. He consequently considered himself justified in taking advantage of this possibility in the treatment of otherwise hopelessly doomed patients with inoperable carcinoma or sarcoma. As the tubercle bacilli of human and of bovine tuberculosis were considered identical, the latter were used for the purpose, and more than half a dozen patients were thus inoculated with considerable amounts of bacilli taken from cattle, and which had proved their extreme virulence in tests on rabbits. Most of the patients survived from several months to over a year, but, after the healing of the pustule induced by the injections, none of them exhibited any signs of tuberculosis, and neither macroscopic nor microscopic tuberculous lesions were discovered at any autopsy, although Baumgarten was himself prosector at the time and all passed through his hands. The inoculations had no noticeable effect on the patients, and the attempted treatment was abandoned. In 1893 one of Baumgarten's pupils inoculated two calves with tubercle bacilli, one in the eye with bacilli from the ox, and the other in the eye and flank with bacilli from tuberculous patients. One calf died in six weeks with all the symptoms and anatomic lesions of diffuse miliary tuberculosis, such as is seen in man. The second calf, inoculated with human tuberculosis, remained healthy, and, when killed several months later, no traces of either human or bovine tuberculosis could be discovered. The control rabbit died of generalized tubercular lesions in about five months. Baumgarten adds that he has not been able to find in the literature a single authentic instance of the transmission of human tuberculosis to cattle. He agrees with Koch that practically there is very little danger to man from bovine tuberculosis, but he is convinced of the identity of the bacilli and that external circumstances are responsible for their differences. The classic picture of human miliary tuberculosis was induced in the calf mentioned, and Tangl and Troje have also demonstrated that certain external factors, such as the fumes of iodoform, may modify the pathogenic properties of human tubercle bacilli to such an extent that they induce the bovine form of tuberculosis when inoculated into animals. The histologic identity of both forms is confirmed by the fact that the caseous process so characteristic of human tuberculosis, occurs likewise in the bovine tubercles, only it is frequently disguised by the rapidly succeeding calcification of the caseous masses. This has nothing to do with the essential disease process, and is often observed in the caseous masses in man. The extent of the calcification in animals is probably due to their larger proportion of calcium salts. The variability in the pathogenic properties of bacteria is a familiar fact. It is more than probable that the bacilli have adapted themselves to their habitat in the course of time, and lost their pathogenic properties for others. But until this is definitely established he observes that there should be no relaxation in the prophylactic measures employed, as further research may lead to opposite conclusions.

Treatment After Operation of Diffuse Purulent Peritonitis. T. Gluck.—The principles on which Gluck bases his after-treatment are exemplified in the smooth and rapid recovery of a man who had been gored by an ox. When he recovered consciousness he found his intestines lying between his knees, covered with blood, ditch water, fecal matters, dirt and sawdust, and exposed to the glare of the direct sunlight for hours. Gluck believes that warmth, moisture and the action of light, favor the healing of peritonitis or any intestinal lesion after an operation. After much experimental research on animals, applying the results to man, he constructed an apparatus in which the intestines are eventrated and received in a warm, moist, glass case, which allows the action of electric light and frequent irrigation. Cardiac insufficiency or paralysis frequently follows the reposition of the intestines after a laparotomy; this danger is entirely obviated, as the intestines are not replaced until all danger of shock is past. He mentions Fenton B. Turck's views with especial approval. After the operation the patient is placed on a water mattress on a frame, to which the box for the intestines is fastened. The whole is then placed in an empty bathtub, and Schäfer's warm water regulator is attached. Gluck has thus treated cases of gangrenous hernia, volvulus after perforation of the appendix, and peritoneal tuberculosis, besides the ordinary diffuse purulent peritonitis. His results have been so favorable that he considers this method as a brilliant progress in surgery, although he claims no priority for it, as it is merely the legitimate outcome of the general trend of abdominal surgery, and as the technique is still far from perfect. In certain uncomplicated cases of diffuse peritonitis, a small laparotomy with lavage of the peritoneum may be sufficient, using a 3 per cent. solution of salt and boric acid or of 1 per cent. salicylic acid, and glass drainage or tamponing. The continuous bath is liable to infect the wound. The abdominal wound should not be sutured at all, but should be left wide open. By this etc., are suggestive of malignant growths. He has seen a number of cases where cancer has been diagnosed that were relieved by specific treatment, which is a great point of distinction in these cases. The subjects of gastric cancer are very intolerant of mercury and the iodids, which is the reverse with the syphilitic form. The gastric crises of locomotor ataxia occur at irregular intervals and are seldom excited by the ingestion of food. A few days' trial of iodid of potassium will usually clear up any doubt. Rest, of course, and other methods given for ordinary gastric disorders are advisable, but mercury should always be combined with the iodids as the latter are less effective without it. The patient should be warned as to the dangers of a relapse.

Bulletin Medical (Paris), August 17.

Medical Injections of Quinin into the Cerebrospinal Fluid. Jaboulay.—The subarachnoid injection of cocain produces extensive but transient analgesia; when quinin is thus injected, the analgesia is less in extent, but it lasts for two weeks. Jaboulay has found the latter an effective measure for the relief and possibly cure of painful, purulent cystitis; cancers of the rectum; sciatica, arthralgia of the pelvis and hip; neuritis of the leg; pelvic neuralgia; incontinence of urine, and inveterate onanism. He uses the quinin in a concentrated solution, .5 cg. to the cubic centimeter. He has found 5 cg., or even 2.5 cg. sufficient for the curative effect, *while this amount is not large enough to cause neuritis or destructive lesions of the cauda equina.* He makes the injection in the lumbar subarachnoid space. The analgesia induced includes the genital organs, bladder and rectum. It is accompanied by paresis of the corresponding muscles. With a larger dose it is possible to induce anesthesia of the foot and lower portion of the leg, *suggesting that this measure may prove useful in the treatment of Little's disease.* He points out that the varying results obtained by various surgeons in spinal cocainization is largely due to the temperature of the solution of cocain. When it is heated to 99.5 F. its diffusion is more rapid. If not warmed, it stays at the bottom of the subarachnoid cavity, *and it loses .005 of its density when heated to 104 F. Both cocain and quinin should be used only for medical* and not for surgical purposes, as surgical anesthesia can be obtained by simpler measures.

September 4.

Aid to Prognosis of Diphtheria. Rabot.—The subcutaneous injection of saline solution in a child with diphtheria may throw light on the prognosis. If the child voids more urine after it, without vomiting or diarrhea, the diphtheria will run a mild course, no matter how stormy the onset. But if *the amount of urine is not increased, and the little patient* vomits or has diarrhea, the prognosis is grave, even in apparently benign cases. The latter phenomena indicate that the toxins have affected the heart fibers, and the organ is thus unable to respond to the action of the saline solution.

Presse Medicale (Paris), September 21.

Some Experimental Experiences with Phototherapy. R. Romme.—Borissoff reports tests with dogs and rabbits which showed that the growth and development was retarded in young animals kept in dark rooms. Even when the largest and strongest animals were transferred to the dark rooms, by the end of the second week their growth was less in proportion than that of the control animals in ordinary light rooms. He compares the stimulus exerted by the light to that of exercise on a muscle. Drigalski found that the electric rays, far from possessing any bactericidal power, predisposed the animal organism to infection, and enhanced its gravity. This fact can not be due to the heat alone, as other animals kept at the same temperature, but not exposed to the electric light, proved much more resistant in all the tests. Strebel has found electric light baths applied as a therapeutic measure, effectual in curing soft chancres, leg ulcers, acne, and, in general, all ulcerating cutaneous lesions; he eliminates the heat rays by passing the light through a vessel containing copper sulphate solution. *In rheumatic affections the results were inferior to those obtained by hot air, but the treatment proved more efficacious in arteriosclerosis, in fatty degeneration of the heart, in a few cases of* bronchial catarrh, and occasionally in neuralgia. The effect was negative in nephritis.

Curable Gangrene of the Lids. H. Roger.—A robust man with no pathologic antecedents, was suddenly affected with spontaneous gangrene of the lids of one eye. It commenced with a simple patch of inflammatory edema, followed by fever for four days, the entire process developing to complete restitution in twenty-one days. The eye was not involved. Only one similar case could be found in the literature. A large aërobic micrococcus was cultivated from the serum, pathogenic for rabbits and guinea-pigs, but harmless for rats. *The micrococci discovered in the lesions of gangrenous mammitis are also* aërobic.

Treatment of "Thin Diabetes." P. Maucquaire.—Lancereaux applies the term "diabète maigre" to the glycosuria connected with an affection of the pancreas, in opposition to the "fat diabetes" of arthritic and gouty subjects. The pancreatic juice may be produced in excess in this variety of diabetes, or it may be deficient. Several comparative tests on rabbits are described, which suggest that the sugar produced *in the organism by the transformation of starchy food, and the* sugar generated in the tissues by autodigestion, pass into the liver. Here, in normal conditions, they are transformed into glycogen and deposited. The liver ferment, whose formation is dependent on the pancreatic zymases and the pancreatic juice itself, dissolves this stored glycogen as needed, and the sugar is transformed in the circulation into water and carbon dioxid. *Absence of the pancreatic juice in an affection of the* pancreas, entails the absence of the liver ferment. The glycogen in the liver is not dissolved, and the sugar which constantly arrives from the food or autodigestion, finding no room in the liver, continues to circulate in the blood until the kidneys separate it and eliminate it in the urine. The practical conclusions from this hypothesis are that the physician should *not hesitate to administer pancreatin in cases of "thin diabetes"* in a dosage as high as three to eight grams a day, if necessary.

Painless Application of Sublimate to Mucous Membranes. De Pierris.—The smarting produced by the application of water to the nasal mucous membrane is due to the lack of isotonicity between the molecular concentration of the blood and of the fluid employed. *The smarting can be prevented* by adding about 9 per cent. of salt, which renders the fluid isotonic with the blood. When this is done, sublimate can also be added, 1 to 10,000, or even 1 to 4000. It does not induce the slightest pain in this isotonic combination with saline solution, but otherwise it does.

Revue de Medecine (Paris), September.

Cerebellar Hereditary Ataxy. A. Thoma.—The Haud family, of Paris, is distinguished by the fact that five members *of the family in two generations* have presented the same curious ataxy with other cerebellar symptoms. The various cases were carefully studied. The autopsy findings in the case of Amelia, who succumbed last, at the age of 47, show the same anatomic foundation as all the others—a lesion in the cerebellum or cerebellar tracts. The cerebrospinal axis was exceptionally small in every case, but the lesion itself differed in nature and exact site in each. The cerebellum was small, but the spinal cord was still smaller in proportion. Actual degeneration was noted only at a few points, especially and invariably in the cerebellar tracts. Aside from this Haud family, Sanger Brown's is the only other instance known of *family hereditary ataxy, and in his case the lesion* extended through the cerebellar system in the cord while the *involvement of the cerebellum itself was doubtful.*

Two Cases of Sciatic Neuritis Caused by Mercurial Injections. Dopter.—After the unfortunate experience indicated in the title, Dopter made a study of the danger zone for these injections. He has established that the course of the sciatic nerve follows a line starting two fingers' breadth outside of the postero-superior iliac spine and terminating in the *median axis of the posterior surface of the thigh.* The danger zone extends 3 cm. each side of this line, from the sacro-sciatic foramen, where the nerve emerges, to the center of the dividing line of the buttocks below.

Revue Mensuelle des Mal. des Enfants (Paris), September.

Cocain Cause of Idiocy in Offspring. A. B. Marfan.—A healthy couple had two healthy children, when the father became addicted to the use of cocain. For years he was in the habit of taking as much as three grams a day, exclusively by the nose. Two children have since been born, both typical specimens of microcephalous idiocy.

Revue de Therapeutique (Paris), August 15 and September 1.

Influence of Certain Foods on the Gastric Juice. Potapow-Pracaitis.—In Schiff's experiments on dogs, he found that a marked peptogenic power was possessed by dextrin, bouillon, raw meat, bread, cheese, peptones, gelatin and black coffee. Pawlow found that Liebig's extract, bouillon, water, milk, gelatin and raw meat possess the property of increasing the secretion of gastric juice. In the research described in the present article, it was established that the results obtained by Schiff and Pawlow supplement and confirm each other. Certain substances, such as bouillon and raw meat, are both peptogenic and gastric juice-producing, or succagogue. The influence on the secretion of gastric juice is completely abolished when the substances are administered by the rectum, showing that the direct intervention of the nervous system is required for this sympathetic reflex secretion. On the other hand, the peptogenic effect is fully as marked when the substance is absorbed by the rectum as when absorbed by the stomach. The peptogenic effect is, therefore, transmitted by the intermediation of the blood.

Semaine Medicale (Paris), September 18.

Nodular Tuberculosis of the Prepuce. J. Sabrazès.—A lump the size and shape of an olive developed in the under surface of the prepuce, about 1.5 cm. above its free edge, in a man of 26. It simulated a sebaceous cyst, but it appeared about a year after the patient had noted dull pains in the renal and hypogastric regions and displayed other symptoms of slowly developing tuberculous lesions of the urogenital organs. Koch's bacillus was discovered in the urine, and also in the caseous masses which formed a large portion of the tumor. It was readily excised, and the patient was thus relieved of his most troublesome symptoms, and was able to resume his occupation.

Treatment of Malaria with Iodin. Regnault.—During an attack of malaria assuming the gastro-bilious form and rebellious to quinin, Regnault took a teaspoonful of a mixture of tincture of iodin and potassium iodid, 4 gm. of each, in 100 gm. of water. This was equivalent to 2 cg. of pure iodin, and he found that the chill was arrested in fifteen minutes and the skin resumed its functions. He has administered it to numbers of patients since, and always with the same result, the prompt subsidence of the attack. A second dose is rarely necessary. Quinin has to be taken before the attack; if it fails to prevent it, the iodin treatment is indicated during or, better still, at the commencement of the attack. On account of the incompatibility of iodin and quinin, the two should not be taken together.

Berliner Klin. Wochenschrift, September 2.

Relations Between Human and Bovine Tuberculosis. P. Baumgarten.—Twenty years ago Rokitansky conceived the idea that it might be possible to arrest or even to cure malignant tumors by the antagonistic action of the tubercle bacillus which was an article of belief at that day. He consequently considered himself justified in taking advantage of this possibility in the treatment of otherwise hopelessly doomed patients with inoperable carcinoma or sarcoma. As the tubercle bacilli of human and of bovine tuberculosis were considered identical, the latter were used for the purpose, and more than half a dozen patients were thus inoculated with considerable amounts of bacilli taken from cattle, and which had proved their extreme virulence in tests on rabbits. Most of the patients survived from several months to over a year, but, after the healing of the pustule induced by the injections, none of them exhibited any signs of tuberculosis, and neither macroscopic nor microscopic tuberculous lesions were discovered at any autopsy, although Baumgarten was himself prosector at the time and all passed through his hands. The inoculations had no noticeable effect on the patients, and the attempted treatment was abandoned. In 1893 one of Baumgarten's pupils inoculated two calves with tubercle bacilli, one in the eye with bacilli from the ox, and the other in the eye and flank with bacilli from tuberculous patients. One calf died in six weeks with all the symptoms and anatomic lesions of diffuse miliary tuberculosis, such as is seen in man. The second calf, inoculated with human tuberculosis, remained healthy, and, when killed several months later, no traces of either human or bovine tuberculosis could be discovered. The control rabbit died of generalized tubercular lesions in about five months. Baumgarten adds that he has not been able to find in the literature a single authentic instance of the transmission of human tuberculosis to cattle. He agrees with Koch that practically there is very little danger to man from bovine tuberculosis, but he is convinced of the identity of the bacilli and that external circumstances are responsible for their differences. The classic picture of human miliary tuberculosis was induced in the calf mentioned, and Tangl and Troje have also demonstrated that certain external factors, such as the fumes of iodoform, may modify the pathogenic properties of human tubercle bacilli to such an extent that they induce the bovine form of tuberculosis when inoculated into animals. The histologic identity of both forms is confirmed by the fact that the caseous process so characteristic of human tuberculosis, occurs likewise in the bovine tubercles, only it is frequently disguised by the rapidly succeeding calcification of the caseous masses. This has nothing to do with the essential disease process, and is often observed in the caseous masses in man. The extent of the calcification in animals is probably due to their larger proportion of calcium salts. The variability in the pathogenic properties of bacteria is a familiar fact. It is more than probable that the bacilli have adapted themselves to their habitat in the course of time, and lost their pathogenic properties for others. But until this is definitely established he observes that there should be no relaxation in the prophylactic measures employed, as further research may lead to opposite conclusions.

Treatment After Operation of Diffuse Purulent Peritonitis. T. Gluck.—The principles on which Gluck bases his after-treatment are exemplified in the smooth and rapid recovery of a man who had been gored by an ox. When he recovered consciousness he found his intestines lying between his knees, covered with blood, ditch water, fecal matters, dirt and sawdust, and exposed to the glare of the direct sunlight for hours. Gluck believes that warmth, moisture and the action of light, favor the healing of peritonitis or any intestinal lesion after an operation. After much experimental research on animals, applying the results to man, he constructed an apparatus in which the intestines are eventrated and received in a warm, moist, glass case, which allows the action of electric light and frequent irrigation. Cardiac insufficiency or paralysis frequently follows the reposition of the intestines after a laparotomy; this danger is entirely obviated, as the intestines are not replaced until all danger of shock is past. He mentions Fenton B. Turck's views with especial approval. After the operation the patient is placed on a water mattress on a frame, to which the box for the intestines is fastened. The whole is then placed in an empty bathtub, and Schäfer's warm water regulator is attached. Gluck has thus treated cases of gangrenous hernia, volvulus after perforation of the appendix, and peritoneal tuberculosis, besides the ordinary diffuse purulent peritonitis. His results have been so favorable that he considers this method as a brilliant progress in surgery, although he claims no priority for it, as it is merely the legitimate outcome of the general trend of abdominal surgery, and as the technique is still far from perfect. In certain uncomplicated cases of diffuse peritonitis, a small laparotomy with lavage of the peritoneum may be sufficient, using a 3 per cent. solution of salt and boric acid or of 1 per cent. salicylic acid, and glass drainage or tamponing. The continuous bath is liable to infect the wound. The abdominal wound should not be sutured at all, but should be left wide open. By this means the peritoneum can be thoroughly cleansed and the organism relieved of the task of resorbing, eliminating and overcoming the infection. *Restitutio ad integrum* becomes possible, especially in case of tuberculous processes. Gluck uses the apparatus alone or in combination with a loose tampon over which is drawn a gauze bag. When the strings of the bag are drawn up like those of a tobacco pouch, the enclosed intestines are protected. Another method is to pass long silk threads through the fascia and muscles of the wound and tie them, after loosely piling up a mound of gauze in the wound, over which the threads are tied. The box for the intestines might be modified so as to be used even during the operation.

Balancing Extension. F. CRAMER.—The foot of the patient is attached to a weight suspended from a pulley at the head of the bed. The rope passes over the pulley on a frame above; under a pulley fastened to his ankle; over a second pulley above, and finally under a second pulley on the tip of the foot; it then fastens to a hook in the frame above close to the foot of the bed. The rope above the patient's leg thus outlines a W. Another weight is suspended from a pulley at the foot of the bed, not far above the plane on which he lies, and this rope is attached to his heel. The limb is thus in continual extension, but at the same time considerable movement is possible.

Centralblatt f. Innere Medizin (Leipsic), August 24.

Leucocytosis in an Outbreak of Sweat. W. HAMES.—The leucocytes increased by 3000 and 5000, and in some cases to double the previous amount in all the children examined, except those in cachexia, fifteen minutes after either natural or induced sweating. Half an hour after the children were wiped, dressed and transferred to a freshly made bed, the leucocytes had returned to the normal number. About twenty-nine children were tested and the results confirm the function of positive chemotaxis exerted by the hydrotics, and antipyretics in febrile conditions, as well as by the spontaneous or induced sweats in both health and disease.

September 7.

Gymnastics on the Sickbed. H. ZEEHUISEN.—During convalescence from infectious disease, and in conditions requiring rest in bed, great benefit may be derived from systematic gymnastics under the physician's instructions. Convalescence is shortened, and recovery is more complete than without these gymnastics. As a typical example is described the case of an elderly woman, with fatty degeneration, arrythmia and edema of the legs. Medical treatment and rest had not alleviated any of the symptoms. Zeehuisen instituted a series of gymnastic movements as she lay in bed; each were performed but once, and with first one leg and then the other, three for the thigh and one for the knee. At first the movements were passive, then active and then against slight resistance, always in the morning. After two weeks each movement was repeated twice. The success of these measures in the course of two months was remarkable. Pulse, respiration and skin were normal; after a course of treatment at Bad Nauheim the patient has been completely cured for years and to date. These bed exercises are especially beneficial for bedridden obese patients, in certain gynecologic affections, in gout and particularly in traumatic neuroses.

Dermatologische Centralblatt (Berlin), September.

The Bottini Operation for Hypertrophied Prostate. C. STERN.—With chronic, complete retention and a hard prostate, the Bottini operation with Freudenberg's modification of Bottini's original galvanocautery, is a more effective procedure than any other known to date. All it claims to accomplish is to make an opening in the dam which is holding back the urine. It is safer than continual catheterization in the hands of the ordinary patient, but as in the case of a colleague who catheterized himself with ease and absolute asepsis, circumstances may render it superfluous. It should be reserved for cases which are persistently rebellious to ordinary measures.

Deutsche Med. Wochenschrift (Leipsic), September 26.

Treatment of Dysentery with Calomel. A. PLEHN.—The method of treating dysentery by small doses of calomel, inaugurated by Plehn, has abundantly proved its efficacy in his experience during the last three years at Cameroon, and also in South America, where it has been introduced. He orders first two tablespoonfuls of castor oil, which clears up the diagnosis and cleanses the intestines. The next morning he gives a tablet of 3 cg. of calomel every hour for twelve hours, continuing this treatment the next and the following day, suspending it at night. After each tablet the patient must rinse his mouth thoroughly with a solution of tincture of krameria or of salicylic acid. After three days of the calomel he substitutes a tablet of .5 gm. of bismuth every hour for twelve hours, continues this for three days and then reduces the amount to 6 gm. a day, until all pathologic symptoms have vanished, when he continues with 3 gm. a day for a time longer. A number of cases are described in detail showing the efficacy of this method of treatment. The calomel probably acts as a disinfectant. The germs causing the dysentery develop throughout the large intestine, but it is the products of their metabolism which cause the pain, the increased secretion, the disturbance in the intestinal resorption and the intense irritation of the intestinal walls. Under the action of these chemical toxins the mucous lining is destroyed, ulcerative processes develop and secondary infection is liable to occur, frequently due to the amoebæ. Calomel given continuousl as described, kills the germs and the production of their toxi is arrested. The acute irritation of the intact mucous mem brane rapidly subsides. If the ulcerations are already in prog ress, they may require some time to heal, but healing is pro moted by a strictly fluid diet and the bismuth. Certain live affections subsequent to slight intestinal infections, may lik wise be due to the toxins secreted, as they rapidly recove under this calomel treatment of the primary intestinal infe tion. He is inclined to believe that the same treatment migh prove effective in early cases of typhoid fever and in choler but he has had no opportunity to test it in these diseases. H recommends others to try six or eight doses of calomel ever two hours in mild cases of dysentery.

A Case of Tuberculosis of the Knee Benefited by Koch' New Tuberculin. BRUNZLOW.—The patient was a lad of 1 who had suffered from a tubercular affection of the knee sinc 1897. After surgical treatment of the joint, the condition became aggravated, and the general condition grew rapidl worse. He was then treated with tuberculin (T. R.), com mencing with 1/1000 mg., and the beneficial effect was rapidl apparent, as the lad gained four and one-half pounds in th first week. He was treated with four separate courses o tuberculin, in two years, gradually increasing the dose fron .0005 mg. to 2 mg. each time, carefully avoiding reaction an waiting until every trace of induced elevation of temperatur had vanished before injecting the tuberculin again. The bene fit was apparent in the rapid increase in weight and th disappearance of all local symptoms. At present, the joint i normally movable and free from pain, but the muscles are a little weaker than in the other knee, and a faint grating sound can be heard on movement. There is still a slight reaction to a test-injection of old tuberculin, and consequently the case is not a cure. However, the results show such improvement in every respect, with constant gain in weight, that they should encourage others to try tuberculin as a therapeutic measure in rebellious cases of surgical tuberculosis.

Treatment of Exudates. E. HOMBERGER.—The fluids of the body always seek to maintain an osmotic balance. If we assume that the blood and an exudate or transudate have the same osmotic tension, dilution of the blood will be followed by the passage of the excess of water into the exudate, reducing the osmotic tension of the latter, while the concentration of the blood increases in proportion. As the blood becomes more concentrated, the exudate is reabsorbed under the action of the same laws of osmosis. Homberger states that by utilizing these principles we have an effective means at our disposal of promoting reabsorption of exudates and transudates. The blood can be diluted by the administration of water. It is absorbed more readily if taken in small amounts in an empty stomach, and most rapidly of all, when the water is slightly acid and weak in salts. Nature demands water in infectious fevers and lemonade not only relieves the thirst, but has a directly curative influence on the disease by promoting osmosis. The benefit of saline infusion is directly due to the water. In diabetes, the sugar in the blood causes absorption of water from the tissues, in Nature's attempt to restore the balance of osmotic pressure. The overfilled vascular system empties the excess of water into the kidneys, while Nature calls for more water to supply the demand, thus explaining the polyuria and thirst in diabetes. Homberger concludes by stating his belief that in therapeutics the internal use of water is as important as its external use, and that it can be harmful only in exceptional cases. Simmonds announced last year that in none of the autopsies which he has conducted was he able to detect any indications that the infusion of saline solution had been responsible for dilatation of the right ventricle. The great objection, that a weak heart is not able to stand it, is thus shown to be unfounded.

Lamp for Photography on a New Principle. Sophus Bang.—All the lamps hitherto used for phototherapy were originally constructed for optical purposes. None of them aimed to produce a cold light, rich in ultra-violet rays. Bang announces that he has devised a lamp in which the materials were selected for their properties in the spectrum. He finds iron most suitable for the electrodes, instead of carbon tips, and keeps it cool by a circulation of water inside. The iron tips do not generate rays, and the light is actually an arc light, as the rays are generated in the space between the tips. Its bactericidal power is sixty times greater than that of the ordinary arc light. Its effect on the skin is likewise much more intense. Five minutes' exposure at a distance of one yard will induce a severe erythema of several days' duration. For local treatment, he has designed a small lamp, which, with the compressor, is not much larger than an ordinary tablespoon. The whole is placed directly on the skin, as there is so little heat that a distance of 1 to 1.5 cm. is ample. With 5 amperes and 40 volts, it is possible to obtain in five minutes as strong a reaction over 10 sq. c., as has hitherto been obtained with an apparatus of 60 amperes and 50 volts in one and one-quarter hours. As the light is so powerful, neither concentration nor automatic regulation is required, and it can thus be very cheaply constructed.

Three Cases of Pure Hereditary Ataxia. E. Weber.—A family is described in which three children present the typical clinical picture of Friedreich's disease. The parents are healthy and well-to-do, and have two other healthy children. The affection commenced about the sixth year in each, and can be observed in the three patients in the incipient, established and advanced stages. The youngest is 7, and the oldest 18 and bedridden. The ataxia in his case is more pronounced than Weber has ever witnessed in any tabetic subject.

Value of Colchicin in Gout. K. Kuester.—Since restricting himself to a more vegetable diet and avoiding meat, Kuester has found that he suffers less with gout, to which he is naturally and hereditarily predisposed. An occasional attack still occurs, and he finds relief in colchicin alone. He takes it in pills, 5 cg. colchicin to 1.5 gm. each of licorice extract and powder, to make 20 pills. Two of these will frequently abort a mild attack, and four pills in the course of two days reduce the symptoms very materially and shorten the course of the attack. Thus, after reclining for one day, he is soon able to attend to his practice, and is agile again in eight to ten days, with all the gouty deposits absorbed. Without the colchicin, he has to recline for two weeks and is stiff and aching for three weeks longer. His personal experience has been confirmed by that of gouty patients for whom he has prescribed the colchicin.

Treatment of Meniere's Symptom-Complex. G. Heermann.—Certain symptoms in this affection can be traced to the ears, others to the nerves, and others to a general cause. In order to differentiate and apply appropriate treatment, Heermann has been appealing to his colleagues to report their experiences. He sends a blank circular on demand and gratefully receives all communications addressed to him at Kiel. During the acute attacks he states that a position in which the vertigo is attenuated can almost always be found, but the patient is unable to find it for himself. He must be made to recline, with the upper part of the body slightly raised and the head turned toward the sound side. Both the nausea and the vertigo become much attenuated when the correct position is found. The bromids are the only internal remedies of any value. In case of syphilitic antecedents specific treatment is indicated. If there is a history of a preceding chronic, suppurating otitis media, the semi-circular canal must be opened up, and a cholesteatoma is sometimes found. The Ménière symptoms may appear during the course of a dry catarrh of the middle ear. Besides the usual treatment of this condition, Heermann advocates pilocarpin. He commences with one-tenth of a Pravaz syringeful of a 2 per cent. solution, increasing by one-tenth daily until copious sweating is induced; usually less than seven-tenths are required. The patient must stay in bed while sweating. The pilocarpin banishes the vertigo, and frequently improves the hearing, but is contraindicated in case of elderly or corpulent persons. In apoplectiform deafness it has worked wonders in his experience. He also found thyroid treatment beneficial in two cases with goiter. The patient may have forgotten his old ear affection when the Ménière symptoms appear. The vertigo in such a case is liable to be attributed to the stomach. There is frequently pronounced stagnation in the vascular system and constipation. Appropriate local treatment and out-of-door exercise may improve the hearing with the general health, and the vertigo vanishes. He describes several instructive examples. One patient, for instance, with bilateral chronic catarrh of the middle ear, exhibited the Ménière symptoms and deafness during and after a pregnancy. Treatment of the ear and twenty-one injections of pilocarpin, with exercise, resulted in the cure of all the symptoms including the deafness. They all returned during another pregnancy, but yielded as before. When the Ménière symptoms develop on a neuropathic basis, operation on the ear is liable to be distinctly injurious. It is in these cases that quinin, electricity and similar measures score their triumphs. Quinin should be completely avoided by the aurist, as well as the salicylates, as they expose the functions of a diseased ear to the most serious dangers.

To Test the Permeability of the Nose. F. Bruck.—The Journal described Glatzel's mirror, in the issue for September 28, p. 874. Bruck points out that it tests the permeability of the nose during expiration only, while it affords no information in regard to inspiration. The latter may be hindered by a floating polyp, sucking in of the nostrils or other impediment affecting inspiration alone.

Therapeutische Monatshefte (Berlin), August.

Treatment of Scrofulosis and Tuberculosis by Inunctions of Cod-Liver Oil. B. Rohden.—For five years Rohden has been using a mixture of 50 per cent. deodorized cod-liver oil, balsam of Peru, and oil of cinnamon, lemon and thyme, combined with lanolin, glycerin and an alkali, to rub into the skin of scrofulous and tuberculous children. He reports extremely satisfactory results from this inunction with "dermosapol," as he calls the mixture. It is a stable, aromatic preparation, of which every particle is absorbed. It is rubbed into the chest and back in the morning, and into the abdomen, buttocks and limbs at night. About 100 gm. are required for ten or twelve days. The cells and tissues are influenced by the cod-liver oil and the lymph becomes saturated with the ethereal oils and the balsam. Tuberculosis on a scrofulous basis is exceptionally benefited by this treatment, especially glandular and joint affections and lupous lesions.

Artificial Respiration in Treatment of Bronchitis. Heermann.—An apparently moribund, six-months' infant in progressing bronchitis was saved by artificial respiration, including Schultze's swinging and pressure on the false ribs, maintained for two hours. Since then Heermann has ordered artifical respiration in every severe case of bronchitis in a child. The nurse or the parents are instructed to apply slight pressure with one hand on the false ribs during expiration, changing the hand frequently. Expectoration is promoted, respiration deepened, the rapid breathing becomes slower and the pulse stronger. The expulsion of accumulated secretions is promoted by this measure, and the threatening paralysis of the muscles of respiration averted. The procedure is repeated several times a day for half an hour at a time.

Suturing the Tissues Without Foreign Material. F. Schultze.—The conditions of success with the method of suturing which Schultze has been using with great satisfaction for two years, are complete hemostasis, and normal elasticity of the skin. The lips of the wound are coaptated and a row of Roser's torsion forceps is applied .5 to 1 cm. apart to hold the lips together. Cotton-collodion dressings are then applied in the interspaces. As soon as the collodion is dry, the forceps are removed, and a protecting bandage applied over the whole.

September.

Dietetic Treatment of Pregnancy. Prochownik.—Delivery can be almost certainly much facilitated in women with a small conjugata vera, not less than 8 cm. in diameter, by restricting the fluids to 500 c.c. a day, with 130 to 160 albumin, 80 to 130 fats and 100 carbohydrates, the total averaging 1800 to 2000 calories. Prochownik has now a record of 17 personal cases, and 31 collected in the literature, with a total of 62 births, all the children being alive at the date of publication. The previous births had been extremely difficult and tedious, and many of the children had died. On the above diet for the last ten or twelve weeks all the deliveries were much easier. With a conjugata of less than 8 cm. artificial premature delivery is the only resource and the precautionary diet is unnecessary. In women with normal pelves, but debilitated from any cause, congenital chlorosis, hemorrhages, etc., he commences dieting treatment early in the pregnancy, with repose in bed or reclining out of doors, for several weeks, better away from the home environment. The patients are encouraged to take as much albumin, fats, cream and fluids as possible, with frictions, gentle massage and small amounts of iron. To develop the lacteal secretion in women whose mothers and grandmothers had been unable to nurse their children, he orders a diet rich in carbohydrates, with massage of breasts, and reports 7 cases in detail, showing benefit in 2. He also tabulates 5 cases of obesity in which he forbade soups, sweets, etc., and ordered exercise, massage of the entire body, except the stomach, and restricted the fluids to 500 or 600 c.c., with 120 to 130 gm. bread and other food to taste, but not in large amounts nor much at a time. He commences this dieting treatment of pregnant women with a tendency to obesity, as early as possible. He pleads for a more general study of this subject. The possibility of its efficacy is now demonstrated beyond question. It only remains to work out the details. He states that women in tropical climates, with their vegetable and fruit diet, usually bear children more easily than the women of the north, although the pelvis averages smaller in tropical races.

Wiener Med. Wochenschrift, August 31.

Serum Treatment of Erysipelas. V. Jez.—The serum is derived from the same patient on whom it is used. It always induces a reaction, evidenced by a rise of temperature after one or two hours, and rapid improvement of all the symptoms. The number of leucocytes in the blood increases while the toxic substances are eliminated in the urine, as shown by its increased toxicity. No after-effects were noted in the ten cases in which Jez tried this serum treatment. If 5 to 10 gm. are not enough to induce the reaction, he increases the amount. The serum is taken from a blister artificially produced for the purpose.

Epilepsy Cured by an Intercurrent Disease. M. Turnowsky.—The three cases related all occurred under Turnowsky's personal observation, continued for many years. The first was a man of 38, who had from fifteen to twenty seizures on some days, the epilepsy dating from his seventeenth year, until 1887, when it was completely cured by an attack of croupous pneumonia. The second was a woman of 34, with five or six seizures during the month, between the age of 20 and 25. At this time she contracted pneumonia, and has had no seizure since. The third patient was a boy of 12, who used to have ten to fifteen seizures a day between the age of 2 and 6. At the latter age he contracted scarlet fever, and since then has been completely cured of his epilepsy. The cure in these cases has persisted respectively fourteen, ten and six years. He concludes with the suggestion that it would not be such a great risk to send an epileptic to a locality where pneumonia was endemic, or to expose an epileptic child to scarlet fever, as these cases, carefully observed, in addition to those on record in the literature, would fully establish the possibility of the disappearance of epilepsy after an intercurrent infectious disease.

Janus (Amsterdam), September.

Progress in the History of Medicine. H. F. A. Peypers.—"The universities in France and Germany are now discussing measures to give the history of medicine a larger place in the curriculum. In America many of the principal medical schools have a chair for the instruction of history of medicine. Dr. Sarah Hackett Stevenson, who is professor of obstetrics, ethics and the history of medicine at the Woman's Medical School, at Chicago, interests us particularly, as the combination of ethics with the history of medicine is such an excellent idea. This association is as rare in medical curricula up to the present time, as the presence of a woman in the faculty." Havana has a professor for the history of medicine and another for the history of pharmacy. From Australia comes an important work by Dr. W. J. Stewart McKay, entitled "History of Gynecology Among the Ancients." It seems remarkable to receive a serious work on the history of medicine from such a remote point as Sydney, so far from the universities and reference libraries of the old world.

Extragenital Endemics of Syphilis in Hungary. E. Weyner.—Three of these endemics are on record; one was traced to a drinking cup used by the children of a school in which one of the teachers was syphilitic. In both the others, the infection occurred by arm to arm vaccination. In the latest endemic, 270 persons were infected by this means.

Gazzetta Degli Ospedali (Milan), September 22.

Koch's Views of Tuberculosis. E. Maragliano.—The destructive action of the gastric juice and the auto-sterilization of the intestines recently promulgated by Kohlbruegge, explain the rarity of tuberculosis of the intestines from food infected by the tubercle bacillus, as well as from the bacilli in the sputa swallowed by tuberculous patients. This argument has therefore little value as cited by Koch to sustain his theory of the non-transmissibility of bovine tuberculosis to man. Maragliano has established that killed cultures of human tubercle bacilli cause intense toxic phenomena in cows and goats, showing that these animals are susceptible to the toxins of human tuberculosis, and, therefore, necessarily to its bacilli. Michelazzi has recently published the results of study of the prolonged use of sterilized milk from tuberculous cows. He demonstrates that the milk from a tuberculous animal, even if the teats are intact, and no bacilli pass into the milk, is yet extremely injurious, as the serum of the milk is toxic, even more toxic than that of the blood. The amount of toxin in the milk varies with the severity of the tuberculous process, but its toxic properties are unaltered, and are not affected by sterilizing the milk by heat. A chronic intoxication of the organism ingesting the milk is determined in time. His experiments at Pisa indicate that the profound marasmus accompanying tuberculosis in man and animals, is the result of the action of the toxins resulting from the presence of the tubercle bacilli, thus confirming Maragliano's assertions that tuberculosis is preeminently a toxicosis.

Serotherapy of Whooping Cough. T. Silvestri.—About 120 c.c. of blood were drawn from the arms of two children recovering from whooping cough. It was mixed with equal parts of saline solution and shaken up with 1 per cent. of chloroform and set aside to settle for twenty-four hours. It was then filtered and from 15 to 22 c.c. were injected into five other children with whooping cough. In two very severe cases the injection was repeated after five days. The effect of the serum treatment was evident at once. The general symptoms rapidly vanished and the cougn and broncho-pneumonic phenomena also subsided completely in from eight to eleven days.

Giornale Delle Accad. di Med. di Torino, July.

Severe Hemorrhage from the Ear. G. Gradenigo.—Rohrer has recently related a case of severe hemorrhage from the ear, due to varices or bluish dilatations of the veins on both tympanic membranes. In Gradenigo's case the hemorrhage occurred during a paracentesis of the membrane on suspicion of acute otitis from the symptoms observed. There was no inflammation, but the incision opened an angiomatous tumor, with threatening arterial hemorrhage. The tumor was located just inside the membrane and may have been an aneurysmal dilatation of some abnormally diverging artery, but was more probably an angiomatous tumor with extensive dilatation of the vessels.

Hot Baths in Pneumonia. A. Bormans.—When the fever goes above 39.5 C. (103 F.), Bormans places the patient in a bath tub of water at 40 C. (104 F.), first applying an ice-cap to his head and cooling the face with ice. As soon as the patient is immersed, water is added to raise the temperature of the bath to 44 C. (111 F.) and the temperature is maintained at this point for fifteen minutes, when the patient is returned to bed. The effect is extremely beneficial; the relief is almost immediate. The patient sweats profusely and his agitated delirium is quieted. In 12 cases thus treated, the crisis occurred on the fourth day in 3, the fifth day in 1, the sixth day in 4, the seventh day in 3, and the eighth day in 1. One patient died the eighth day with cerebrospinal meningitis. The afflux of blood to the periphery relieves the circulation in the lungs and the sweat eliminates a large proportion of the toxins. These hot baths are contra-indicated, of course, in case of heart disease or arteriosclerosis, but in all other conditions the benefit derived should cause them to be generally adopted. Bose recommends hot baths in all the acute infectious diseases of children, but Giappone was the first to advocate baths of this temperature. Ortner reports excellent results from them in his "Manual of Therapeutics," published at Vienna last year. He orders them in bronchitis and pneumonia. The blood pressure usually drops slightly during the bath, but rises later, and surpasses what it was before the bath. The temperature may rise a fraction of a degree, and the pulse is slightly increased. In a few cases the blood pressure remained slightly below what it was before the baths, but the patient's euphoria and sweat were pronounced in every case.

New Patents.

Patents of Interest to Physicians, issued September 17 and 24:

683,012. Optical instrument. Henry H. Hill, St. Louis, Mo.
682,936. Hernial truss. George V. House, Mount Vernon, N. Y.
682,854. Stopper for water-bags. Charles E. Longden, Hampden, Conn.
682,832. Speculum. J. Gordon McPherson, Toronto, Canada.
682,638. Eye-tester. Henry D. Reese, Abbeville, S. C.
682,650. Bed-pan. George Thornton, F. D. Freeborn and W. Hi[illegible]
[illegible] ppository. Henry H. Foringer, Eria, Pa.
[illegible] Arthur E. Bonesteel, Central City, Colo.
[illegible] appliance. Patrick F. Cassidy, Boston, Mass.
683,044. Bed-pan. Richard E. Holder, Columbus, Ind.
683,216. Therapeutic battery. Joseph A. Minturn, Indianapolis, Ind.
683,192. Apparatus for assisting the hearing. Alfred F. Watch. Philadelphia, Pa.

Books Received

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review. as dictated by their merits, or in the interests of our readers.

Dictionary of Philosophy and Psychology, Including Many of the Principal Conceptions of Ethics, Logic, Anesthetics, Philosophy of Religion, Mental Pathology, Anthropology, Biology, Neurology, *Physiology*, Economics, Political and Social Philosophy, Philology, Physical Science, and Education, and Giving a Terminology in English, French, German and Italian. Written by Many Hands and Edited by James Mark *Baldwin, Ph.D. (Princeton)*, Hon. D.Sc. (Oxon.), Hon. LL.D. (Glasgow), Stuart Professor in Princeton University. With the Co-operation and Assistance of an International Board of Consulting Editors. In Three Volumes, with Illustrations and Extensive Bibliographies. Vol. I. Cloth. Pp. 644. Price, $5.00. New York: The MacMillan Co. 1901.

The American Illustrated Medical Dictionary. For Practitioners and Students. A Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry and Kindred Branches, Including Much Collateral Information of an Encyclopedic Character, Together with New and Elaborate Tables of Arteries, Muscles, Nerves, Veins, etc.; of Bacilli, Bacteria, Micrococci, Streptococci; Eponymic Tables, Diseases, Operations, Signs and Symptoms, Stains, Tests, Methods of Treatment, etc. By W. A. Newman Dorland, A.M., M.D., editor of the "American Pocket Medical Dictionary." Second Edition, Revised. Leather. Pp. 770. Price, $4.50 net. Philadelphia and London: W. B. Saunders & Co. 1901.

Progressive Medicine. A Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. Assisted by H. R. M. Landis, M.D., Assistant Physician to the Out-Patient *Medical Department of* the Jefferson Medical College Hospital. Volume III. September, 1901. Diseases of the Thorax and Its Viscera, Including the Heart, Lungs, and Blood Vessels—Dermatol[illegible] of the Nervous System—Obstetrics. [illegible] per annum, in four volumes, $10.00. [illegible]: Lea Brothers & Co. 1901.

An International System of Electro-Therapeutics. For Students, General Practitioners, and Specialists. By Numerous Associated Authors. Edited by Horatio R. Bigelow, M.D., Permanent Member of the American Medical Association. Second Edition. Revised and brought up to date, with several New Departments, Embodying the Most Recent Developments of the Science. Edited by G. Betton Massey, M.D., Ex-President and Fellow of the American Electro-Therapeutic Association. Thoroughly Illustrated. Royal Octavo. Pp. x-1147. Price, $6.00. Philadelphia: F. A. Davis Company. 1901.

Pathological Technique. A Practical Manual for Workers in Pathological Histology and Bacteriology, Including Directions for the Performance of Autopsies and for Clinical Diagnosis by Laboratory Methods. By Frank B. Mallory, A.M., M.D., Assistant Professor of Pathology, Harvard University Medical School; and James H. Wright, A.M., M.D., Instructor in Pathology, Harvard University Medical School. Second Edition, Revised and Enlarged. With 137 Illustrations. Cloth. Pp. 432. Price, $3.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

A Treatise on the Acute, Infectious Exanthemata. Including Variola, Rubeola, Scarlatina, Rubella, Varicella, and Vaccinia, with especial reference to Diagnosis and Treatment. By William Thomas Corlett, M.D., L.R.C.P. Lond. Professor of Dermatology and Syphilology in Western Reserve University. Illustrated by 12 Colored Plates, 28 Half-tone Plates from Life, and 2 Engravings. Pages viii-392. Sold only by Subscription. Price, Extra Cloth, $4.00 net, Delivered. Philadelphia: F. A. Davis Company. 1901.

Manual of Chemistry. A Guide to Lectures and Laboratory Work for Beginners in Chemistry. A Text-Book Specially Adapted for Students of Medicine, Pharmacy, and Dentistry. By W. Simon, Ph.D., M.D., Professor of Chemistry in the College of Physicians and Surgeons of Baltimore. Seventh Edition, Thoroughly Revised. With 66 Illustrations, 1 Colored Spectra Plate, and 8 Colored Plates, Representing 64 Chemical Reactions. Cloth. Pp. 613. Price, $3.00. Philadelphia and New York: Lea Brothers & Co. 1901.

Nervous and Mental Diseases. By Archibald Church, M.D., Professor of Nervous and Mental Diseases, and Head of Neurological Department, Northwestern University Medical School, and Frederick Peterson, M.D., Chief of Clinic, Department of Nervous and Mental *Diseases, and Clinical Lecturer on Psychiatry, Columbia* University. Third Edition, Revised and Enlarged. Cloth. Pp. 870. Price, $5.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

Human Physiology. Prepared with Special Reference to Students of Medicine. By Joseph Howard Raymond, A.M., M.D., Professor of Physiology and Hygiene in the Long Island College Hospital, *New York City. Second Edition*, Entirely Rewritten and Greatly Enlarged. 443 Illustrations, 12 of them in Colors, and 4 Full-page Lithographic Plates. Cloth. Pp. 668. Price, $3.50 net. Philadelphia and London: W. B. Saunders & Co. 1901.

International Directory of Laryngologists and Otologists. Containing Names *and Addresses* of Practitioners Engaged in the Study and Practice of Laryngology and Otology. Compiled by Richard Lake, F.R.C.S., Eng. Published under the Auspices of the Journal of Laryngology, Rhinology and Otology. Second Edition, Revised and Enlarged. Leather. Pp. 124. Price, $1.25. London: Rebman, Ltd. 1901.

Electricity in Medicine and Surgery, Including the X-Ray. By William Harvey King, M.D., Editor of the Journal of Electrotherapeutics. In Two Parts. With a Section *on Electro-physiology*, by W. Y. Cowl, M.D., Berlin, Germany, and a Section on the Bottini Operation, by Albert Freudenberg, M.D., Berlin, Germany. Cloth. Pp. 296. Price, $3.50. New York: Boericke & Runyon Co. 1901.

Dose-Book and Manual of Prescription-Writing: With a List of the Official Drugs and Preparations, and the More Important Newer Remedies. By E. Q. *Thornton, M.D., Ph.G.*, *Demonstrator* of Therapeutics, Jefferson Medical College, Philadelphia. Second Edition, Revised and Enlarged. Leather. Pp. 362. Price, $2.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

Transactions of the American Electro-Therapeutic Association. Complete account of Ninth Annual Meeting held at Washington, D. C., September 19, 20 and 21, 1899; also Tenth Annual [illegible] York City, September 25, 26, and 27, 1900. [illegible]-391. Price, Extra Cloth, $2.00 net, De[illegible] F. A. Davis Company. 1901.

A Practical Treatise on Diseases of the Skin. By John V. Shoemaker, M.D., LL.D., Professor of Skin and Venereal Diseases in the Medico-Chirurgical College and Hospital of Philadelphia.

Fourth Edition, Revised and Enlarged with Chromogravure Plates and Other Illustrations. Cloth. Pp. 892. Price, $5.00. New York: D. Appleton & Co. 1901.

A Manual of the Practice of Medicine. By George Roe Lockwood, M.D., Professor of Practice in Woman's Medical College of New York Infirmary. Second Edition, Revised and Enlarged. With 79 Illustrations and 20 Full-page Plates. Cloth. Pp. 847. Price, $4.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

A Text-Book of Obstetrics. By Barton Cooke Hirst, M.D., Professor of Obstetrics in the University of Pennsylvania. Third Edition, Thoroughly Revised and Enlarged. With 704 illustrations, many of them in Colors. Cloth. Pp. 873. Price, $5.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

A Laboratory Course in Bacteriology. For the Use of Medical, Agricultural, and Industrial Students. By Frederick P. Gorham, A.M., Professor of Biology, Brown University. With 97 Illustrations. 12mo. Volume. Cloth. Pp. 198. Price, $1.25 net. Philadelphia and London: W. B. Saunders & Co. 1901.

The Principles of Hygiene: A Practical Manual for Students, Physicians, and Health Officers. By D. H. Bergey, A.M., M.D., First Assistant, Laboratory of Hygiene, University of Pennsylvania. Illustrated. Cloth. Pp. 495. Price, $3.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

Modern Obstetrics: General and Operative. W. A. Newman Dorland, A.M., M.D., Assistant Demonstrator of Obstetrics, University of Pennsylvania. Second Edition, Rewritten and Enlarged. Cloth. Pp. 797. Price, $4.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

A Text-Book of Embryology. By John C. Heisler, M.D., Professor of Anatomy in the Medico-Chirurgical College, Philadelphia. Second Edition, Thoroughly Revised. Illustrated. Cloth. Pp. 405. Price, $2.50. Philadelphia and London: W. B. Saunders & Co. 1901.

A Text-Book of Bacteriology. By George M. Sternberg, M.D., LL.D., Surgeon-General, U. S. Army. Illustrated by Heliotype and Chromo-lithographic Plates and 200 Engravings. Second Edition, Revised. Cloth. Pp. 707. Price, $5.00. New York: Wm. Wood & Co. 1901.

A Text-Book of Diseases of Women. By Charles B. Penrose, M.D., Ph.D., formerly Professor of Gynecology in the University of Pennsylvania. Fourth Edition, Revised. Cloth. Pp. 539. Price, $3.75 net. Philadelphia and London: W. B. Saunders & Co. 1901.

A Manual of Bacteriology. By Herbert U. Williams, M.D., Professor of Pathology and Bacteriology in the Medical Department of the University of Buffalo. With 89 Illustrations. Cloth. Pp. 290. Price, $1.50 net. Philadelphia: P. Blakiston's Son & Co. 1901.

Libertinism and Marriage. By Dr. Louis Julien (Paris), Surgeon of Saint-Lazare Prison. Translated by R. B. Douglas. Pages v-169. Extra Cloth, $1.00 net, Delivered. Philadelphia: F. A. Davis Company, Publishers. 1901.

Twentieth Annual Report of the State Board of Health of New York. For the Year ending December 31, 1899. Transmitted to the Legislature February 15, 1900. Cloth. Pp. 555. Albany: James B. Lyon. 1901.

Transactions of the Medical Association of the State of Alabama. The State Board of Health, Organized 1847—Meeting of 1901. Selma, April 16-19. Cloth. Pp. 508. Montgomery, Ala.: Brown Printing Co. 1901.

The Pathology and Treatment of Sexual Impotence. By Victor G. Vecki, M.D. Third Edition, Revised and Enlarged. 12mo. Cloth. Pp. 329. Price, $2.00. Philadelphia and London: W. B. Saunders & Co. 1901.

Transactions of the Massachusetts Medico-Legal Society. Volume III—Number 3: 1901. Paper. Pp. 44. Boston: Published by the Society. 1901.

Proceedings of the New York Pathological Society. April, 1901. Paper. Pp. 44. Published by the Society.

Maps Accompanying State Board of Health of New York. Twentieth Annual Report for the Year 1899.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Sept. 26 to Oct. 2, 1901, inclusive:

Joseph L. Bell, contract surgeon, from Fort Morgan, Ala., to his home, Richmond, Ind., for annulment of contract.

Henry D. Belt, contract surgeon, leave of absence granted.

James Carroll, contract surgeon, former orders amended so as to direct him to return from Havana, Cuba, to his proper station in Washington, D. C., not later than Nov. 1, 1901.

Max F. Clausius, contract surgeon, on his arrival at Fort Douglas, Utah, to proceed to Fort Grant, Ariz., for post duty; but this order was revoked, and he was directed to proceed to his home, Burrington, Ill., for annulment of contract.

Marshall M. Cloud, lieutenant and asst.-surgeon, U. S. A., sick leave of absence extended.

Frederick A. Dale, lieutenant and asst.-surgeon, U. S. A., to proceed to San Francisco, Cal., for return transportation to Manila, P. I., in compliance with orders from the Division of the Philippines.

Robert C. F[illegible] from Fort Freemont, S. C., to Augusta, Ga., [illegible]tract.

Samuel A. [illegible]rgeon, from duty at Fort Clark, Tex., to his home, Cleburn, Tex., for annulment of contract.

Eugene H. Hartnet, lieutenant and asst.-surgeon, U. S. A., member of examining boards at Governor's Island, N. Y., Sept. 27 and 28.

T. G. Holmes, contract surgeon, leave of absence granted on the expiration of which he will proceed to San Francisco, Cal., for duty on the transport *Grant*.

Frederick E. Jenkins, contract surgeon, on his arrival at Fort Riley, Kan, with troops, will proceed to Fort Morgan, Ala., for post duty.

William P. Kendall, major and surgeon, U. S. A., member of a board at Buffalo, N. Y., to determine the physical fitness of certain persons for appointment as lieutenants in the Army.

William C. LeCompte, contract surgeon, member of a board at Buffalo, N. Y., to determine the physical fitness of certain persons for appointment as lieutenants in the army.

Frederick H. Morhart, captain and asst.-surgeon, Vols., honorably discharged from the service on account of disability.

Edward L. Munson, captain and asst.-surgeon, U. S. A., member of a board at Buffalo, N. Y., to determine the physical fitness of certain persons for appointment as lieutenants in the Army.

Paul Shillock, major and surgeon, U. S. A., now at San Francisco, Cal., to proceed to Fort Riley, Kan., for duty at that post.

J. Samuel White, contract surgeon, having arrived at Seattle, Wash., will proceed to Fort Assinniboine, Mont., for post duty.

Navy Changes.

Changes in the Medical Corps of the Navy, week ending Oct. 5, 1901:

Surgeon P. Leach, ordered to recruiting duty at Port Royal, S. C.

Surgeon P. Leach, order to recruiting duty at Port Royal, S. C., revoked.

Asst.-Surgeon E. J. Grow, order to proceed home, upon detachment from the *Castine*, modified; ordered to the New York Navy Yard.

Medical Director J. C. Ayers, detached from the Naval Hospital, Chelsea, Mass., October 15, and ordered home and to wait orders.

Medical Director D. Dickinson, detached from duty on medical examining board at Washington, D. C., October 10, and ordered to duty in charge of the Naval Hospital, Chelsea, Mass., October 13.

Surgeon S. H. Griffith, detached from duty at the Pan-American Exposition, Buffalo, N. Y., October 9, and ordered to duty as a member of the medical examining board, Washington, October 10.

Surgeon H. L. Law, retired, ordered to duty at Buffalo, N. Y., in charge of the exhibit of the Bureau of Medicine and Surgery, at the Pan-American Exposition, and as attending medical officer at the naval recruiting rendezvous, October 9.

Asst.-Surgeon D. B. Kerr, detached from the *Culgoa*, when put out of commission, and ordered home and to wait orders.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Sept. 28, 1901:

SMALLPOX—UNITED STATES.

California: San Francisco, Sept. 14-21, 1 case.
Indiana: Michigan City, Sept. 24-Oct. 1, 4 cases.
Kentucky, Lexington, Sept. 21-28, 1 case.
Massachusetts: Boston, Sept. 21-28, 2 cases, 1 death.
Michigan: Detroit, Sept. 22-29, 1 case.
Nebraska: Omaha, Sept. 14-21, 1 case.
New Jersey: Newark, Sept. 21-28, 6 cases, 5 deaths.
New York: Sept. 21-28, Elmira, 4 cases; New York, 5 cases, 2 deaths.
Pennsylvania: Philadelphia, Sept. 21-28, 29 cases, 3 deaths.
Ohio: Youngstown, Sept. 21-28, 1 case.
Utah: Salt Lake City, Sept. 14-28, 2 cases.
Washington: Tacoma, Sept. 15-22, 1 case.

SMALLPOX—INSULAR.

Philippine Islands: Manila, Aug. 3-10, 1 case.

SMALLPOX—FOREIGN.

Austria: Budapest, Sept. 2-9, 2 cases.
Belgium: Antwerp, Sept. 7-14, 1 case, 1 death.
Brazil: Pernambuco, Aug. 8-15, 56 deaths; Rio de Janeiro, Aug. 4-18, 114 deaths.
Colombia: Panama, Sept. 16-23, 15 cases.
Great Britain: London, Aug. 24-Sept. 7, 166 cases, 15 deaths.
Italy: Naples, Sept. 7-14, 57 cases, 6 deaths.
Russia: Moscow, Sept. 7-14, 2 cases, 1 death.
Spain: Madrid, June 17-July 15, 6 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, Aug. 3-10, 6 cases, 3 deaths.

PLAGUE—FOREIGN.

Australia: Brisbane, June 1-30, 3 deaths.
Brazil: Rio de Janeiro, Aug. 4-18, 5 deaths.
China: Canton, Aug. 5, diminishing.
Italy: Naples, Sept. 7-30, 15 cases, 4 deaths.

YELLOW FEVER.

Brazil: Pernambuco, Aug. 8-15, 1 death; Rio de Janeiro, Aug. 4-18, 2 deaths.
Cuba: Havana, Sept. 4-21, 3 cases, 2 deaths; Santiago, Sept. 20, 6 cases, 1 death.
Mexico: Vera Cruz, Sept. 14-21, 5 cases, 2 deaths.

CHOLERA.

Java: Batavia, Aug. 3-17, 5 cases, 3 deaths.

Original Articles.

REMOVAL OF FOREIGN BODIES FROM THE AIR PASSAGES.*

DE FOREST WILLARD, M.D.
PHILADELPHIA.

The entrance of a foreign body into the larynx is at once the signal for violent expulsive efforts, and in the majority of instances voluntary extrusion is accomplished. Should the object, however, pass the vocal cords, the route to the bifurcation of the trachea is free and unobstructed. At the bifurcation, as the right bronchus is larger and turns at a less abrupt angle to reach the root of the lung, the body is more likely to fall into its lumen, although this result is by no means positive.† If the object is of irregular shape it will not closely fit, and violent efforts at coughing may still loosen it. It may, however, be arrested in its reverse course at the vocal cords. The violence of the efforts, and the interference with the air supply, unfortunately make inspiratory suction as sudden and nearly as intense as expiration, and the offending object may be sucked further into the air passages. The position of final fixation will depend upon these efforts and upon the size and character of the foreign body. The degree of air hunger will depend upon the amount of blockade. Should the entire main bronchus be obstructed, one-half the respiratory tract will be shut off and the dyspnea becomes extreme. Unfortunately, the physician is rarely at hand and immediate professional measures of relief can not be instituted. The majority of these accidents occur in children; consequently, it is well to instruct parents as to the procedures that should be adopted. The rule as ordinarily taught is to the effect that inversion of the child is unsafe, since the object may become blocked within the larynx. As the body has, however, entered by this route, and as it is the one that must be taken in any voluntary expulsion, it is probably the safest domestic practice that can be instituted and may prevent the object from being sucked still lower in the bronchus. An exaggerated prone Trendelenburg position may be maintained until the arrival of the surgeon. Succussion of the individual and vomiting have occasionally dislodged the body. Coughing should be encouraged, but the violence of inspiratory movements should be restricted as far as possible. Brodie reports the case of an adult in whom a half sovereign had reached the bifurcation of the trachea. By inversion of his body in the prone position, and succussion, he was able, after six weeks, to dislodge the offender by coughing, and full recovery ensued.

If the arrest has taken place at the vocal cords, a laryngoscopic examination will probably reveal it, and it may be extracted by forceps or by laryngotomy. In splitting the thyroid cartilage and opening the larynx, care should be taken to keep directly in the median line and to avoid injury of the arytenoid cartilages and muscles. Cocain should be applied to the mucous membrane both before and during the operation, to prevent reflex inhibitory influences upon the heart.

If an *x*-ray apparatus is at hand, and the foreign body is one which is impenetrable to these rays, as coins, nails, etc., the location may sometimes be accurately determined by making shadowgraphs at different angles. Unfortunately, the distress is so urgent and extreme that it is difficult to induce the child to remain quiet long enough to obtain such a shadow unless ether is administered; still, the *x*-ray representation fills a most important place in both acute and chronic blockades of the air passages.

With children, beads, beans, portions of whistles and toys are common intruders.[1] Hard bodies will probably imbed themselves and do not offer much opportunity of being seized by forceps. Vegetable substances are likely to swell from the moisture if they remain long *in situ*, and are, therefore, difficult to dislodge. In one of my fatal cases one-half of the brown shell of a chestnut was drawn far down into the subdivision of a bronchus.

It is important that the history should be reliable, and when a body has been swallowed, close investigation is necessary to determine whether the object has entered the air passages, and secondly, its location. Of course, there are many cases where the symptoms are unmistakable, but when in doubt a most careful diagnosis should be made. A young child not infrequently has a foreign body in its mouth; is seized with violent coughing as the body attempts to enter the larynx, and yet it passes into the stomach. Not a few tracheotomies have been performed in the search for such objects which have later been passed per rectum; consequently, it is unwise to operate in the absence of definite symptoms. Moreover, many a child has been apparently choked with a toy which was supposed to have been swallowed and which has ultimately been found in the corner of the nursery. I have myself witnessed in the practice of one of our most prominent surgeons, a tracheotomy with prolonged search, in which case the article which had supposedly been swallowed was later found in the pocket of the child, and an examination of the lungs (which should have been made previous to the operation, but which was instituted afterwards) developed the fact that the dyspneic symptoms were due to double pneumonia from ordinary causes.

Following impaction, the pain and the absence of respiratory movements will usually be found upon one side of the chest. The absence of vesicular murmur shows the interference to entrance of air, which will be followed later by dulness and signs of consolidation. In partial occlusion the respiration will be stridulous. The interpretation of these signs, taken in connection with other symptoms, must rest with the surgeon, but he must not be deceived by the lull in symptoms that not infrequently follows the initial blockade.

[1] Poulet: Foreign Bodies, 1880, vol. ii, p. 22.

Tracheotomy.—The opening of the trachea is naturally the most frequent method for reaching an impacted foreign body, an operation that was advocated as early as 1644 by Frederic Manavius. Speedy relief is usually demanded, and ether or chloroform may be employed, or better, local anesthesia in order to retain the use of the extraordinary muscles of respiration. In doing this operation it is better to remove a considerable circle, excising one or two cartilaginous rings, since a simple slit may interfere with the expulsion of the body. If a slit only is made, lateral stitches holding it open are better than a tube. Not infrequently the foreign body is ejected by the primary cough induced by the operation; consequently it should be the duty of an assistant to watch carefully for its appearance. Fortunately, expulsion occurs in about one-half the cases operated upon. This result may be hastened by irritation with a feather. The opening should be as nearly as possible to the top of the sternum, and the forceps must be used with extreme care. The difficulties in locating the body with tracheotomy forceps depend largely upon its character. A bean or kernel is of the same consistency and feeling as the cartilaginous bifurcation of the trachea. If the object is known to be a soft vegetable one, ordinary serrated forceps will not hold. Very short needle-like teeth which will sink into and hold the substance are better. With beads, buttons, tin whistles, etc., successful removal becomes difficult, even when they can be grasped.

One familiar with the use of the cystoscope may, by throwing the head far back and to one side, obtain a view of the foreign body through an inserted tube with electric light. For hard objects a large soft-rubber tube attached to a Bigelow litholapaxy evacuator may be carried down the trachea, and strong suction made upon it, or an aspirating pump or rubber ball may be attached. The evacuator is better, however, lest the body once extracted be again sucked back into position. In case of tacks, nails, etc., a small magnet or an electrical probe may be inserted through the trachea. Blunt curettes, wire hooks, scoops, loops, etc., are occasionally useful. The dangers to the trachea and bronchi by prolonged instrumentation are very great and should never be continued more than a few minutes. The risks of pneumonia are so greatly increased by instrumentation that Weist,[2] in an analysis of 1674 cases, found that the dangers of death from this cause in unsuccessful cases fully counterbalanced the benefits obtained by the number of extractions by tracheotomy. The proportions are one death in three and one-half cases without operation; one in four with tracheotomy. His conclusions in regard to this subject will probably not be materially changed by our present methods, since, although the pneumonia is septic in its origin, yet the sepsis even in former cases was probably not due in large measure simply to the instruments, but to the traumatism to the bronchi. Experiments show that the entering air is septic in the larger bronchi, but aseptic in the smaller divisions.

Failing to secure the intruding object through the tracheal opening, the surgeon is compelled to face two problems, either of which means serious risk to life. Shall he abandon the case to the expulsive efforts of Nature? Shall he rely upon the fact that many such offending bodies have been coughed out even after many years of suffering, and even when the diagnosis of tuberculosis of the lung has seemed positive? In determining the question the surgeon will consider both the character of the foreign body and the amount of interference that it is giving to the air supply. In the case of seeds, etc., voluntary expulsion with subsequent recovery occurs in nearly 74 per cent. of cases.

The other alternative is to reach the bronchus by a direct route. Should the surgeon decide to invade the chest wall in an heroic effort to reach the bronchi, he has before him a series of manipulations, perils, and difficulties that will put to the extreme test his skill, coolness and judgment. Before the introduction of the artificial respiration apparatus, the profound and deadly collapse that immediately followed any invasion of a healthy chest, was sufficient to deter most operators from undertaking such a course. Quenu lost twelve out of fifteen dogs, and while my own experiments have not been quite so serious, they have been very discouraging. In these animals and in rabbits and goats, the communication between the two pleural cavities which exists just above the tendinous center of the diaphragm renders the entrance of air doubly dangerous. Fortunately, we are now better equipped and can confidently rely upon our artificial respiration methods, but without such accessories the conditions are appalling. The exceptional cases in which atelectasis does not occur are so few in number and are so unexplainable that they can not be depended upon. The surgeon must also consider the fact that even when the bronchus is reached by any route, the rigid walls prevent the easy recognition of the foreign body either by sight or touch. Again, as in Curtis' case, even when found in a secondary bronchus, it could not be reached or extracted. In experiments upon dogs I have repeatedly failed to find in the bronchi, pebbles that I had introduced through tracheotomy wounds.

Unfortunately, practice upon the cadaver yields but a slight realization of the conditions found in the living subject. I have at autopsy seen the bronchus of a dog apparently within easy reach, which same bronchus I had seen ten minutes before surrounded by huge pulmonary and azygos veins, with aorta, pneumogastric nerve, root of lung, and every structure in the neighborhood being violently dragged by the wide excursions of the lung in the frightful air hunger of the collapse from acute pneumothorax.

When an opening of any considerable size is made in the pleura and air rushes in, the sudden symptoms of collapse are usually instantaneous. The sudden shifting of the oxygenation of air upon one-half the ordinary circuit; the violent efforts of both inspiration and expiration; the enormous movement of the lung in the effort to produce a vacuum in the chest; the flapping of the pleura and mediastinum; the huge swelling veins filling and emptying and covering the area of operation; the great peril of the patient; the cyanosis and deficient oxygenation are such complications as will greatly delay and often entirely prevent all safe manipulative measures.

I have called attention to these difficulties, not to exaggerate them, nor to deter any surgeon from invading the chest wall, but only to warn him against rash work without proper apparatus, since failure will necessarily bring discredit upon the surgeon and disaster to the individual. A somewhat extended but still incomplete examination of the literature on the subject fails to reveal a recovery after opening of the bronchus. My object is only to urge that unless an artificial respiration apparatus is at hand, and oxygen obtainable, it will be wiser to cease one's operative methods, after short manipulations through a large tracheal opening. With full appliances, however, and a full knowledge of the dangers, one may calmly proceed to enter the chest by a selected route. The conditions are entirely different from those encountered in a diseased lung or pleura, and preliminary injection of air or liquid will avail but little. A small dose of atropia will be helpful.

---

[2] Trans. Amer. Surg. Assoc., vol. i, 1883, p. 121.

The oft-tried expedient of plugging the hole in the pleura, or of dragging the lung into the opening, or grasping the base of the lung, is here of no avail, since the search for the bronchus is absolutely prevented by any of these procedures. Air hunger being then the most serious of the complications, some reliable means of artificial respiration must be at hand, or the patient must die in a few moments. Fortunately, the Fell-O'Dwyer[3] apparatus gives us the much-needed help. The apparatus consists of intubation tubes of various sizes attached to a handle, by means of which one of them of proper size can be held permanently within the chink of the glottis, while air is pumped directly into the lungs by bellows worked by hand or foot pressure. Insufflation is accomplished by moderate pressure about fifteen times in the minute, while expiration is accomplished by the resiliency of the chest walls

Matas has improved upon this apparatus by using a double pneumatic pump, by means of which the exact amount of air introduced can be measured. He has also attached a manometer to regulate the degree of pressure, and has added a branch tube through which anesthetization can be kept up. The entering air is also filtered through a cylinder filled with cotton. The pump can also be employed for forcible aspiration of air from the lung. Bloom, Doyen and others have altered these instruments, but the principle of forcibly supplying air is the same.

After tracheotomy the intubation tip can be introduced through the opening so as to fit the trachea, or it can be carried into the glottis and the wound closed.

A pressure equal to 6 mm. mercury has been found sufficient to dilate the lung, while too great pressure, as 33 mm., will interfere with respiration. If too great force is used, emphysema or air vesicle rupture may take place. The artificial movements should correspond as closely as possible to the normal respirations.

By the employment of such an appliance for carrying on respiration, the chest wall may be opened either anteriorly, posteriorly, or at the side. A large opening while much more dangerous as regards atelectasis, yet greatly facilitates the operation. The employment of a tiny electric bulb within the chest also adds greatly to the rapidity and safety of the manipulations.

Anterior Thoracotomy.—Milton, of Cairo,[4] has recommended an operation of entrance which he calls the normal thoracic invasion, and has successfully practiced it upon a living patient. In young children with flexible bones it would be feasible for reaching the bronchus.

With a saw he splits the sternum longitudinally throughout its entire length, and forcibly retracts the halves, thus separating the two pleural layers, and reaching the anterior mediastinum. In attempting this operation it should be remembered that the pleuræ come together not in the median line, but at a line nearly at the left border of the sternum. In this, as in all other routes of entrance to the thorax, it is absolutely essential that an efficient artificial respiration apparatus shall be constantly employed in the prevention of collapse.

Gaston's[5] anterior opening is made as follows: A quadrilateral trap-door flap is made to include the third, fourth, fifth and sixth ribs, and turned back upon its base at the costal cartilages, thus avoiding the internal mammary. The outer end of the square flap is at the mid-axillary line, and the entire chest walls are cut through with knife and saw.

In making an anterior thoracotomy[6] I have tried various forms of incision. The bronchus of the second lobe can be readily reached anteriorly, can be incised and afterwards stitched with a staphylorraphy needle. In another operation upon the right side, with excision of the fifth rib, I was easily able to expose the bronchus or the right upper lobe. The bronchial, pulmonary and a very high azygos vein were pushed aside and the bronchus incised for a third of an inch without wounding any other structure. Whenever the wound in the bronchus was not subsequently stitched, and the chest wall was closed at the end of the operation, each inspiratory act caused an increase of the pneumothorax by entrance of air through this slit, as was evidenced by the bulging of the wound and the increased dyspnea, ending in death.

The same thing occurred in another dog after an excision of the fifth rib, and an opening of the right bronchus. The pneumothorax steadily increased after the closure of the wound, with bulging and escape of air from within outward at each respiration until death occurred. It is easily seen that while air can pass from the interior of the bronchus outwardly, the rounded shape of the tube prevents return from pleural cavity to bronchus. This air from the large bronchi is septic.

Posterior Thoracotomy.—Nesiloff, Bryant and others have proposed to reach the root of the lung posteriorly. Bryant's operation is as follows:[7] In order to give room for the flap, the scapula is carried far outward by raising the arm and carrying the shoulder forward. A square flap three inches in size is made, with its base toward the spinal column, and three ribs, the third, fourth and fifth, are sawed through as far out as their angles, near the posterior border of the axilla. The pleura is then separated from the anterior surface of the ribs by the fingers, and the flap is turned backward upon its base as a hinge, the ribs being separately turned out. The intercostal arteries were ligated before opening the pleura. The presence of the vena azygos and the pulmonary vein will greatly interfere with manipulations, and these, as well as the pneumogastric, must be carefully avoided. If the foreign body can be located, a long incision (long enough to permit removal without laceration) is made in the bronchus. The bronchus is not closed, but packed and drained, as there will be discharge of mucus and inflammatory products. The flap with the ribs should be replaced, but the middle rib may be removed entirely for drainage, if advisable. Any given spinous process indicates the situation of the vertebral extremity of the rib immediately below. Bryant places the division line between the posterior mediastinum proper and the posterior part of the superior mediastinum at the lower portion of the fourth dorsal vertebra. The separation of the pleura is accomplished with the finger, and also by a sawing motion of a strong silk thread carried beneath the rib. The same ligature may be used to draw beneath the rib a chain saw, so as to operate from within outward and avoid premature wounding of the pleura. This opening is probably more favorable for reaching the esophagus than the bronchus. The bronchus in a man will be distant about one and one-half inches from the opening. The operation is one requiring careful manipulation, cool judgment, speedy recognition and skilful treatment of each danger as quickly as it arises.

[7] Bryant: Posterior Mediastinum. Trans. Amer. Surg. Assoc., vol. xiii, p. 443.

Curtis,[8] in a posterior thoracotomy for an impacted seed vessel of a plant in the right bronchus, tried to extract it with a forceps through the trachea, but failed. At a second operation the boy was placed face downward, with one shoulder raised. A quadrangular flap was raised from the posterior portion of the chest and turned outwardly toward the scapula. Its free edge was near the vertebral spine. The fourth, fifth and sixth ribs were then stripped. The lower layer of the periosteum and intercostal muscles were divided without opening the pleura. The ribs being lifted up, the pleura was carefully detached from the posterior mediastinum and from the posterior chest wall. The bronchus was easily reached, but the azygos vein covering it prevented incision. He encountered the same difficulties that I have always experienced, the violent action of the lung and of the flapping pleura, which interfered most seriously with all manipulations, and he was finally obliged to pack the wound and suspend his efforts. The next day he renewed the attack. The pleura had now become adherent to the lung, and the action was less violent. The bronchus was opened through its posterior wall without hemorrhage, but search with forceps failed to find the body; neither could it be found in the trachea. It was finally discovered by the fingers through the lung substance. The pleura was sewed to the lung and the lung held by a silk stitch. The thermocautery was used directly through the lung substance, but failed to reach the object. The operation was finally suspended on account of the patient's collapse. A drainage tube was inserted with packing, but pneumonia developed on the following day and the patient died in forty-eight hours. At the autopsy the foreign body was found in the secondary bronchus near the end of the drainage tube. The object had been swallowed three days before the first operation. Rushmore[9] in a similar attempt anteriorly was compelled to abandon the operation, and the patient died.

Anyone interested in the subject of intralaryngeal insufflation will be abundantly repaid by perusing Matas' able articles.[10] In these papers he shows that insufflation through a deliberately introduced laryngeal tube was in common practice for the resuscitation of the drowned as far back as the War of the Revolution; that William Hunter used both bellows and intralaryngeal tubes; that Matas' present pump was forestalled by the double pump of Courtois attached to a tracheotomy canula, more than a century ago; that in the earliest years of the last century such a tube was a part of the regular obstetrical outfit for the resuscitation of new-born infants;[11] that Ribemont in 1877 used an intubation canula almost precisely like the one of O'Dwyer; that Truehead of Texas again in 1869 brought out an instrument upon the same plan as the Fell-O'Dwyer instrument.

The Bloom modification of attaching an ordinary rubber syringe bulb to the laryngeal tube is excellent, and the Doyen[12] double bellows and tubes are also good.

The work of Tuffier[13] and Hallion, Quenu and Longuet, Matas, Parham and others, has added greatly to the practical application of artificial forcible insufflation through an intralaryngeal tube. It is now the best known assistant, not only in the performance of lung surgery, but also in the resuscitation of the asphyxiated, the drowned and the new-born. It is also most serviceable in opium poisoning, and in the arrested respiration of anesthetization. (I always keep the Fell-O'Dwyer apparatus alongside the oxygen jar, close outside my clinic door.)

When the foreign body remains permanently fixed in the bronchus, septic pneumonia is a frequent result. In many cases this process leads on to septic abscess, or, if the blockade is complete, gangrene may result. Expulsion of the foreign body and of the purulent surrounding material sometimes occurs, often after months of delay. More frequently, however, death ensues. In the chronic cases the hemorrhage, emaciation and septic conditions often simulate tuberculosis. The proper treatment for all such abscesses or gangrenous areas of lung is a surgical one. The diseased area having been carefully located, a rib should be excised subperiosteally, and contamination of the pleural cavity prevented by suturing of the lung to the chest wall in the form of a parallelogram, before opening. A sharply curved perineal needle with handle is convenient for this purpose. Incision of the abscess and free drainage will offer the best hope for cure.

CONCLUSIONS.

1. Coughing should be encouraged; forcible inspiration restrained.
2. Inversion in the prone position as a domestic practice is advisable.
3. Laryngoscopy is helpful if the body is lodged at the vocal cords. It may be extracted by forceps or by laryngotomy.
4. If time permits, the *x*-ray may be brought into serviceable use for diagnosis.
5. Careful diagnostic investigation is important to determine the actual presence of an impacted body, and its location.
6. Tracheotomy under local anesthesia should be the rule if the object is lodged at the bifurcation or in the bronchi. Tracheoscopy, suction and forceps' manipulation must be cautiously employed. Prolonged instrumentation adds greatly to the danger of pneumonia.
7. If extraction is not secured through the tracheotomy wound the chest wall should not be invaded unless an artificial respiratory apparatus like the Fell-O'Dwyer is at hand, and oxygen available. With the assistance of these appliances, however, the bronchus may be reached, anteriorly or posteriorly, since, by their use, rhythmical movements can be maintained.
8. Resultant abscess of the lung should be treated by incision and drainage.

THE TREATMENT OF EMPYEMA.*

JAMES H. DUNN, M.D.
PROFESSOR OF SURGERY IN THE UNIVERSITY OF MINNESOTA.
MINNEAPOLIS, MINN.

The average treatment of empyema is still far from satisfactory and decidedly behind the present state of surgical science. Tardy diagnosis, inefficient drainage and slovenly after-treatment are the most frequent causes of failure, retarded convalescence and great deformity, results which, though much less frequent than formerly, are not seldom encountered at this late day. The operative treatment of the disease is too often undertaken by those unfamiliar with modern surgical methods. It is high time that a greater respect for the chest should be impressed upon practitioners who appear to regard the treatment of pleural suppurations lightly, and as a fair field for any one able to insert a tube and diligently use a syringe.

The rational treatment of suppurating pleurisies is simple and well known to competent surgeons. Early diagnosis, prompt and efficient drainage, and aseptic after-treatment summarize the whole matter. It is only in the details of technique that discussion is likely to arise and further improvement in methods is to be sought.

EARLY DIAGNOSIS.

Prompt recognition and adequate drainage of the purulent effusion minimizes ruptures into bronchi, systemic infection, loss of lung expansion and pleural thickening. The degree to which the collapsed lung recovers itself depends largely upon the density of the visceral pleura and upon the length of time during which the lung has been compressed. Pulmonic sclerosis and pleural thickening are the chief causes of difficulty in obliterating these cavities. Hence, while there are other causes of tardy or imperfect lung expansion, late diagnosis is one of the most serious and frequent, and one which very moderate skill and diligence ought to almost wholly remove. Perhaps the most excusable delay occurs in certain empyemas developing with or closely following pneumonia, but the abnormal course of events should sufficiently arouse the attendant's suspicions to lead to the use of the exploring needle before many days have passed, even in the most deceptive cases. In any case of thoracic dulness open to doubt, so safe, certain and easy a means of diagnosis as aseptic needling should not long be delayed.

Having early recognized the presence of a suppurating pleurisy, by the needle, a bacterial diagnosis of the variety of the infection is exceedingly desirable. However, pleural suppurations are in practice so generally due to mixed or virulent infections, that serious errors in treatment are not likely to follow its omission in the hands of experienced clinicians to whom the physical properties of the exudate are ordinarily sufficiently characteristic for practical purposes.

EFFICIENT DRAINAGE.

A pleural suppuration being recognized, all the world has agreed that it should be removed; but how and where, have been much discussed. Before the era of aseptic surgery and bacteriology a great variety of methods were alternately used, abandoned and resumed. Puncture with the trochar, aspiration, intercostal incision, puncture and injection of antiseptics, continuous irrigation, etc., were alternately lauded and rejected. Ingenious tubes, complicated instruments and theoretical appliances were proposed. Indeed, the practical surgeon must still be astounded at the antiquated assertions and loose advice still prevalent in many textbooks. At present we know there are empyemas and empyemas. Certain benign infections are easily cured by means wholly inefficient in others. In our present light the indications for rational treatment appear to be clear and fairly definitely established. A very few yield to paracentesis, and a certain other few are, perhaps, best treated expectantly so far as operation is concerned. It is also well known that certain benign effusions may be successfully drained by simple intercostal incision without rib resection, especially in children, and yet this operation is rarely advisable. Thus, the normal procedure for acute empyema is thoracotomy with resection of a rib. This should be the rule, because it alone is adequate to the best treatment of the vast majority of cases, and because skilfully done it is scarcely more difficult or dangerous *per se* than the less efficient drainage of simple intercostal incision.

The drainage opening should be large enough to allow of the removal of all clots and débris, to admit of careful examination of the cavity, even in some cases to allow of inspection by reflected light, and to remain thoroughly open until the cavity under ordinary circumstances may be expected to close. To these ends it is well to resect 6 centimeters of a rib, which admits of the introduction of three fingers. Personally, in certain cases where the conditions found indicate that a very prolonged drainage will be necessary, I occasionally resect two ribs, simply with the idea of establishing a lasting free drainage and keeping the cavity under inspection during its closure. This is, of course, unnecessary in simple acute cases. In my experience, especially in the past, the drainage opening is made too small ten times where it is once made unnecessarily large. The difference in traumatism between making a small opening and one admitting three fingers and giving full command of the cavity is little, but the difference in efficiency is great. I would make three exceptions to this rule of rib resection as the normal procedure in acute empyemas:

1. In pure pneumococcic pleurisies, thoracentesis may be tried, and it not rarely succeeds. This variety is more frequent in childhood—hence, the frequently reported cases by aspiration and small drainage in children. This fact, together with the greater intercostal space in these subjects, has led to a disposition to view the indications for treatment of empyema in children as differing from that of adults, a contention without much foundation, and unless it be in very young infants, rib resection should be the rule. I have met with only two cases of pure pneumococcic pleurisy in adults. In one, a young man, a single aspiration of three pints of a light white pus was followed by prompt and complete cure. When the history of the case and the appearance of the exudate point to a probable pure pneumococcic infection, drainage should be delayed, and if bacterial examination confirms the suspicion, even a second, possibly a third evacuation by the aspirator may be tried before opening the chest.

2. There are certain pure tuberculous pleurisies in which drainage should be delayed until the advent of mixed infection. Tuberculous pleurisies are for the most part serous, until mixed infection occurs, when, as a rule, they are more or less benefited by free drainage. However, there are several varieties of tubercu-

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker and A. J. Ochsner

lous pleurisies as well as suppurating pleurisies in tuberculous patients, and it is a matter of good judgment rather than of set rules when to operate and when not. Briefly stated, I think the rule should be when the exudate withdrawn by the exploring needle is apparently sterile, or when there is little rise of temperature or evidence of sepsis, it should be left alone, or at most reduced somewhat from time to time by aspiration in case subjective symptoms arise, or the accumulation is increasing. This is especially the case in hemorrhagic tubercular effusions.

3. In large and double effusions, gradual evacuation by paracentesis is advisable as a preliminary measure, the rib resection being delayed a few hours. Or in double empyemas the rib resection may be made on one side and the siphon drainage of Bülau may be simultaneously instituted on the other.

ANESTHESIA.

In most cases the brief and light chloroform narcosis required for a rib resection is well borne, but if the general or cardiac conditions seem to contra-indicate chloroform, the operation, if dexterously performed, may be made with but little discomfort under local anesthesia (Schleich). Ether should not be used.

In operating under general anesthesia, the position on the table is of importance. In large effusions, and in cases which have already ruptured into a bronchus, the patient ought not to be placed upon the sound side; hence, a high table with the involved side drawn well over the edge, aids greatly in making a well-placed drainage.

As to the technique of the very simple operation of rib resection, there is but one point that occurs to me worth mentioning. Good bone forceps are undoubtedly the most handy instruments for section of the bone, but they sometimes disagreeably crush and fissure the rib. A much neater and smoother section is made by a Gigli's wire saw. Possibly the occasional neuralgias and some other rare sequelæ of rib resection might be avoided by this certainly more elegant method of resection.

LOCATION OF THE DRAINAGE.

In draining the pleural cavity the opening should be placed at the lower and posterior part of the collection, or rather at the point which is to become such as the cavity shrinks. Leaving out of consideration interlobular and supra-diaphragmatic collections, intra-pleural effusions vary considerably in their location in different cases, hence to place the drainage opening at any set place on the chest is manifestly absurd. It is doubtless a fact that purulent effusions most frequently occupy the lower and posterior portion of the pleural cavity; hence, in the majority of cases of empyema, the eighth rib, well back, just outside the angle of the scapula, is best chosen.

In the mid-axillary line and anterior to it the muscular covering is less thick than upon the latero-posterior aspect of the chest, and this naturally inclines the operator to choose a location which is often ill-placed. The usual dorsal position of the patient on the operating table further increases the difficulty of operating posterior to the mid-axillary line. An opening in this plane is quite sufficient for certain empyemas, but if the case is a bad one, i. e., a virulent infection, and the cavity large, I have often observed that the residual cavity, after a few days or weeks of drainage, is most often found to be upward and backward from openings placed low and forward. Hence, in most cases, a drainage placed moderately low and well posteriorly upon the unevacuated cavity proves most satisfactory during the latter course of the treatment. Indeed, in certain cases, the rib is best resected as far back as the angle. In at least three cases I have observed moderate-sized cavities located upwards and backwards under the scapula which could only be drained by such posterior-lateral incisions. In many cases drained by others or by myself, I have found after a short time that the opening came to be situated below and in front of the cavity, leading to the necessity of reopening further backward and upward. The rule ought to be to place the opening moderately low and well posteriorly upon the cavity. If it be too low, the diaphragm in certain cases soon rises over it and the drainage is soon imperfect and troublesome. I have never seen it placed too far backwards for the best results, but many times too far forwards. However, as a high posterior rib resection is a rather more formidable operation in certain cases, it is well to resect the eighth rib in the mid-axillary line as a primary measure, and some weeks later, if necessary, make a second higher and more posterior resection if required.

OF IRRIGATIONS.

After resecting the rib, the first opening through the pleura should be small so that a large part of the effusion may drain away slowly. When this has taken place the pleural incision is increased correspondingly to the piece of rib removed. Through this copious opening the cavity may be thoroughly cleansed by wiping out with bits of gauze on a long forceps. In case the condition of the patient demands it, this may be deferred to a subsequent time. Immediate irrigation of the cavity is often objectionable and always less efficacious than wiping out with gauze. In my opinion lavage of these cavities has a very limited field of usefulness. Two things are quite clear: 1, with the chest opened as freely as here indicated, frequent irrigations are not necessary; 2, the injection of empyemic cavities through small openings is decidedly dangerous. Sudden deaths, syncope, embolism, paralysis, various nervous phenomena, etc., which have been long observed and much discussed, are undoubtedly the most striking, but not the most frequent accidents of irrigation. Rises of temperature and various septic phenomena and complications very frequently follow too diligent lavage of these cavities. The smaller the opening and the more forcible the injection, the greater the liability to these various accidents. I have never seen any serious accident follow the gentle lavage of freely opened cavities, but I have come to believe that they do better with a minimum of irrigating. The idea of stamping out infection by the use of antiseptic washes is no longer rational. A few days after the free opening of a cavity peroxid may occasionally be poured over its walls or applied with a swab of cotton, or it may be washed out with warm bland solution if desired. The indications usually given for lavage are: 1, abundant purulent secretion; 2, fetid secretion; 3, if the fever persists or reappears after a period of apyrexia. It may surely be debated whether lavage avails anything against either of these indications. I am certain that it is a frequent cause of the latter condition, i. e., persistence or reappearance of the fever, and I have repeatedly known the temperature to subside when lavage was stopped. When a cavity can not be kept clean without much lavage, it usually needs to be reopened more freely. It is better to devote greater care to external cleansing of the wound and skin, and to the occlusion dressing and less to the diligent squirting of quarts of fluid into these cavities. When the secretions increase or become foul, the cavity ceases to shrink, and the opening has become small, free reopening is usually followed by general and local improvement, whereas the most diligent syringing shows little if any beneficial results.

DRAINAGE TUBES.

With a large opening of the chest the chief object of the drain is to keep the wound from closing. When the bottom has been taken out of the reservoir, draining away of the secretion can scarcely be prevented. With a small hole entering the cavity at some point on its external wall, often with clots and débris retained, it can scarcely be kept clean with an irritating drainage tube. For the purpose of keeping the wound open and its lips in a good healthy condition, copious gauze drainage is preferable in most cases, at least in the early after-treatment. When the amount of secretion is great, rubber tubes surrounded by gauze may be preferable. There are many objections to exclusively tube drainage in these cases: 1. The wound is encouraged to close down rapidly and the command over the cavity by direct inspection is lost. 2. The pressure of the tube exercises a bad influence on the soft tissues. The tract occupied by a tube is usually in an unhealthy condition, in marked contrast to that of a large wound held open by sterile and iodoform gauze. There are doubtless stages and conditions in the course of the treatment of empyemas in which tubes are very useful, but I find myself using them less and less. When desirable, two large soft-rubber tubes placed side by side may be used. They should be of the size of the thumb, short, and not press upon the pleura. Great care is necessary in their daily sterilization, and some contrivance to secure against their loss in the chest must be instituted. When small openings were in vogue, nearly half the cases coming under my observation were found to have lost tubes in the chest. The many ingeniously devised drainage tubes are absolutely superfluous, to say the least. Valvular drainage tubes, as proposed by Williams and others, with the idea of expanding the lung during inspiration, are certainly not necessary and of doubtful efficiency. In empyema when the chest is opened the collapsed organ is expanded by air from the sound lung during expiration and in coughing. And this force is apparently much more effective than inspiratory efforts with the chest closed by a valve. If tubes are to be used for chest drainage none are better than those manufactured on the spot from sterile pure soft-rubber tubing, but personally I prefer gauze drainage for the most part and use tube drainage only in stages and cases where it seems more expedient. Many cases may be drained all through by gauze. More frequently after a time, when the cavity has become small, tubes are substituted with advantage. At times it is necessary to drain a considerable cavity through a small opening on account of the condition of the patient, in which case tubes are quite indispensable, but as a rule such a cavity needs a freer opening.

DRESSINGS AND AFTER-CARE.

The dressing of empyema cases is often very careless. These patients being ambulant most of the time, are often allowed to shift for themselves, and the after-treatment is anything but aseptic. Strictly speaking, a careful aseptic occlusion dressing ought to be maintained throughout the treatment from the first opening to the closure of the cavity. How rarely this is achieved we all know. While the dangers of seriously reinfecting an old granulating cavity are not great, such accidents may often be observed in the most chronic cases and doubtless sometimes occur in the early stages of acute cases, when a comparatively benign infection is rendered more virulent by the entrance of infection from without. Patients and attendants should be more impressed with the necessity for a rigid aseptic after-treatment of these cases. While the discharge is free the dressings should be changed as often as they become saturated, and during the whole after-treatment at least once a day.

Besides the general attention directed to the constitution and the local care of the wound, a third matter ought to receive constant consideration, viz., the progress of the expansion of the collapsed lung. During the early days of the after-treatment, cough tends to this end; hence, it should not be too far subdued by narcotics. If, after the patient has had time to recuperate, it is found that the lung is slow in expanding, means should be instituted to assist it. Until the cavity has nearly closed, forced expiration is the most efficient and practical means at our disposal, and the patient should be instructed in methodical forced expiratory movements with closed glottis. The suggestion of Koenig to require such patients to blow up air pillows several times daily is practical.

THE PROGNOSIS.

The prognosis as regards life naturally depends upon the nature and extent of the infection, and the resistance of the individual. As regards closure of the cavity, it may be said, I think, that acute empyemas, promptly recognized, freely and adequately drained, and aseptically treated, as a rule close in from three to twelve weeks. As the treatment of empyema becomes more rational, thorough and scientific, incurable fistulæ and cavities become more rare; in fact, the exception.

CHRONIC EMPYEMA.

However, some cases for various reasons become chronic, and the cavities are closed only with difficulty and after months of invalidism, and the performance of more or less extensive plastic operations. In a few, owing to feeble general health or tuberculosis, the final closure of a small sinus may be indefinitely postponed. Plastic operations should not be undertaken until the cavity has been reduced as far as possible by free drainage, general improvement of health and respiratory gymnastics. It is usually several months from the time of the primary opening before shrinkage of the cavity comes to an absolute standstill, when, if the general state warrants, thoracoplasty may be undertaken. When after long drainage the lung has expanded to the fullest extent possible, the mediastinum has been displaced, the diaphragm has risen, and the chest wall has fallen in until the ribs are in contact and a cavity or sinus still remains, it is evident that some other principle than drainage must be called into action if the cavity is to be finally closed. The idea of the surgeons who first attempted to close these chronic cavities seems to have been that closure is chiefly prevented by the rigidity of the ribs; hence, Estlander in 1877 proposed to mobilize the thoracic wall by resecting that portion of the ribs covering the cavity. In practice the cause of failure of most of these cavities to close is to be found rather in the pleura than in the ribs. The walls of these persistent cavities and fistulæ become indolent and quite analogous to the edges of certain old indolent ulcers, and removal of the superimposed ribs alone rarely proves entirely successful in their complete closure. Hence, this type of thoracoplasty has been superseded by the Schede type of operation, in which the whole chest wall, save the skin, is removed over the cavity. Of late years cases requiring extensive plastic operations are much less frequent than ten or fifteen years ago, but in five cases during the past six years I have found it necessary to remove more or less extensive portions of the chest wall, and secured complete and prompt closure in such instance, whereas ten or fifteen years ago a much larger number of operations of the Estlander type were observed, in the majority of which sinuses remained as long as the cases were followed. Thus, with prompt and efficient treatment of acute empyemas, chronic cavities and fistulæ are rare, and these may with few exceptions be closed fairly promptly by thoracoplasty. When the general state is very feeble, when amyloid disease is advanced, when the cavity is enormous, failure is probable, but there are few absolute contra-indications to a well-timed attempt to close these chronic cavities. Tuberculosis is unfavorable, but by no means an absolute contra-indication.

DISCUSSION ON PAPERS OF DRS. WILLARD AND DUNN.

Dr. A. C. Bernays, St. Louis—Pneumotomy and pneumectomy are the operations which deal with tuberculosis—first and last and all the time with tuberculosis, excepting, perhaps, a few cases where a surgeon would be called early enough to render aid in a traumatism from a gunshot wound or a stab in the chest. We are gradually encroaching on the domain of the medical men so much that soon our fellows may not have their lungs left. I really believe the time is at hand when we are going to attack the ravages of tuberculosis in the lungs with our surgical technic, and I believe we are going to do it successfully in many cases. In order not to discourage our efforts, we should carefully select suitable cases. It is a fact that pure infection by tubercle can recover spontaneously or by means of dietetic and climatic treatment. We all know that to be a fact, because we have all examined the sputa of tubercular patients and have seen them recover from dietetic and climatic treatment. In those cases prognosis is favorable as long as there is no mixed infection. As long as the patient has only the growth of tubercular bacilli in his lungs he may recover spontaneously, but in most cases there will soon be a mixed infection; that is what kills and that is what I think we can attack surgically. When there has been a secondary infection of the tuberculous patient by staphylococcus, streptococcus, colon bacillus, and other pathogenic microbes, or some of the saprophytic microbes, then our treatment must aim at their exclusion. Cavities in the lung are the points of attack. In considering their treatment, the question is simply this: Is the danger of the operation less than the expected benefit? Then the procedure is justified even if it is not a radical treatment. We must select cases that are not beyond the stage where recuperation is possible, just as we do in carcinoma. Cases in which a cavity in the lungs is the most prominent danger are rare, but if we can only bring one in a hundred of these unfortunates back to health, the operation of pneumotomy must appear as a justifiable operation. Just before I came here I had the superintendent of a public hospital send for me to see ten cases of death from consumption and in those ten cases I, with the aid of my assistants, went to the dead house and removed all of the soft parts over the top of the lungs on both sides, removing the whole clavicle, the first, second, and third ribs and then examined the tops of both lungs; the most interesting thing I found was that I could peel out with an elevator and with my fingers, the apices of the lung on both sides in eight out of ten cases without causing the pneumothorax. It was possible, by a blunt instrument, and with the fingers to peel out the upper part of the lung, in eight out of ten cases so that the lower part of the pleural cavity was not opened and there was no chance of producing a pneumothorax. While I was doing that postmortem work, of course I had in view an operation which I could do upon a living patient and I believe that the best operation to be done in a case of that kind will be the following: Make an incision, beginning at the margin of the sternum and running through the pectoralis major muscle 5½ inches laterally in a straight line down to the second rib. Some French surgeons have advised making an incision over the first rib, but I think that is a mistake. The incision over the second rib gives much more room and is easier done. By means of the finger or a blunt instrument the pectoralis major muscle and soft parts are scraped off the ribs upwards and downwards. Then, by putting in a broad retractor, such as we use in the abdominal cavity in each side, the edges can be spread out and the second rib exposed for 5 inches. Another retractor placed into the lateral edge of the wound, will rest upon the axillary vessels and brachial plexus, but it will completely protect them so that, with the greatest ease, the second rib can be resected. I note that whenever I made a cut through the cartilage, the rib would stand out and then it is only necessary to use the wire saw or bone forceps, or even only to pull upon the medial end until it breaks off near its angle. All you have to do is to take hold of the second rib and break it off; it will break at its weakest point near the axillary line. It is not necessary to use bone forceps, but the second rib is taken hold of firmly and broken off, leaving not a ragged, but always a transverse break. You will have before you the white, almost bloodless, cicatricial-looking fibrous layer of tissue, the two layers of pleura having adhered, and you will find it not only difficult but requiring force with your fingers to loosen the cupola—the apex of the lung—out of its adhesions. Having loosened it clear around behind, on the sides and in front, then the finger will easily detect the fluctuation of the cavity; this cavity I would not open with the Pacquelin cautery, but with a knife. There is little danger of hemorrhage in the peripheral part of the lung. The top part particularly is not supplied with large arteries. The blood in them is under a low pressure and you can push your knife, or if you please, if you are in the tentative stage of surgery, you can push a thick trocar in there until you find the pus cavity. Having found the pus cavity, it should be opened by the method of Mr. Hilton. You remember he gave a method for the general practitioner to open abscesses, a method which avoids hemorrhage. After making the cut, press the dressing forceps into the cut, and enlarge the opening by separating the handles of the dressing forceps. In that way the abscess cavity can be widely opened and can be treated in any way that the operator may choose. In these cases that I examined very carefully I found that on the inside of the cavity you could see large blood vessels covered merely by a little pyogenic membrane, ready to burst. I found this in all the cavities I opened. Whether it would be well to tie those vessels with catgut or silk, I do not know. In this department of surgery we depend largely upon our theoretical studies. It would be a perfectly safe operation if in such a case as that you did not produce a pneumothorax but succeeded in getting into a cavity, to treat that part of the human body exactly as you would treat a case of pyonephrosis, appendiceal abscess, or abscess of the liver. The fever is caused by the pus, not by the tubercle bacilli, but by the secondary infection with pyogenic bacteria. You can drain the cavities and the patient's temperature will become normal rapidly. If he has a cavity also on the other side, it will not become normal until you open the other side. Dr. Willard covered the ground of treatment of foreign bodies in the air passages completely.

The first and important statement Dr. Dunn made was that the treatment of empyema depends upon microscopic findings in the fluid that have been brought out by the exploring needle. The condition demands that a microscopic examination must be made and the treatment must be governed by the findings of what is withdrawn with the exploring needle. One point that I never heard before was the use of the wire saw for the purpose of cutting out the ribs. I shall undoubtedly adopt that plan, for that will prevent ragged and jagged edges. In regard to irrigation, I find myself absolutely in agreement and will only mention it in order to emphasize my position. I used to be a great irrigator, but I have absolutely abandoned irrigation, both in empyema cases and abscess of the liver, or in appendiceal or pelvic abscesses of any kind. It is a principle of surgery that where we have complete and free drainage we don't need irrigation. After drainage of an abscess, if fever arises, you can not cure that fever permanently by irrigation. What is indicated is to make the hole larger or make another hole in another place.

Dr. J. H. Barbat, San Francisco—I have been experimenting on dogs during the past year in the endeavor to solve some of the problems in thoracic surgery. I was unable to obtain any of the insufflation apparatus, and so had one constructed, which worked very successfully. It consists of a bellows with a spring, which can be adjusted so as to regulate the amount of air in each insufflation. The air is passed through a wash bottle containing hot water, so as to remove all dust and also warm it, thereby lessening the possibility of irritating the bronchial mucous membrane. A second bottle is provided with a two-way cock, which allows us to pass the air from the bellows either direct to the lungs, or to pass it through chloroform or ether, thus regulating the amount of anesthetic perfectly. I found in my experiments that it was easier in the dog to use a tracheotomy tube than an O'Dwyer tube. By anesthetizing the dog first, the tracheotomy tube was easily introduced, and then the insufflation and anesthetic could be kept up during the operation with comparative ease. To enter the chest cavity I make an osteoplastic flap by cutting through the requisite number of ribs near their attachment to the costal cartilages with a modified gardener's pruning shear, the cutting blade of which is thin and sharp, thus avoiding crushing the ribs. The next step consists in passing a full curved needle armed with heavy silk through the skin and around the rib, being careful to avoid including the intercostal vessels and nerve, at a point three or four inches back of the first cut. A Gigli-Haertel saw is then pulled through by means of the silk, and with two or three strokes of the saw the rib is weakened. All the ribs previously cut being treated in the same way, it is easy to turn back a large flap, without having seriously interfered with the circulation, which allows us to work with freedom on the contents of the chest cavity. In resecting the lung the electro-hemostatic forceps of Skene may be used instead of the angiotribe, the only disadvantage being that it is necessary to carry the electrical apparatus with you while the angiotribe is complete in itself. In resecting a rib for empyema, time is an important factor, and I have found that the operation may be expedited by using Doyen's periosteotome, which consists of a piece of narrow half-round steel, one end of which is bent in the shape of the letter C and set at right angles to the shank. After cutting through the soft parts and periosteum with one stroke of the knife, the free end of the periosteotome is passed under the periosteum and worked up over the top of the rib, then down behind, avoiding the vessels and nerve, then out in front of the lower border of the rib. The shape of the instrument is such that when it is in position it fits the rib closely and all that is necessary to do is to move it back and forth a few times to loosen the periosteum perfectly, then with the sharp cutting shears the rib is divided, and the whole operation completed in from three to five minutes.

Dr. W. Jepson, Sioux City—In connection with the subject presented by Dr. Willard, I believe that there are few subjects in the whole domain of surgery where it is so essential that a clear conception should exist regarding what to do and how to do it, as when treating foreign bodies in the air passages. The statistics as collected by Gross, Weist and others, indicate that about 24 per cent. die when not operated upon. This is certainly a large mortality and must place this condition among the graver accidents; however, the saddest fact revealed by statistics covering a large number of cases is that more die when operated on than when not. Thus, of 1000 cases collected by Weist in 1878 or 1880, it is shown that the mortality was increased 4 per cent. by the employment of operative measures for the removal of the foreign body. Notwithstanding the sad results of operative interference in these cases, I say that Gross uttered an axiom when he, some forty-five years ago, stated that when a foreign body existed in the air passages, the trachea should be opened to facilitate its removal. This opinion was based upon his own personal experience, which showed that 17 per cent. more recovered when operated upon than when left alone. From a personal experience of 16 cases, 15 of which were operated upon with recovery in each instance, I advocate that, with few exceptions, where a foreign body has gained access to the trachea or bronchi, the trachea should be opened as soon as possible to facilitate its removal. It was said that the symptoms were often indefinite and vague. How true this is we quickly learn after even a limited experience with these cases; the phenomena occasioned by their presence may simulate those occasioned by any of the various affections of the respiratory tract, and it therefore behooves us not to overlook their presence. I seriously doubt if the employment of emetics, sternutaments, or inverting the patient and slapping upon the back, or other measures calculated to increase the expiratory force with a view of dislodging and expelling the body, are proper measures to employ. I recognize that now and then it may possibly be fruitful of the object aimed at, yet how often does it not fail and possibly with dire results. The upper third of the larynx is supplied by the superior laryngeal nerve, irritation of which may, through its relationship with vagus, lead to cardiac and respiratory inhibition, which may be most serious. We see this fact unconsciously recognized on the part of parents of children having seeds of corn, etc., in their air passages, by maintaining them in an upright posture so that the gravity of the foreign body keeps it out of the larynx, thus avoiding those violent attacks of coughing and choking.

The question of greatest importance pertains to the procedure of removing the foreign body after the trachea is opened. Foreign bodies in the air passages may be divided into two classes: 1, those which are movable within the lumen of the trachea or bronchi, bodies which are generally possessed of a more or less smooth surface, as seeds of corn, beans, coffee beans, etc.; 2, those which have become fixed in some part of the air passages, bodies which are generally irregular in shape, as tacks, pins, sand-burs, etc. Of course, a smooth body may become impacted in the larynx or either of the bronchi. After opening the trachea we readily recognize by the character of the breathing as to whether the body is distal or proximal, and are thus guided. If in the larynx, its removal can generally readily be accomplished by a suitable pair of forceps. If the body is located in the lower part of the trachea or a bronchus, especially if the same be hard and smooth as in the instance of many seeds, I doubt if we are warranted in making any attempt to grasp such a body with any forceps which we now possess. We would be much more likely to force it on down into the constantly diminishing lumen of a bronchi and thus impact it, making its subsequent removal very difficult if not impossible. The resistance offered by the trachea or bronchus to smooth bodies is not great until they are impacted, but it is necessary to grasp these bodies. All that it is necessary to do is to loosen them if impacted, when the expiratory current of air will carry them to the tracheal opening, and, if the trachea be slightly angulated by means of a pair of catch forceps or a loop of thread in each edge of the tracheal wound, the body will be ejected, or brought to the wound where it may be readily grasped. To loosen such bodies when fixed or impacted, no more efficient means can be employed, with possibly few exceptions, than that simple expedient of taking two or three strands of fine steel wire and twisting them together, leaving loops which may be passed beyond the object to loosen it on the withdrawal of the loops. A wire with a hook on its end and a half-circle higher up to keep the hook in the lumen of the passage, may at times be used to much advantage. No doubt the coughing excited by the passing of the wire loops is a potent factor in many instances in loosening the foreign body. I concur in the view expressed by Dr. Willard that the simple opening of the trachea can not add to the risks of the patient; therefore, the large mortality in these cases, as shown by statistics quoted, must be due to other causes; probably because operative procedures were instituted too late or unwarranted instrumentation was employed and injury resulted.

Dr. Jacob Frank, Chicago—I have had considerable experience with two unpublished cases of lung surgery, and I have found from these and from experiments on dogs, that lung surgery is not so easy as most speakers would lead us to believe, with the exception of Dr. Willard. The first case was that of an abscess in the upper part of the right lung. I should say that it was an abscess of the lung, because the patient under anesthesia had frothy blood coming from his mouth. That is one of the signs and also one of the dangers in operations on the lung which has not been mentioned here, that is, drowning of the patient in his own blood. I worked my way down to it by resecting the clavicle and part of the first rib before coming to the abscess. This patient made a recovery. We introduced a syringe with a catheter, made suction, and the patient recovered. The second case that I had was that of a little boy who periodically would vomit from a quarter to a half a glass of pus. It could be distinctly determined on percussion when the abscess cavity was full and when it was empty. I thought it best to operate when the abscess cavity was full, but unfortunately when he was taking the anesthesia he vomited the pus. I resected the ribs and poked around with a needle twenty or thirty times until the blood came out of the boy's mouth and he was almost suffocated. I had the cavity soon cleared of the blood, and then worked my way with an artery forceps to find the cavity, and I failed. I am sure that I made enough laceration of the lung to find it, and can not say why I failed. The boy died. In lung surgery we stand to-day where surgery did twenty years ago in tuberculosis of the joints, first the resections and then afterwards getting to the curettement. I can not see the benefit of resection or excising any portion of a tubercular lung, unless we are sure there are not any tubercles a quarter or an eighth of an inch just beyond the border of the removed part, and I do not think that surgery of the lungs will ever become prominent—that is, excision for tuberculosis—unless we have some means to determine that there are no tubercles in any other part of the lungs. There is a difference whether we have a deep abscess of the lung to operate on without any adhesions of the pleura and the chest walls, or whether it is superficial. Merely an abscess, where there are adhesions already, is not more difficult to open than any other abscess.

Dr. Lemoyne Wills, Los Angeles—There is much opposition to anything in the way of draining superficial cavities, or any operating on the chest until it is too late to do good. It is for the profession to overcome that opposition and not to allow their patients to go on in a septic, dying condition and then send them away to Arizona and New Mexico and Southern California, allowing the responsibility to be shifted to other men's shoulders and obliging the latter to sign the death certificate. That is the condition in which we get them. If you would diagnose your cases properly, treat them properly, as in operations on the brain and abdominal cavity, there would be more cases cured and fewer suffering consumptives in the last stages sent West to die. I am agreed with Dr. Frank that this is a matter of diagnosis. It is a matter of great care in the selection of your cases, but if you have a case almost moribund, with tubercle bacilli in sputum and a single large cavity in the posterior lower lobe, and can drain it, and if the man gets well and goes back to active life at his trade and puts on 75 pounds of flesh, that is certainly hopeful for the future of such operative treatment. If your patient is willing to submit to operation, knowing the dangers, the surgeon should be willing to take the risk even if as low a percentage as one in a hundred is cured.

Dr. C. H. Norred, Minneapolis—I simply want to relate a case, not operated upon, that made a brilliant recovery. In 1869 a child between 2 and 3 years of age, in running, drew a peanut kernel into the bifurcation. At that time we were not operating upon the lungs, and I treated the case expectantly. The patient, however, developed a typhoid pneumonia, and I called to my assistance Drs. Burrough and Henry, of Springfield, Ill. They assured me that my patient was beyond help. I noticed that in the paroxysms of coughing the child would get the peanut kernel up just so far and a spasmodic contraction would take place, everything would stop and cease and a desperate strangulation would result. I suggested that we relax the patient most completely, then give the child an emetic. The child was given morphia; we provoked vomiting and secured in a bowl the peanut. We finally succeeded in handling the complications and the child recovered.

Dr. W. W. Keen, Philadelphia—Some time since I had occasion to attempt to reach a cavity in the lung that was filled with pus, and I made the incision at the point that was indicated by my medical colleague after percussion of the lung, between the second and third ribs on the right side. I made my incision parallel to the ribs for about two inches; then carefully dissecting the muscles, separating them as I went down, with a cut and separation, I reached the pleura, which was very easily recognized. The muscles were very easily separated from the pleura. I could see the excursion of the lung up and down as it fell away to a certain extent from the surface. As there were no adhesions it was clear that it would be unsafe to puncture the lungs if there was any pus there. Accordingly, when the lung was at the moment of rest between inspiration and expiration, I took a Hagedorn needle and passed it quickly through the lung itself. Two stitches secured the lung in position. I then packed the wound lightly with iodoform gauze and closed it with two stitches. After three days I reopened the wound, removed the packing and had the gratification of finding a perfectly adherent lung.

This led me still further some time since, in a case that I reported at the American Surgical Association. It was the case of a woman who had sarcoma of the chest wall, reaching from the outer border of the breast nearly all the way back to the vertebral column, and I was obliged to remove a portion of the chest wall, into which my hand would precisely fit. When this was removed the lung collapsed. I had the Fell-O'Dwyer apparatus ready for use, but fortunately in this case there was very little embarrassment of the respiration as a result of the collapse of the lung. I then introduced my left hand and seized the lung bodily—it was not invaded by the tumor—drew it forward and with a long thread of catgut and a Hagedorn needle, sutured the lung completely around the opening by a continuous suture, with a view of preventing, as far as possible, pneumothorax. Then, I replaced the flap of skin and sutured it and sealed with iodoform and collodion. The patient made a fair recovery from the operation, but had a continued fever, which led me to have a blood examination made, and I found the staphylococcus infection in the blood. This was met by the use of the antistreptococcus serum, and the patient made a complete and very satisfactory recovery. The point I wish to emphasize is the means of obtaining adhesions where none exist so that we can carry out later in a punctured lung that which may be necessary, and secondly the safety even of a very large suture of the lung tissue to the chest wall, either as in the first case locally, or, as in the second, where there is a very large area in its surface.

Dr. W. J. Means, Columbus—In the last two years I have had several cases of chest and lung troubles on which I operated. One of these cases demonstrated the possibility of recovery after a fearful gunshot wound penetrating the chest and producing extensive laceration of the lung. A boy, 16 years old, was out hunting with an old-fashioned muzzle-loading shotgun. It was accidentally discharged and the charge entered the chest below the axilla. The sixth and seventh ribs were broken, and the middle and lower lobes of the lung lacerated. The pleural cavity, when I saw him, was largely distended with blood clots. The opening was enlarged so that I could introduce my hand. When the débris was removed there was a very decided collapse. For a few minutes it looked as though death was imminent. To control the hemorrhage I packed the cavity with iodoform gauze; several yards were used. The heart soon became stronger and the respirations more rhythmical and full. The packing was removed forty-eight hours later, when the same alarming symptoms appeared, and disappeared on repacking the cavity. This phenomenon was present at every removal of the packing for some two weeks. This seems to have been a practical demonstration of the physiologic principle of the effects of destroying the equilibrium in the viscera of the chest. I recall another case illustrating the difficulty in the way of reaching an abscess cavity in the lung. The location of the abscess had been defined by an expert diagnostician. An opening was made in the chest wall corresponding with the supposed abscess. The pleural surfaces were found adherent, but no cavity. The patient had been expectorating an offensive pus for some time. The lung was explored in different directions, but no cavity could be located. The lung tissue at the point of opening was diseased and undergoing degeneration. A large opening was made through the chest wall and drainage established into the diseased lung substance. At intervals of forty-eight hours the diseased area was injected with iodoform emulsion. The patient recovered from the operation, but died four or five months later. I mention this to illustrate the difficulty in locating a cavity, and the fact that local treatment of tubercular areas of the lung will not always control the disease.

Dr. De Forest Willard, in reply—When the foreign body is not removed septic pneumonia frequently results with the formation of an abscess. Such an abscess should be opened and drained. Adhesions can be speedily produced between the two walls of the pleura so as to close off the pleural cavity before opening an abscess. With a strongly curved perineal needle with handle, a parallelogram of sutures can be carried around the area and the abscess opened at once, or twenty-four hours later. The same method may be employed in opening abscesses in the liver through the chest wall. A rib should first be resected subperiosteally, then a small amount of air should be allowed to enter the pleural cavity so as to permit the lung to recede slightly. The outer surface of the pleura and the diaphragmatic layer should then be sutured as above described, after which the liver can be reached across the pleural space, and pus evacuated without infecting the pleural cavity.

In regard to resection of the ribs, which has been alluded to this afternoon, I never use the bone forceps, since they are clumsy and are very likely to wound the pleura. With an extra-heavy flat-bladed rongeur forceps a rib can be cut through in a moment, turned back, and lifted out for any distance desired for resection, the second section of the bone being made with the same rongeurs.

THE TREATMENT OF STRABISMUS OTHER THAN OPERATIVE.[*]

EDWARD JACKSON, A.M., M.D.

Ophthalmologist to the Arapahoe County Hospital; Consultant in Ophthalmology to St. Anthony's Hospital, Denver; Emeritus Professor of Diseases of the Eye, Philadelphia Polyclinic.

DENVER, COLO.

Important as is the operative treatment of squint, it is less widely applicable than the non-operative treatment. A large proportion of cases may be cured without operation. The number so cured will increase, as it becomes customary to resort to the proper measures, as soon as the deviation is noticed. But in all cases some non-operative treatment is essential to effect a perfect cure. It may not be required only in that small class of operative cases in which binocular vision and normal ocular movements are not hoped for; but in which by operation we may lessen a deformity that we can not wholly remove.

The non-operative treatment for strabismus includes the entire treatment of many cases, and the earliest treatment for all. The indications to be met by it are: 1, to bring about normal innervation of the muscles concerned in ocular movements, by the removal and exclusion of abnormal requirements, and abnormal overflow impulses; 2, to place and keep the eyes, so far as possible, upon the best plane of visual acuteness and an equality of required effort; 3, to eradicate abnormal methods of using the eyes, especially dependence upon one eye to the practical exclusion of the other; 4, to develop normal binocular vision—the method of combining the visual sensations produced by the two eyes; and the habit of employing them both in all ordinary seeing.

For the majority of cases, the time for this treatment begins as soon as the squint is first noticed. The problem of controlling the activities of a young child, and directing them along certain lines, is indeed a difficult one. But since the nerve-muscle apparatus that we are endeavoring to perfect is thoroughly plastic only during the earliest years, these difficulties must be grappled with. In the main, what I have to say in this paper deals with this most important phase of the subject. The modifications advisable for more developed patients can be very briefly indicated.

The aim of the non-operative treatment, as it is the highest aim of the operative treatment of strabismus, is the establishment of binocular vision. Of this there are many grades, beginning with consciousness of impressions made on the two eyes, and extending up to the most perfect appreciation of relative distance and relief. Probably something like binocular vision, something more than mere extension of the field by the squinting eye, exists in many cases of strabismus and may constitute an obstacle to the cure of squint. It is certain that binocular vision is possible even when the vision in one eye is extremely imperfect.

In a patient suffering from high myopia, whose vision with correcting lenses was 4/80 in the right eye and 4/9 partly in the left, were recently encountered all the difficulties of adaptation that one would expect when prescribing lenses of unequal strength for eyes with perfect vision. In a young woman whose vision in the right eye was reduced to counting fingers at 8 feet, while in the left eye it was 4/4 mostly, repeated trials of lenses correcting a part of her anisometropia ended in failure. The disturbances of binocular vision were so marked that she would not wear them. In cases of this kind, the usual tests for binocular vision may bring no response. But we can not doubt that binocular vision of a kind is thoroughly established.

The things to be accomplished in the treatment of strabismus may be classified thus: 1. The removal so far as possible of all obstacles to binocular vision. Under this head falls the operative, with a very important part of the non-operative treatment. 2. The establishment of binocular vision. 3. The perfecting of binocular vision. The latter two are to be effected wholly by the non-operative treatment.

When the patient is able to perceive simultaneously impressions made on the two eyes, binocular vision of some kind exists. The efficiency of the function is at first to be estimated by the ability to keep fused the images, under varied conditions of accommodation and convergence. Mr. C. Worth makes the ability to do this the second stage in the development of binocular vision. But I think that some power of maintaining fusion with altered accommodation or convergence begins as soon as there is ability to accomplish real fusion, although at first this power of maintaining fusion is very slight.

---

[*] Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

The development of the higher grades of binocular visual ability requires almost infinite practice. It may be compared in this respect with the higher grades of ability to play the piano or violin, or the mastery of the most delicate modulations of the voice. It must be acquired through the habitual use of the eyes in daily life; with such aid from glasses or suggested methods as we can give. It will not be reached merely through prescribed special exercises. With such exercises and the apparatus they require, we can only aim to bring about the rudest kind of binocular vision, and start it on the proper lines of development; although, in spite of the limitations of their usefulness, we must consider the most valuable of these appliances and prescribed methods.

Lenses.—In practical importance correcting lenses far outweigh all other measures for the non-operative treatment of squint. They remove the most common and serious obstacles to binocular vision that are removable. Their determination and use is the first step in the treatment of all cases. We can not in this discussion consider all the special indications to be met by lenses. But in every case the lenses should accurately correct all of the ametropia. Such lenses should be worn until the complete cure of the squint, or complete failure to benefit, shows them to be no longer necessary. Failure to rightly employ lenses is the most common cause of failure to cure strabismus. A very large proportion of the failures of glasses to cure strabismus in the earlier years of life must be ascribed to the fact that the glasses do not correct the ametropia. In many of these cases the glasses have been fitted by opticians. But even when prescribed by ophthalmologists of reputation and experience, one can not be sure that they are "correcting" lenses.

Case 1.—I. A., aged 6, was seen in consultation with a careful surgeon of large experience in ophthalmic work, who had prescribed R. and L. +2.75 spherical. These had been worn about five months without any marked diminution of a high convergent squint, which had during that time changed from intermittent to constant. The correcting lenses required were really

R. +4.50 ⊃ +0.50Cy. ax. 90°.
L. +5.50 ⊃ +0.50Cy. ax. 90°.

The wearing of these promptly checked the squint.

Case 2.—E. L. H., a girl aged 7, had been noticed to squint when less than 2 years old, and had been promptly placed under the care of an ophthalmologist. She had worn glasses for three or four years. Those she was wearing had been prescribed by an ophthalmologist who had seen her within a few months. After repeated examinations, he had given the opinion that glasses would do nothing more for her. That an operation was necessary; and unless he were allowed to do an operation he would not continue in charge of the case.

The child was wearing
R. +3 S. ⊃ +0.50Cy. ax. 90°.
L. +3 S.
What she really required was
R. +6.50 S. ⊃ +0.50Cy. ax. 105°.
L. +6 S.

These were prescribed and the deviation which had been 30 to 60 centrads promptly disappeared. At the end of six weeks there remained not over 5 centrads of esophoria; and in six months the muscle balance with the lenses on was perfect.

The accurate correction of ametropia being the most important single measure in the treatment of squint, and this being most effective in the earliest stage, it follows that no one who can not measure refraction objectively, no one who can not apply skiascopy with sufficient accuracy to obtain by it the data for prescribing lenses, is competent to treat strabismus.

This sounds like an extreme statement. Judging by old standards of attainment and old methods of treatment it is unduly so. But the experience of the last five years has established a new standard of success in the treatment of convergent strabismus in children, to be attained only by a method of which the foundation is the accurate correction of the refraction, at an age when the patient can give no assistance as to its measurement. In view of this, any milder statement simply falls short of the truth. The total hyperopia must be corrected. Astigmatism or anisometropia of 1 D. or less may constitute a complete bar to the re-establishment, or the renewed development of binocular vision, when the tendency to give up binocular vision has once become manifest. A fault of this kind, that would very rarely cause squint, may have to be corrected before the squint can be cured.

It may seem tedious to dwell so much on this subject of correcting refraction, but to have devoted more than three-fourths of this paper to it would only have been to give it space proportioned to its relative importance; and the cases I have cited illustrate a failure to recognize that importance which I believe is still very common among us.

Use of the Previously Deviating Eye.—In the great majority of cases this is the first point to be effected. Even though both eyes may to some extent be used, if one is distinctly preferred to the other for accurate seeing, the difference in the facility with which they are employed becomes a positive obstacle to the re-establishment of binocular vision. In general, it must be assumed that the fixing eye had originally some advantage over the deviating eye. To this advantage is added the facility acquired by habitual use for weeks, months or years. The advantage that the fixing eye now has is thus very much increased. It will not be removed by a few brief attempts to use the eye that has heretofore deviated. Weeks, months or years of continuous dependence upon the previously deviating eye might fairly be expected to be necessary to overcome such a disadvantage. In view of this, it is surprising what may be gained in this direction by a very moderate use of the poorer eye. But it should be understood that in most cases this using of the worse eye can not possibly be overdone.

The occlusion pad or bandage, which completely excludes the better eye, is the only thing that will serve the purpose, if the vision of the squinting eye is very much reduced. For older persons, it can often be used but a small part of the time, but for very young children it may be kept on almost constantly, removing it only often enough and long enough to ensure the health of the covered eye.

The essentials of such a pad are, that it shall absolutely prevent vision with the covered eye; and that it shall act as little as possible like a poultice. The ordinary roller bandage may be used, but generally some special form arranged with tapes will be found more available. If the child can be watched, a mass of absorbent cotton stuffed behind the correcting lens of the better eye will answer. But usually I find it better to hold the cotton in place by one or two strips of adhesive plaster, as with the simple dressing used after cataract extraction. To avoid the pulling on the skin when the plaster is removed, it may be applied to a piece that is left in contact with the skin continuously. The use of the occlusive pad should be continued until, if this be possible, the vision of the worse eye has so improved that it will be used for fixation when the other eye is kept under a cycloplegic.

The Use of Cycloplegics.—The so-called mydriatics are to be used in this connection for their power to produce cycloplegia, not merely to dilate the pupil. An enlarged pupil is not sufficient evidence that the drug is being used effectively. The slightest reaction of the pupil to light proves that the eye is not completely under the influence of the drug. It is necessary from time to time to test objectively the power of accommodation, or the absence of accommodation, to make sure that the cycloplegia is properly kept up.

In all cases, cycloplegia is required for the determination of the ametropia. It may then be continued in both eyes to prevent the abnormal innervation associated with accommodative effort. In cases of alternating squint, this is sometimes of particular value.

In monolateral squint, however, after the correction of the ametropia, the cycloplegia should more frequently be confined to the better eye. It thus serves as a means of compelling the use of the previously deviating eye. As above indicated, it can only be thus applied for those cases in which the paralysis of accommodation of the fixing eye, the other retaining its accommodation, causes the transfer of the squint. If cycloplegia of the better eye does not accomplish this, we must use the pad. But if it does cause the transfer of fixation, it is a measure superior to the pad, because it is constant in its influence, requires less attention, does not interfere with the health of the eye, and leaves binocular vision possible, under favorable circumstances, if there be a tendency to establish it.

When employed in this way, cycloplegia should be continued until fixation, even at a distance with correcting lenses, is most of the time done with the previously deviating eye, or until all gain in this direction has entirely ceased. The length of time that the mydriatics should be thus employed is somewhat proportioned to the age of the patient, or at least, to the duration of the strabismus. But it will usually extend to several months and may go on to years.

The use of a mydriatic formerly advocated, as a substitute for correcting lenses in children too young to wear glasses, is now a very limited one. Nearly all children old enough to have a decided strabismus, as distinguished from the irregular uncoördinated eye movements of infancy, are old enough to wear glasses. They will wear them without objection if the ametropia be high enough to be of much importance, and the eyes are kept under a mydriatic for a few days after the glasses are put on.

But the mydriatic can not fully replace correcting lenses. It may remove the tendencies associated with excessive effort of accommodation, but it does not bring up the vision of the poorer eye, or place it more nearly on a plane with its fellow, as regards effort necessary for use. It removes an important cause of squint, but it does not, like the correcting lenses, bring about the conditions most favorable to the development of binocular vision.

Exercises for the Development of Binocular Vision.—The first thing aimed at, is to induce the patient to see with both eyes at once. This is first to be effected by using most striking objects. The light used for the subjective measurement of squint or heterophoria is a good object to begin with. The bringing about of diplopia, measuring the separation of the images, varying their relative position with prisms, and their relative strength by the use of dark glasses before the better eye, are excellent exercises of this kind. For young children such exercises must be of the simplest character, and on this account the fusion tubes of Priestly Smith are of especial value. They are two entirely separate tubes to be held by the child, one in each hand. This giving of something for the hands to do, and the freedom of movement, and the variety of movements which may be made, aid in keeping up the child's interest in the exercises. Sometimes it may be necessary to enfeeble the image of the better eye by use of a dark glass, or of a piece of paper of the proper thickness and translucently pasted over the tube used for this eye. But generally if the two streaks can be seen no such modification is necessary.

The Reflecting Stereoscope.—Next to the fusion tubes may be placed Worth's modification of the reflecting stereoscope. It is more adaptable and more rudimentary than the ordinary stereoscope. It can be used for lateral deviations in the same way as the fusion tubes; and in the main it offers the exercises of a stereoscope. It furnishes employment for the child's hands, and the figures used with it may be indefinitely multiplied.

The Ordinary Stereoscope.—This is of service for certain very valuable exercises and its range of usefulness may be extended by employing specially prepared pictures. The ordinary stereoscopic lenses are so decentered that they act as prisms with the base out. The distance between the optical centers of the two lenses is about 85 mm. With an ordinary pupillary distance of 61 mm., this gives a decentering of 12 mm. for each lens; or with the 5 D. lenses usually employed gives a prismatic effect of 6 centrads for each eye. For children with a small distance between pupils, the decentering is still greater. For 55 mm. it would be 7.5 centrads prismatic effect. The pictures ordinarily used in the stereoscope are so broad, 85 mm., that the prismatic effect is required to render parallel the rays which enter the two eyes from corresponding points of the two pictures. If we make the pictures narrower, and bring them correspondingly closer together, the same prismatic effect will allow them to be seen with convergence. Thus, for a child with a distance between the pupils of 51 mm., pictures 51 mm. wide, placed in close contact, will have their corresponding points fused with a convergence of 34 centrads—almost 20°. These narrower pictures are very readily made by cutting down larger pictures, or in drawing the rude diagrams that often prove serviceable in the orthoptic training of young children.

The stereoscopes arranged for the adjustment of the width of the glasses, or the positions of the pictures, or both, are capable of the same service, and of other uses. But I shall here dwell only on the more common form of the instrument; because its simplicity gives it a much wider range of application. That instrument is of the most value which can be trusted to the child under the supervision of the parent or caretaker, rather than one to be used for a brief time in the office of the surgeon.

As has been indicated above, these exercises must be practiced a considerable portion of the time to be of great service. The object of the first exercises with the stereoscope is to cultivate the ability to see with both eyes at once. For this purpose a series of pictures is required, the two halves of which differ, but are so related that they may be appropriately superimposed. The picture of the bird presented to one eye, and its cage to the other, is typical of this sort. The stimulus to co-ordinate action is given, when the child is induced to try to get the bird into the cage, or into the center of the cage. Exercises of this character prepare the way for more advanced efforts. They also remain of great use throughout the treatment. Even when normal binocular vision has become habitual, it is worth while to recur to them.

If the child has previously had some practice with fusion tubes, the second class of pictures may soon be brought into use. In these, some portion is common to both pictures. This portion must be fused to avoid diplopia, while the completeness of the picture proves that single vision is not obtained by excluding one eye. Pictures of this sort are less interesting to the child, because their component parts have a single fixed relation; and do not offer the same opportunity of conscious adjustment. On this account one should have a large series of them and should supply them a few at a time. They may be made out of ordinary stereoscope pictures by cutting off different corners from each, or by placing a dot on one, and a cross on the other, and making sure that the whole picture, or both dot and cross are seen.

When binocular fusion is well advanced, the distance between the pictures and the lenses may be varied. If the pictures be wider than the pupillary distance of the patient, variation of the distance from the eye will cause slight variations in the actual amount of convergence. If the width between corresponding points of the pictures equals the pupillary distance, pushing them nearer to or farther from the lenses will make no difference in the convergence required. But it will alter the necessary state of accommodation; and a change of relative accommodation is an exercise of very much the same value as change in relative convergence.

The Reading Bar.—One other practical device remains to be noticed—the reading bar. It provides a highly specialized exercise, depending for its value on the fact that our printing arranges words in long lines, each of which must be followed throughout its whole extent in rapid succession. The bar excludes the habitually seeing eye from seeing some portion of each line, compelling the use of the deviating eye for that part of the time. It has the advantage that it can be employed while pursuing a customary occupation. This is a great advantage within its somewhat narrow sphere of usefulness. I have found it of most value in the preparation of older patients for operation; and in establishing a new co-ordination of eye movements after operation.

Increase in Population in France.—The latest census shows that France has gained 412,364 inhabitants during the last four years. The *Sem. Méd.* adds that this is three times the gain of the preceding four years.

THE STRABISMUS OPERATION.*

C. F. CLARK, M.D.

COLUMBUS, OHIO.

Though a somewhat hackneyed subject, the last word has not yet been spoken upon the strabismus operation, nor will it be for many years to come. While without doubt it is true that excellent results may be obtained in the correction of strabismus by a variety of operative procedures, it is also true, as I think every operator present will acknowledge, that there is a diversity in the results of this operation which plainly indicates that perfection has not yet been obtained. I offer no apology for occupying your time with the consideration of a department of ophthalmic surgery on which such diverse opinions are expressed as we may find in the text-books and articles which appear from time to time on the various phases of this subject.

An analysis of the opinions expressed by a limited number of operators of national and even international reputation will show a divergence of views not only as to details, but on such important points as the following: 1, as to the degree of deviation and the character of the cases which they consider proper subjects for operation; 2, as to the age at which an operation should be performed; 3, as to the choice between tenotomy and advancement; 4, as to the amount of deviation that may be safely corrected by tenotomy; 5, as to whether the operation should be confined to the eye which most constantly deviates or its effect distributed between the two eyes so as to preserve the ocular balance; 6, as to full correction of the error in the first operation or delaying a portion of the operative procedure until the effect of the first division may be properly estimated; 7, as to the practicability of partial, or graduated tenotomy or advancement; 8, as to the value of orthoptic exercises before and after operation; 9, as to the value of tests made with prisms and otherwise during the progress of an operation; 10, as to the importance of the subconjunctival method of Snellen and of suturing the conjunctival wound; 11, as to the necessity of bandaging one or both eyes after an operation for tenotomy or advancement; 12, as to the relative importance of operations upon the superior and inferior recti muscles in cases of hyperphoria and hypertrophia associated with lateral deviations, and 13, as to the most approved form of operation for tenotomy and advancement.

I fully realize that different methods will always have their advocates and it is no part of my intention to undertake to harmonize the views of the members of this Section, but in view of the divergence of theories and methods of procedure which now prevail, is it not proper that each of us should study the plan pursued by his associates and assure himself that he has not been committing that common error of successful surgeons of being too well satisfied with his own methods and results? I am persuaded that when the last word has been spoken on this subject we will have greater consistency in methods and far greater uniformity in results than now prevail.

Dr. Herman Knapp in his excellent chapter on operations,[1] makes the following statements: "1. After a tenotomy of the internal rectus the primary effect is apt to diminish for several days, but then, as a rule, it increases gradually for weeks, months and years. In many cases we rejoice at having obtained a perfect cosmetic result, but when we see our patient again in later years his eyes diverge more or less. 2. The immediate effect of a tenotomy of the external rectus increases the next three or four days, then it diminishes very gradually, so that the ultimate result is frequently not more than two or three millimeters, and at times it disappears altogether."

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

[1] Norris and Oliver's "System of Diseases of the Eye," vol. III.

An over-correction after division of the internal, and an under-correction after division of the external rectus is then of not infrequent occurrence after a tenotomy even when performed by so careful an operator as Dr. Knapp, and I think every operator of wide experience will agree with me that, in spite of the most painstaking observance of every rule which prudence may dictate, in the correction of high degrees of convergence, we are often disappointed in our final results.

In contrast with this note the following statement made by Landolt,[2] who for a number of years past has been advocating the substitution of advancement for tenotomy as a routine measure: "In twenty years' practice we have never had an over-correction after advancement, which is frequent after tenotomy. We have never produced a strabismus, which can hardly be avoided after tenotomy, at least in the secondary position. The advancement has also the cosmetic advantage of not causing annoying protrusion of the eyeball, sinking of the caruncle, or exposure of the sclera."

If one of these plans of procedure is correct the other is certainly questionable, and yet there are many advocates of each. By far the majority seem, at least in their practice, to still prefer tenotomy when it can be made to serve their present purpose. It is more in keeping with our traditions and is less tedious; but it is a significant fact that, while even approximately perfect equilibrium of the ocular muscles after well-marked strabismus is, as we all realize, most difficult of attainment, such a result is claimed in many instances by those who advocate Landolt's method, and are willing to take infinite pains to obtain it.

A few years ago there was, as will be remembered, a strong reaction against those extremists who claimed to be able to work miracles in all nervous diseases by slight-of-hand performances upon the ocular muscles. This reaction was timely and proper, but we should not be led so far in the direction of conservatism as to prevent our accepting and adopting every improvement in method and technique which has a rational basis.

A careful review of the subject and what personal experience I have had in this direction, leads me to make the prediction that within a few years many of those who have heretofore depended mainly upon tenotomy for the correction of strabismus will find themselves adopting the more tedious but far more conservative operation of advancement, or resection almost as a routine practice.

While, for the purposes of this paper, it is not practicable to consider fully the anatomy of the ocular muscles, there are a few practical points which it will be well to review before passing on to the subject of operations. The oculo-orbital fascia, in the descriptions of which great variations are found, should be dealt with as a mass of more or less condensed connective-tissue fibers, differentiated into a dense membrane in certain portions, while in others it is made up of somewhat loose connective tissue joining the conjunctiva to the eyeball and to the sheaths of the tendons of the recti muscles and also uniting the sheaths of these muscles somewhat loosely to the sclera. The lateral or restraining fibers connect the sheaths of the muscles with the more condensed portions known as Tenon's capsule. The effect of this anatomical arrangement is that a division of the tendon at its insertion, provided the lateral fibers remain intact, results in a limited retraction of the tendon and its secondary insertion at a point only a short distance posterior to its former point of union with the sclera. The passing of a hook beneath the tendon and breaking up of the loose fibers which unite its sheath with the sclera, adds very little to this retraction. The division of the fibers which unite the sheath of the muscle with the conjunctiva, adds more to the power of retraction, but if we wish to obtain free retraction of the muscle we must divide the lateral fibers connecting it with the more dense portions of Tenon's capsule which lies between the muscles, or what in fact amounts to the same thing, separate this capsule from the sclera above and below the point of insertion of the tendon. The foundation of all theories which deal with the subject of tenotomy and advancement lies in the relations of the tendons and muscles to this oculo-orbital fascia, or to be more exact, that portion of it which is termed Tenon's capsule. The tendons of the recti muscles are inserted at points varying somewhat in distance from the margin of the cornea: The internal rectus at a distance of 5.5 mm., the inferior 6.5 mm., the external 6.9 mm., and the superior 7.7 mm. The widths of the tendons also differ in the following order: internal 10.3 mm., inferior 9.8 mm., external 9.2 mm., superior 10.6 mm.—Fuchs. In length the tendon of the internal is 8.8 mm., the inferior 5.5 mm., the external 3.7 mm., and the superior 5.8 mm.—Merkel.

It is well in operating to remember also the peculiar insertion of the superior rectus muscle. It is quite wide, and at the nasal side is inserted much farther forward than at the temporal. It is so set that the bulk of its insertion is on the outer half of the eyeball. The inferior rectus on the other hand is so inserted that its temporal border is slightly in advance of the nasal. The measurement (3.7 mm.) given above by Merkel as the average length of the tendon of the external rectus muscle, does not conform to the impression I have obtained in the advancements and tenotomies which I have made.

In a number of resections of this tendon I have removed more than 3.7 mm., and obtained excellent results. It is possible that in doing so I may have included some of the muscular fibers.

For our purpose the various operations resorted to for the correction of strabismus may be classified under the following heads:

Tenotomy.—1. Partial division of the tendon (graduated tenotomy). 2. Complete division of the tendon. 3. Complete division of the tendon, with division of the lateral fibers of the capsule.

Advancement.—1. Partial advancement of the tendon (graduated advancement). 2. Complete advancement of the tendon. 3. Complete advancement of the tendon with advancement of the capsule. 4. Resection of the tendon. 5. Resection of the tendon and capsule.

In all of our operations for the correction of strabismus, the following general rule should be observed and exceptions to it are seldom justifiable: Whether we operate by tenotomy or adopt the more conservative method of advancement, the effect of the operation must be so distributed between the various muscles as to preserve the control of the eye in all ordinary movements.

---

[2] Archives of Ophthalmology, vol. xxvi, p. 8.

A simple tenotomy will, according to Fuchs, correct about 3 or 4 mm. of convergence. In divergent strabismus, he has found that a simple tenotomy will not correct more than 2 mm. as an average. In view of the effects which we have all obtained in some of our earlier operations, this rule seems extremely conservative, but if we confine our division to the tendon at its point of insertion and avoid division of its lateral attachments, I do not believe it is safe to expect a much greater result than he has indicated, and in my own operations where I have depended upon tenotomy, I have seldom gone far beyond this limit without having reason to regret it.

Many rules have been laid down to enable the operator to avoid the excessive effects which often follow as a late result of tenotomy, but in difficult cases it not infrequently happens that, in order to obtain even a moderate degree of correction, these rules are violated. When more than 3 mm. of convergence, or 2 mm. of divergence is present, if tenotomy is relied upon, the effect should be divided between the two eyes rather than by operating upon one alone to obtain a correction at the expense of a free division of the lateral attachments.

Knapp lays down the following rules to govern the operator in tenotomy: "A. As a rule no squint operation should weaken the muscle beyond its physiological limit of power. B. After a tenotomy of the internal rectus, the result of the immediate examination should be as follows: 1. In adduction the medial margin of the cornea should readily reach the caruncle. 2. The near point of binocular fixation should not be less than 5 centimeters—two and one-half inches. 3. The eyeball should not protrude. 4. There should be some convergence left."

If these rules are strictly adhered to and the lateral fibers are left undisturbed, we may undoubtedly avoid an—immediate—over-correction, but the weak point in such a system of rules is that, if strictly adhered to, only a slight correction of 3 or 4 mm. is obtained and, even if the operation is divided between the two eyes, a careful examination of the field of fixation will almost certainly reveal some limitation of motion.

How often it has happened in the experience of each of us that after such a tenotomy the immediate result has been not only insufficient but almost nil and to save ourselves and the patient from the chagrin of a sense of failure, we have divided first a few and then a few more of the lateral fibers and then wondered whether we would not at some future time discover that we had slightly over-corrected the error.

Now it is a fact that even the setting back of the tendon alone, if it is sufficient to give us 3 or 4 mm. of correction must, to a limited degree, restrict motion and violate the spirit of the first of these general rules.

The very essence of such an operation consists in the fact that the control which the muscle exercises over the eye is made less effective, whereas it should be our object not to lessen but to increase this control. The movement of an eye, in a given direction, depends not alone upon the contraction of the single muscle which turns it in that direction but also, and only to a less degree, upon the co-ordinated movement of its antagonist, while both of these must again act in harmony with the corresponding muscles of the other eye. In any squint not dependent upon paralysis or traumatism, surgical or otherwise, of one of the muscles the squinting eye, while having an improper direction, still moves in harmony with its fellow and its excursions are usually of the same amplitude. If we wish to preserve the harmonious relation of the four muscles which take part in this somewhat complicated act of co-ordination is it reasonable to begin by an avowed attempt to cripple one of them?

It is a mistake, as Landolt has pointed out, to suppose that the antagonist gains in strength what the tenotomized muscle loses and, even if it did, it is not proven that the muscle we divide has more strength or more power to move the eye than it should have. It is a question not of power but of direction with which we are dealing and the choice between tenotomy and advancement reduces itself to this: Is it better that the group of four muscles acting to produce harmonious movements of the two eyes, should have the aggregate of control which they exercise over the eyes increased by giving one of its members a more advantageous attachment, or diminished by setting another back and thereby lessening its control?

In the latter case we gain the proper direction, but in so doing we make a distinct sacrifice of a portion of the control which the group exercised over the eye, while in the former we also gain the proper direction but increase the aggregate of control by giving to one of the members an advantage in moving the eye which may be exercised or not as circumstances may demand.

I do not wish to be understood as advocating so radical a change in the accepted method of dealing with squint as the entire substitution of advancement for tenotomy, though that would seem to be the logical outcome of the above reasoning.

Advancement is so tedious and tenotomy so simple an operation that the latter will probably always be preferred in slight deviations, but whenever a deviation exceeds 5 mm. it is proper to raise the question whether an advancement should not be substituted for tenotomy; and whenever in any case of tenotomy it is found that the proper effect can not be produced without considerable division of the lateral attachments of the tendons an advancement should be substituted or should supplement the tenotomy.

As to the best method of performing a tenotomy or advancement, it is my opinion that equally good results may be obtained in a variety of ways, provided certain general principles are observed, and it is with general principles that we are here dealing rather than with the details of special methods of operating. these principles the most important relates to the division of the effect between the various muscles and the preservation of as complete control of the eye by each muscle as may be practicable. If the deviation is slight and a tenotomy is decided upon I greatly prefer the method of Snellen as modified by Stevens—a sub-conjunctival operation—buttonholing the conjunctiva and tendon and cutting both ways. But in those relatively frequent cases in which, after the first incision, there is well-marked hemorrhage beneath the conjunctiva, I at once convert the small incision into a large open wound in order to avoid a troublesome sub-conjunctival thrombus.

Careful measurements, linear, angular and by prisms, before, during and after the operation, I consider of the utmost importance, but in cases in which there is marked amblyopia we must judge mainly by inspection and for this purpose there is a great advantage in operating in a dental or other reclining chair and in having the patient in the upright position while testing so that the operator may stand off at a distance of eight or ten feet and observe the movements of the eyes. An examination made at the near point is often very misleading. If the operation is divided between the various muscles of the affected group and, in case the deviation is marked, is corrected mainly by a well-performed advancement or resection, measurements are of great value, but in the old method of operating in which the tendon was divided at one cut and what deviation remained was corrected by free division of the lateral attachments, the eye became so unstable that measurements made at the time of operation afforded very little information as to what the final position of the eyes would be.

It is not infrequently the case after a carefully performed operation for convergent strabismus as a result of which the eyes occupy approximately the proper position, to have, owing to the presence of what is sometimes termed a false macula, a well-marked heteronymous diplopia with the images widely separated.

This is probably due to what Dr. Berens has well termed "neuro-muscular memory," and should not disconcert us as it seldom causes serious disturbance, though it may make it more difficult to judge of the accuracy of the result obtained. We are, in fact, forced in such cases to depend entirely upon objective tests. It must, of course, be borne in mind that the more extensive the traumatism inflicted during the operation the more unreliable are the results of measurements made immediately after operating, and this is an additional argument in favor of advancement in its various forms, as by this means we seldom have an over-correction and by allowing a portion of the deviation to remain, we may at a subsequent operation gauge the result accurately in a supplemental tenotomy, correcting the slight remaining defect.

In tenotomy we should, so far as may be practicable, let the capsular attachments alone if we wish to avoid crippling the combined movements of the eyes, but in advancement or resection it is desirable, in our attempts to increase the control exercised by a given muscle, to bring forward or shorten the capsule with the tendon. In so doing we gain another advantage which is of great importance, in obtaining a firm hold for our sutures. In fact, in the resections which I have performed of late, I have made free use of sutures, practically quilting the tendon and capsule together, and have thus avoided a very annoying feature of some of my former advancements in which the effect would be in part lost within a few days owing to the insufficient and uncertain hold obtained by sutures introduced in the usual manner in the tendon alone.

While it has been greatly improved within a few years, there is room for still greater improvement in the operation for advancement. Before the days of asepsis advancement was indeed a formidable operation, often being followed by decided reaction, and even as now practiced when we compare it with tenotomy it is not strange that a beginner in ophthalmic surgery should, when in doubt, prefer the latter. But the question of a little more or less annoying detail in the operation should not be allowed to weigh against any advantage we may gain for our patients, and advancement should be unhesitatingly performed when it is apparent that it will produce a better final result.

The old operation, by which the tendon is split in its center and one portion drawn forward above and the other below the cornea, while certainly effective, has seemed to the writer unnecessarily complicated. Any method which, with a freely exposed field of operation, succeeds in securing and evenly mooring the tendon and capsule of Tenon to the sclera at a point well in advance of its former point of attachment will accomplish the desired end and, in cases of less marked deviation, a method which resects a sufficient amount of the tendon and capsule and firmly sutures the distal to the proximal portion will also yield an excellent result.

Because of the thorough manner in which the field of operation is exposed, probably no method is a greater favorite with those who have tried it than that devised by Dr. Savage of Nashville, by which an L-shaped primary incision is made, one side of which is parallel with the line of insertion, and the other parallel with one border of the tendon and the flap turned well back and held out of the way by a suture while the tendon is advanced or resected.

The method of capsular advancement advocated by Dr. Fox of Philadelphia for cases in which there is extreme deviation certainly has the advantage of simplicity and the results he reported to this Section last year were excellent, but I have been thus far deterred from adopting it owing to the amount of traumatism inflicted and a feeling that I would prefer to see the tissue with which I am dealing in an operation of such delicacy.

With the exception of those cases in which the degree of deviation is excessive, resection affords excellent results and for several years I have been endeavoring to discover some method by which I could simplify the ordinary procedure and substitute it, so far as is practicable, for tenotomy. I found that by introducing a tenotomy hook in the ordinary manner and then seizing the fold of tendon beneath the hook with Prince's advancement forceps, I could gauge the amount of tendon removed by the point at which the forceps' blades were applied and suture it thoroughly and evenly at my leisure.

This led me to devise the small double hook which is figured in the report of this Section for last year and which in a number of instances has since served an excellent purpose.

After making a vertical conjunctival incision as long as, and one or two millimeters behind the insertion of the tendon, I make in Tenon's capsule two short cuts with the scissors parallel with and a short distance above and below the tendon and extending from its point of insertion backward to a distance equal to the amount of shortening desired. The central blade of the hook is now inserted below and made to include the tendon and that portion of Tenon's capsule which covers it and by turning the milled head this central hook with the tendon and overlying capsule is drawn up between the other two blades to such a distance as may be desired. Interwoven sutures are then inserted, firmly stitching the two surfaces of the folded tendon together, after which the hook is removed, the apex of the fold cut away with the scissors and the conjunctival wound closed with fine silk sutures.

A comparison of the writings of various acknowledged authorities on strabismus reveals in the after-treatment the same diversity of opinion as is observed in other departments of this subject. While Dr. Duane of New York prefers after tenotomy to keep the eyes open and practice orthoptic exercises before the wound is firmly united in order to obtain binocular fixation, Dr. Landolt, on the other hand, keeps both eyes bandaged during the healing process, often insisting upon the patient remaining in bed for six days. Between these extremes we may find every variety of directions given to patients as to their conduct after operation, which only proves that, as in other departments of surgery, fair results may be obtained in a variety of ways. And, while I have obtained good results by the course I have pursued, which may be said to be midway between these extremes, I am free to admit that it would give me the greatest pleasure to be able to observe minutely the progress from day to day of the patients treated by both the methods described, as certainly Dr. Landolt's reports indicate a higher standard of final results than is claimed by many operators, and under such circumstances it is becoming that we should at least hold our minds open to conviction.

In conclusion, I would state as my conviction that, in the correction of strabismus, advancement, or resection combined with a very limited tenotomy, should, as a rule, be substituted for simple tenotomy.

ARTIFICIALLY PREPARED FOODS, THEIR NUTRITIVE VALUE AND DIETETIC APPLICATION.

L. BREISACHER, M.D.
Consulting Gastro-enterologist, Harper Hospital; Formerly Professor of Comparative Physiology, University of Pennsylvania; Member of American Physiological Society.
DETROIT, MICH.

The history of the scientific production of artificially prepared foods, like that of the subjects of digestion, nutrition and metabolism, is nothing more than a summary of the achievements of the experimental sciences relating to general biology and the science of medicine.

Investigation of the various empiric dietetic systems, from the time of Aristotle up to the end of the eighteenth and the beginning of the nineteenth century, shows that, while various grain decoctions, ptisan, almond, egg and sugar-water and probably a few other dietetic preparations were used for invalids, no preparation existed which might lay claim to being an artificially prepared food in the sense that the term is used to-day. Far reaching and revolutionary were the discoveries which ushered in the birth of the exact knowledge of nutrition and dietetics![1] On the one hand we had the discovery of oxygen by Priestly and Scheele in 1774, and the subsequent development of the theory of oxidation by Lavoisier in 1780; on the other hand was the investigation of Spallanzani and Reaumer, in 1752, on the subject of digestion.

Let us here rapidly sketch the outlines of the growth of our subject and review the fundamental principles by which the nutritive value of foods may be judged and the nutritive demands of the human individual adjusted. In this manner we shall be able to appreciate the status of our subject and to determine the applicability of artificially prepared foods to the diet of man in health and disease.

Although from the time when Lavoisier defined the processes of oxidation, up to, and even beyond, the first quarter of the nineteenth century, considerable work had been done on the subject of nutrition, little was really accomplished until the theories of Liebig, the greatest chemist of that century, were shown to be incorrect. As late as 1842 very little was known of the nutritive and physiologic significance of albumin, fat and carbohydrates. It was during this period that Liebig believed that the destruction of albumin served the purpose of furnishing the organism with energy for the execution of mechanical work, while the oxidation of fats and carbohydrates was supposed to furnish heat to the body and protect the albumin from unnecessary oxidation. It was very soon shown, however, that this explanation was incorrect, for experimental evidence was brought forward which proved that the increased ingestion of albumin by an animal at rest was accompanied by a corresponding increase of nitrogen excretion. Important as was the demonstration of this fact, its exact significance was unfortunately misconstrued, and, in consequence, gave rise to much controversy and years of laborious experimentation. It was now taught that the minimum quantity of albumin necessary to the animal organism was expressed by the quantity of albumin disintegrated during inanition. Finally, during the years 1857-60, Bischoff, Voit and Pettenkofer published the results of their experimental work, and it was at this time really that the cornerstone of nutrition, as an exact science, was laid.

For the continued normal expressions of the functions of an organism, the ingestion of a certain and definite quantity of food is requisite. This general biologic law manifests itself, irrespective of theoretical speculation or scientific observation, in the expression of the instinctive impulse which guides every organic entity in its selection of the requisite quantity and quality of food. However, not until Helmholtz and Meyer formulated the theory of the conservation of energy, did we fully appreciate the philosophy of this law.

Every organic function is accompanied by the production of heat, which finds its origin in the oxidation of definite chemical combinations, the absorbed and assimilated products resulting from the digestion of substances termed foodstuffs. The amount of heat which an organism gives off is equivalent to the calorimetric value of the food which it requires in a given period of time. The food which the system requires is represented by the nutrient principles, albumin, carbohydrates and fat, each one of which may substitute or replace the other, but only, as we shall point out later, within the limit of their minimum nutritive or physiologic quantity. Irrespective of the relative proportions of each one of these food principles, the total heat requirement of the organism remains the same.

Every foodstuff possesses a certain caloric value, which is expressed by the term calorie, and each represents that quantity of heat necessary to raise one kilogram of water from 0 to 1 C. It is customary to express the total quantity of nutriment necessary to maintain the nutritive demands of an organism by the caloric value of the food introduced into the system. Instead of simply stating that the system requires so much each of fat, albumin and carbohydrates, we express it by the number of calories which the system requires in a given period of time under definite circumstances, presupposing always that these three foodstuffs be contained in certain proportions and in definite relationship to each other. Although this is a very convenient method and the one now generally followed, it is not strictly logical, because it neither embraces the valuation of the nutriment required to rebuild the wasted tissue of the body, nor, in the organism at rest, the amount of energy expended in the carrying on of circulation, heart beat, respiration, gastro-intestinal and glandular activity.

Expressing, therefore, only partly the metabolic significance of a given food, the caloric method is, nevertheless, the most convenient we have at our disposal at the present time. This method is founded upon the fact, to which we have already alluded, that the amount of heat given off by an organism is practically equivalent to the calorimetric value of the food which has been introduced into it. When fat, albumin, carbohydrates or gelatin is subjected to calorimetric estimation it is found that each has a definite caloric value, thus one gram each of these foods equals the following: Albumin, 5.7 calories; gelatin, 5.5; fat, 9.3; starch, 4.1; cane sugar, 4.0, and glucose, 3.7 calories.

---

[1] Breisacher: The Principles of Metabolism and Nutrition.

The method of calorimetric estimation of foodstuffs consists in introducing a given quantity of food material into a specially constructed bomb, which is filled with oxygen under a pressure of from fifteen to twenty-five atmospheres. After the bomb has been submerged in water, the substance under examination is ignited by means of electricity and an estimation made of the heat imparted to the water.

It has been shown that fats and carbohydrates when introduced into the system are oxidized into carbonic acid gas and water, and further, that when subjected to the action of a calorimeter they undergo a like change. With albumins, however, the matter is somewhat more complicated, for, while they are oxidized into nitrogen, carbonic acid gas, water and a small quantity of sulphuric acid in the calorimeter, in the animal organism they are split up into urea, uric acid, kreatin, kreatinin, hippuric acid, etc. To determine, therefore, the caloric value of albumin to the system it is necessary to subtract the caloric value of these organic oxidation products.

By this method of calculation we find that the physiologic nutritive value of albumin is 4.1, compared with its calorimetric value of 5.7. The physiologic heat or caloric value of fat and carbohydrates is identical with the calorimetric value. The physiologic or nutritive caloric value, therefore, of one gram of fat is 9.3, of one gram of carbohydrates, 4.1, and of one gram of albumin it is also 4.1. Fat, albumin and carbohydrates form the three chief nutrient principles which enter into the diet of a human individual. The necessary quantity of each one of these separate nutrient principles required by the system, and the relationship of one to the other, is dependent upon varying circumstances. The relationship of fat, carbohydrates and albumin in the diet of an infant is not identical with that in the diet of an adult, neither is the required relative quantity of these nutrient principles, estimated per kilogram body weight, the same in the mature as in the immature organism. Further, the demands of a weakly developed inactive organism are different from those of a laborer or an athlete. In accordance with the law of substitution, each nutrient principle may be substituted for the other, within its minimum physiologic limit, as recent experiments have conclusively shown.[2]

A thorough comprehension of these laws, which I shall define more particularly later on, is absolutely necessary in the rational feeding of both healthy individuals and invalids. The fundamental principles, upon which our entire knowledge of the subject of nutrition is founded, are the result of experiments made upon human individuals and animals. Among the most important are those experiments made upon fasting individuals. When food is absolutely withheld from a man weighing about 70 kilograms—154 pounds—for a period lasting from twenty-four hours to a number of weeks, it is found that the system loses from 50 to 80 grams of albumin and from 200 to 250 grams of fat, each day. In a single twenty-four-hour period the loss of water is from 800 to 1000 c. cm.; in longer periods, the subject of the experiment is usually given a sufficient amount of water to cover this loss.

The execution of a certain amount of mechanical labor during a period of fasting increases the fat consumption and water exhalation while the albumin waste remains the same as in the fasting individual at rest. It has further been shown that persons provided with an abundant supply of adipose tissue withstand the influence of fasting more effectually than lean individuals, for the reason that in the former the adipose tissue furnishes the major percentage of caloric demand of the organism, thus protecting the albumin supply from excessive waste.

The size or bulk of an individual also determines the total fat and albumin consumption of the system, and it has been demonstrated that, while the absolute quantity of albumin and fat may be greater in the larger individual than in the smaller one, the relative quantity of both of these foodstuffs, estimated per kilogram body weight, is greatly in excess in the smaller or less bulky individual, than in the larger one. This law is equally invariable, irrespective of whether the food consumption refers to a fasting or normally fed individual, or whether it be applied to an infant or an abnormally large or small adult. The nutritive demand per kilogram body weight, therefore, is in an inverse proportion to the size or bulk of the organism.

If an animal from which food has been withheld for a certain period of time, i. e., a number of days or weeks, be fed meat it will be found that the nitrogen excretion, as expressed by the nitrogen in the urine, is increased, and, with each additional increase of albumin (meat) to the diet, the excretion of nitrogen is increased proportionately. This increase of nitrogen excretion continues until sufficient amount of albumin (meat) has been added to the diet to effect a nitrogen balance, that is, a nutritive condition in which the nitrogen income is equal to the nitrogen outgo. It was taught by Voit that the quantity of albumin necessary to cover the albumin loss of the system was two and one-half times greater than the loss resulting during a period of fasting. This, however, is not strictly correct, as the writer and several other investigators showed in a series of nutrition experiments.[3]

In addition to the loss of albumin, the fasting individual suffers a distinct loss of fat from his organism, and it has been found that, by insuring the absorption of fat equivalent to the loss of adipose tissue during fasting, the fat consumption may be checked while the albumin destruction remains unchanged. It follows from this that the ingestion of fat by a fasting animal may prolong life, but not prevent ultimate death from starvation. The exclusive feeding of carbohydrates, like that of fat, does not prevent the occurrence of death by starvation, although they protect the system from albumin destruction more effectually than fat.

If a definite quantity of fat and albumin is given to an individual who has been subjected to a period of fasting, it will be noticed that the loss of organic or body albumin is arrested. This does not occur when simply fat or carbohydrates are given and which can not be practically achieved in the human being by an exclusively albumin diet. Fat, whether existing in the system as adipose tissue or introduced into the system as food, protects the organic albumin from undue waste.

---

[2] Breisacher: (a). Eiweissbedarf beim Menschen; (b). Principles of Metabolism and Nutrition.

[3] Breisacher: Eiweissbedarf beim Menschen.

When along with a requisite amount of albumin, more fat is introduced into the system than the total caloric demand requires, an increase in the supply of adipose tissue is achieved. When carbohydrates, in the form of sugar, starch or dextrin, are added to a diet composed simply of albumin, the destruction of the latter is lessened, and, as in the case of fat and albumin, if a sufficient quantity of carbohydrates be added to a requisite amount of albumin, the loss of organic albumin is arrested. Likewise, when carbohydrates are added to a combined fat and albumin diet, the total consumption of both of the latter is lessened. The effect, however, of like quantities each of fats and carbohydrates, in retarding albumin consumption, is not identical. Notwithstanding the fact that a gram of fat represents a caloric value, which is 5.2 greater than a gram of carbohydrates, it has less influence in checking albumin waste than the latter. As we have already pointed out, when an excess of fat is fed to an individual, a deposit of fat, in the form of adipose tissue, is effected; when an excess of carbohydrates is fed, an elaboration of fat, with a resulting increase of adipose tissue, takes place.

Gelatin is a nitrogenous substance resembling albumin in its atomic arrangement, in its conversion into peptone by the gastric and pancreatic secretions, and in its final oxidation into urea. When gelatin is added to an albumin diet, it has an influence in lessening organic albumin and fat dissipation similar to that possessed by both fat and carbohydrates. It is of interest to note that while gelatin has a more pronounced effect in lessening organic albumin destruction than both fats and carbohydrates, in reducing the organic fat dissipation it is less effectual than either fat or carbohydrates. Despite the chemical resemblance of gelatin to albumin it can not replace that substance, nor are we acquainted with any substance which can substitute the minimum physiologic nutritive quantity of albumin necessary to an animal organism.

These then are, in brief, the primary fundamental principles by which we must be guided in nourishing individuals, both in health and in disease. These principles emphasize the fact that of the three chief nutrients—albumin, fat and carbohydrates, to which a fourth, gelatin, may be added—albumin is the substance which requires the foremost consideration in the selection of a diet. This is true because it can not be replaced by any other known nutrient, irrespective of whether it belongs to the nitrogenous or non-nitrogenous group of chemicals or foodstuffs.

These principles further teach us that one or preferably both of the non-nitrogenous food principles, carbohydrates and fats, *should be added to an albumin diet* for the maintenance of the healthy functions of the organism. To these two *non-nitrogenous* nutrients we may add gelatin, which, as we have seen, has an influence similar to that of both fat and carbohydrates.

Let us here consider the exact quantity in which each one of these nutrient principles must be contained in the daily diet, and the circumstances which determine a variation in the quantitative demands of the system upon these substances. The nutritive demands of the human organism, from the period of infancy to that of adolescence and from the latter to that of maturity and decline, are subject to varying *fluctuations*. Again, different degrees of bodily activity, both physical and psychical, during sleep and the *waking* state, thermic and climatic influences, body weight and size, and finally various *pathologic conditions, all make* definite nutritive demands upon the system. For instance, in infancy there is *more nutriment required*, estimated per kilogram body weight, than during the period of maturity; the body weight and size has an *influence*, as we have already pointed out, in so far that a smaller organism requires relatively more *nutriment than* a larger one; during sleep or absolute rest, compared with the waking state, the albumin *metabolism remains unchanged*, while the fat and carbohydrate consumption is reduced; bodily exercise is accompanied by an increased carbohydrate and fat consumption, while the albumin metabolism remains uninfluenced. *Heat and cold affect* the organism differently—increased body temperature raises the total carbohydrate and fat *consumption, while the reduction* of external temperature increases, and an increase of external temperature reduces, both the *fat and carbohydrate* metabolism.

Finally, *in pathologic conditions*, such as fever, dyspnea, anemia, diabetes, Bright's disease, icterus uric acid diathesis, etc., various *nutritive* abnormalities are discernible, and it behooves us at this point to determine the *normal nutritive mean of the* organism and its practical application to pathologic conditions. In this way we *shall be enabled to logically appreciate* the dietetic demands in pathologic conditions and estimate the applicability *of artificially digested foods to the dietary* of invalids. We indicated in our foregoing remarks *that the preferable diet for a normal individual is* one consisting of certain quantities of albumin, fat and *carbohydrates*.

Determined by methods which consisted in estimating the *nitrogen and carbon output in individuals subsisting* upon an ordinary indefinite diet, it was originally estimated that the average individual of 70 kilograms—154 pounds—body weight, at rest and during moderate and severe physical labor requires for every twenty-four hours, 100 to 140 grams of albumin, 50 to 100 grams of fat and 400 to 500 grams of carbohydrates. Practical observation has shown that some individuals subsist upon as little as 75 to 80 grams of albumin in twenty-four hours, and experimentally these figures can be materially reduced for a considerable length of time, as the writer showed in a series of experiments covering a period of 33 days.[3] In ordinary cases, however, unless prompted by some particular reason to materially reduce the albumin quantity, it will be preferable to adhere to the 90 to 100 grams of albumin ration for the average individual at rest or during light exercise. Figured in calories, the average individual requires during absolute rest from 30 to 34 calories per kilogram body weight, during light exercise 34 to 40, for a medium amount of work 40 to 45, and during severe labor 45 to 60 per kilogram body weight, for every twenty-four hours.

A diet consisting of 100 grams of albumin, 50 grams of fat and 400 grams of carbohydrates would equal: Albumin 100 grams $\times$ 4.1 $=$ 410 calories; fat 50 grams $\times$ 9.3 $=$ 465 calories; carbohydrates 400 grams $\times$ 4.1 $=$ 1640 calories—a total of 2515 calories. This number of calories represents a sufficient amount of heat or food, for an individual weighing about 74 kilograms, or 163 pounds, at rest. To further elucidate this method of estimation I append a diet list, which I used in a series of experiments made upon myself[2].

Materials.	Quantity	Albumin. (Nitrogen 6.25.)	Carbohydrates.	Fat.
Meat	75 grams	15.40	....	1.33
Rice	200 "	12.36	149.60	0.66
Potatoes	225 "	5.49	45.00	....
Bread	200 "	17.92	120.00	....

Materials.	Quantity	Albumin. (Nitrogen 6.25)	Carbohydrates.	Fat.
Starch	70 grams.	0.28	69.72	....
Eggs	50 "	6.27	....	6.05
Milk	150 "	5.60	7.39	6.75
Sugar	40 "	....	40.00	....
Butter	50 "	0.43	....	....
Beer	700 "	3.67	62.51	....
Tea	760 "	0.58	....	....
		67.80	494.22	60.49

Albumin 67.80 × 4.1 = 277.98 calories; carbohydrates 494.22 × 4.1 = 20.26 calories; fats 60.49 × 9.3 = 562.56 calories—a total of 2866.84 calories.

In the foregoing table the quantity of fat, albumin and carbohydrates is accurately accounted for as is also the total caloric value. The number of heat units, 50.22 per kilogram body weight, is greater than was really necessary, but I chose this number for the reason that I was reducing my albumin ration far below the usual quantity, as I determined by a great number of total nitrogen estimations while on an indefinte diet.

ARTIFICIALLY PREPARED OR PREDIGESTED FOODS.

This brings us then to the actual consideration of the subject of artificially digested foods, and their application to the diet of invalids.

Until 1843, when Graves published his observations upon the diet of fever patients, there existed a dictum in the practice of medicine, which read, that to successfully treat fever patients the diet must needs be reduced to a minimum quantity, and this was successfully accomplished by resorting to cereal water and various broths, which were practically destitute of nutritive value. Following the writings of Graves, in which it was urged that "fevers be fed," the observations of Chossat on the effect of inanition were published, and these two writings then, in conjunction with the experimental observations of Liebig, Voit, Pettenkofer, et al, acted as an incentive to the research upon which our present knowledge of invalid feeding is founded.

Although as early as 1752 Reaumer and Spallanzani discovered the digestive action of gastric juice, it was not until 1824 that Prout discovered the gastric hydrochloric acid, and 1850 that Lehman first applied the term of peptone to the products of albumin digestion. The diastatic action of saliva was not discovered until 1831, although Payen had discovered grain diastase thirty-six years previous to this time.

We have evidence that in ancient times grain water was added to milk to render it more easily digested, and other methods were resorted to in attempting to make food more acceptable to invalids, yet the first important attempt to produce artificially prepared foods was made subsequent to the discoveries which we summarized in the preceding pages. As in other matters pertaining to nutrition, Liebig was a pioneer in the department of artificially prepared foods. Liebig's efforts resulted in the production of these two foods which bear his name: 1, Liebig's extract of beef,[4] known, we dare say, to every civilized race; 2, Liebig's infant soup, which while it is remembered by but few to-day nevertheless deserves the distinction of being the preparation which has given rise to the almost countless numbers of so-called baby foods.

When one considers the havoc which many of these improperly prepared invalid and baby foods have occasioned and the misuse to which numerous really praiseworthy preparations have been subjected, the thought involuntarily arises as to whether it would not perhaps have been far better had the idea of artificially preparing foods for invalids and babies never occurred to any one. The subject of the feeding of artificially prepared foods is in the same deplorable condition as that of nutrition in general, but whereas ignorance and neglect of the subject of nutrition, as applied to feeding the average individual and using the term in a general sense, affects simply healthy or somewhat indisposed individuals, lack of proper knowledge to correctly adjust the administrations of artificially prepared foods affects both the helpless infant and the invalid, who really are in need of proper nourishment.

The medical world is justified in insisting that the manufacturer produce an artificially prepared food which answers the requirements of the nutritive demands of invalids. Further, the manufacturer should be compelled to print upon the package of each preparation of artificially prepared food an exact quantitative and qualitative analysis. This is a duty which the manufacturer owes to the medical world, and the duty which the latter owes to the manufacturer is that it sufficiently comprehend the principles of nutrition, thereby insuring the rational application of reliable preparations to the dietary of invalids. With these points observed it simply remains to be determined, in selecting an artificially prepared food, whether it be palatable to the patient and whether it possess the nutritive and therapeutic value required of it.

In selecting an artificially prepared food for an invalid, we are guided by the same principles of nutrition and metabolism as in feeding an individual in health. An invalid, like a healthy individual, requires a definite quantity each of albumin, fat and carbohydrates to furnish the necessary total caloric demand of the organism. We find a deviation from the above statement in certain pathologic conditions, in which it is necessary to reduce the quantity of one nutrient principle and substitute in its place another. I have reference to the reduction or entire withdrawal of carbohydrates in diabetes, the reduction of albumin in uric acid diathesis, etc. Irrespective of a reduction of particular food principles, the total caloric supply must remain unaltered or at least as little changed as is compatible with the condition of the patient. The dream of the medical profession, from the very dawn of the science of nutrition, has been to prepare an artificially digested food which would relieve the gastro-intestinal tract of its usual digestive labor, but, like the illusion of an elixir of everlasting youth, it has resulted only in idle and futile search.

With the newly acquired knowledge of some of the more pronounced phases of digestion, it is comprehensible why the trend of scientific aim should have led experimenters and clinicians in this direction. The artificial conversion of albumin, fat and carbohydrates into their respective end products has, it is true, been accomplished, but, despite this, the subject of the feeding of artificially digested foods is still far from being solved. While the artificial preparation and dietetic application of fats and carbohydrates have given fairly satisfactory results, the same can not be said of predigested albumin, since peptones and albumoses have proved to be stubborn and unyielding in the extreme.

It is not so many years ago that Voit, along with Bruecke and other celebrated physiologists, supported the old view of Tiedeman and Gmelin, according to which peptone was considered to be a decomposition product and one that could not be regenerated into albumin. It was thought that the peptone resulting from the digestion of albumin in the gastro-intestinal tract was absorbed by the circulation as such, and was oxidized in the system in a similar manner to carbohydrates and fats, while the albumin necessary to rebuild the wasted tissues of the organism was thought to be dependent upon the absorption of unaltered albumin from the gastro-intestinal tract. Lehman, on the other hand, contended that the conversion of albumin into peptone was a definite physiologic process, which served the purpose of rendering the latter more easily absorbed, to again be converted into albumin in the circulation. The great authority of Bruecke, however, had its influence, and as late as 1877 peptone was looked upon as being a product of decomposition. Further exact experimental research has indeed proved that many albumins, such as serum albumin, egg albumin, acid albumin and globulin, may reach the circulation without first undergoing peptonization, but it has also been demonstrated that the end products of albumin digestion, instead of being products of decomposition, are reconverted into albumin in the mucous membrane of the gastro-intestinal tract to circulate as such in the system, which fact definitely disposes of the older contention of Voit, Bruecke and others. Two or three years previous to this period the first peptone feeding experiments were instituted, and, while the results of several experimenters made it appear very probable that peptone, so-called, did possess nutritive worth, the proof was not sufficiently conclusive to prevent Voit, as late as 1881, from offering experimental data in support of his earlier contention. Up to this time peptone was considered a simple or elementary compound, but the famous investigations of Kuehne and Chittenden and other of his pupils proved that peptone was really a mixture of many different substances and that the so-called peptone—preparations of manufacturers—consisted principally of albumoses, bodies intermediate between albumin and true peptone.

---

[4] Proust as early as 1821 produced meat extract, but the credit of the practical manufacturer of it really belongs to Liebig.

Several experiments instituted with albumoses and pure peptone apparently proved that the former could serve as a substitute for albumin, while peptone usually acted as a violent irritant, causing vomition and diarrhea. Following these preliminary observations it was then finally proved that a number of preparations, consisting chiefly of albumoses, together with varying quantities of true peptone and insoluble albumin, could be substituted for the ordinary unaltered albumin, such as is contained in the daily food ration. Still more convincing and decisive are the experiments made with pure albumoses, which prove that their nutritive worth is equivalent to unaltered albumin, while anti-peptone, resulting from pancreas digestion at least, seems to be destitute of this power of substitution.

With this problem of the nutritive role of peptone and albumoses fairly well decided, the question arises whether artificially digested albumin is really applicable to the diet of invalids. We have seen that true peptones have not given satisfactory results as dietetic reagents, and, if we bear in mind the comparatively recent discovery that true peptones are formed only in very small quantities in the stomach and that albumoses very likely represent the digestive products which enter the circulation, it becomes evident why concentrated quantities of peptone disagree with patients in the manner noted above. Dismissing, therefore, the idea of utilizing pure peptone as a dietetic agent, and recognizing the clinical and experimental evidence of the nutritive worth of albumoses, we must further ask ourselves what advantage we hope to obtain and what effect we really produce by the feeding of artificially digested albumin. To begin with, most of these preparations have rather a disagreeable taste, which is a disadvantage in a food, making the addition of either meat extract or some other taste-disguising agent necessary. Further, contrary to the general belief, predigested albumin does not possess a higher nutritive worth than ordinary native albumin.

A claim which is often emphasized by manufacturers and accepted by many as being true, is that artificially digested albumin is more easily absorbed than native albumin. But here also abundant experimental and clinical data disprove these claims. The worth of an artificially digested food like that of an ordinary foodstuff is estimated by the manner and degree in which it is utilized in the gastro-intestinal tract.

Let us begin with the stomach. We are in possession of data which prove that the rate of peptone absorption from the stomach is extremely slow and considerably slower than either alcohol or the different forms of sugar. Further, it has been shown that a solution of artificially digested albumin is not absorbed more rapidly from the stomach than a nutritive equivalent of powdered meat measured in calories. The absorptive maximum of the stomach, as one would expect, bears a relation to its degree of digestive activity, and, beyond this degree, the absorption can not be forced. In regard to the intestinal absorption of artificially digested albumin, our experience is as unsatisfactory as in regard to the gastric absorption. Ellinger, for instance, has shown in some comparative tests with meat and somatose that, when each was separately given in quantities representing 8.92 grams of nitrogen, with meat the excreta contained but one gram of nitrogen, while with somatose they contained 10.6 grams of nitrogen. By still another method, that of estimating the degree of intestinal decomposition as expressed by the urinary sulphuric acids, it has been shown that somatose, a representative artificial albumin product, possesses no advantage as a nutrient over native albumin.

It will be seen, therefore, that the supposition that peptones and albumoses are more readily and more perfectly utilized than native albumin does not bear the test of careful investigation. Closely linked to this idea is the supposition that predigested albumin taxes the digestive functions less severely than unaltered albumin. This, like the other statements, is erroneous, for it is clear that the expenditure of energy lies in the secretion of the digestive fluid, not in the digestion of food after the digestive fluid has been secreted.

One might be led to contend that artificially digested albumin does not excite the glandular activity to the same degree as does native albumin. But here again we are confronted with investigations which show that the gastric acid secretions, as determined by exact chemical analysis, may be as great as and even much greater in the case of albumoses and peptones than in the case of unaltered or native albumin.

The second pronounced expenditure of energy of the digestive organs, that of motility, by which food is propelled onward from the stomach into the intestines, is as great, as we have already seen, in the case of predigested as in the case of native albumin. In particular pathologic conditions of the gastro-intestinal tract the results of the application of artificially digested albumin are not materially different from those which have been already mentioned. If we group the distinctive chemical features of the stomach cases, we find that in one class we may have an absolute absence of acid, and in another class a normal or excessive quantity of acid. Between these two extremes we find cases with varying degrees of acidity, which we need not here define more particularly. In addition to the acidity of the stomach, the motility is of the greatest importance, for it is this muscular mechanism which determines the onward propulsion of food from the stomach into the intestines. Irrespective of the acid condition of the stomach the motility may be abnormally accelerated, slowed or entirely inhibited. It is clear that in cases of absolute cessation of motility, resulting, for instance, from a dilatation, dislocation or a pyloric stenosis, it is as useless to introduce artificially digested albumin into the stomach as it is to resort to native albumin. So also, when the motility and acidity are normal it is unnecessary to resort to artificially digested albumin. Even when the hydrochloric acid and peptone digestion is much reduced, or entirely absent, as in acute and chronic fevers, true gastritis, etc., the unaltered albumins may be perfectly utilized, as is clinically seen every day, and which both the clinical and experimental cases of total gastric extirpation have conclusively proved. It may be remarked, however, that certain particularly selected cases of an acidity with normal motility do not offer any direct objection to the use of artificially digested albumin, provided it does not prove too irritating to the gastro-intestinal canal.

Large quantities of many of the artificially digested albumins usually act as a laxative, and it is this action which recommends its moderate use in some cases or absolutely condemns its use in others. The great majority of artificially digested albumins are to be looked upon as gastro-intestinal stimulants, rather than nutrients which can be substituted for the maximum requisite quantity of albumin for any great period of time. Peptones and albumoses may be temporarily employed alone or as adjuncts to other foods in cases where there exists either a repugnance to ordinary food, where the mastication of food is difficult or impossible, or where there exists an incomplete mechanical obstruction in the esophagus, and where it is necessary to relieve the stomach entirely from mechanical irritation. In gastric ulcer, hyperacidity and in all cases where an over-production of the gastric secretion and hydrochloric acid is to be avoided, irrespective of the condition of motility, the artificial albumin preparations are not to be used. The other contraindications have already been referred to and need not be gone over again.

The subject of the feeding of artificially prepared fats and carbohydrates, while not exactly identical with that of predigested albumin, is nevertheless very similar to it, and many of the difficulties encountered in connection with the predigested albumins are also common to both the carbohydrates and fats. Various attempts have been made to increase the ordinary rate of fat absorption by mixing it with foodstuffs and chemicals and by emulsifying it in various ways. It has been found, however, that when the motility of the stomach is unimpaired and the pancreatic and biliary secretions are normal, the absorption of unaltered, native fat, such as is contained in milk, cream, eggs, butter, etc. is very satisfactory indeed. It has been shown that as high as 300 grams (about 10 ounces) of fat, representing 2790 calories, may be absorbed from the intestinal canal in twenty-four hours.

Practically no progress has been made in the direction of fat alimentation and this subject is now generally looked upon as belonging to impenetrable territory. However unpromising as the present outlook may appear for an advance in this problem, especially in conditions of general marasmus and in hepatic and pancreatic difficulties, the future may, nevertheless, offer a means for the eventual solution of the difficulty.

The logical, artificial conversion of starch into sugar for specific, dietetic purposes dates from the time when Liebig first prepared his infant's soup, although the empirical dextrinization and saccharification of starch has been practiced from time immemorial. When native starch is introduced into the mouth it undergoes a chemical conversion into maltose. Usually, however, this conversion is not completed until it reaches the stomach, and not even then if the contents of the stomach are decidedly acid. In the latter case the conversion is not completed until it reaches the small intestine. To insure the complete conversion of unaltered starch into sugar and the absorption of the latter into the circulation, it is necessary to prepare it in a very finely powdered form. Various preparations in which this precaution has been taken are to be found on the market and give very satisfactory results. The starch contained in these preparations may either be converted into dextrin by heat during their special preparation for the invalid, or into maltose by some particular malt solution or diastase. Investigation shows that from 500 to 700 grams of unaltered starch, representing 2050-2870 calories, may be almost completely converted into sugar and absorbed by the gastro-intestinal canal in twenty-four hours.

In infants in whom, as is now generally recognized, the diastatic functions of the salivary and pancreatic glands are but imperfectly developed, it is necessary to first convert the starch into dextrin and maltose, or preferably entirely into maltose in cases where it is thought advisable to feed with artificially digested foods of this variety. In adults good results are obtained from these foods in various salivary, gastric and intestinal disturbances in which unaltered starch is not properly utilized in the organism. Both dextrin and sugar are absorbed by the stomach as well as by the intestines, and, as one would expect, the diffusibility and absorptive rate of sugar is considerably greater than that of dextrin.

Just as in the case of the ingestion of predigested albumin, much depends upon the motility and absorptive condition of the stomach as to whether or not the converted starch or native sugar is properly utilized. Large quantities of converted starch or native albumin induce very decided gastro-intestinal irritation with fermentation and diarrhea. Although the ingestion of enormous quantities of starch never induces in the healthy individual an appearance of sugar in the urine, quantities of dextrose ranging from 100 to 250 grams are sufficient to induce a decided transient glycosuria. In the rational application, however, of dietetic preparations containing native sugar or converted starch, this undesirable effect is hardly to be feared. I simply wish to emphasize these circumstances to show the physiologic limitations of forced carbohydrate alimentation.

At times cases may arise in which it is desirable to substitute honey, cane sugar, milk sugar, glucose or fruit sugar for either native or predigested starch, and, when properly selected and carefully applied, these aid very materially in increasing the total caloric value of the diet of the invalid. To this class we may add the various malt preparations, which, in connection with their diastatic properties, possess a certain nutritive value.

On the whole, artificially prepared starches given alone or mixed with specially prepared milk foods have given good results in my hands. They offer a convenient form in which to exhibit this class of dietetic preparations, and, as a change from the various other foodstuffs, are generally very much relished by patients.

It is not my object, nor would it here be in place, to attempt a criticism on the value of these and other especially prepared foods in infant feeding. When used with judgment and discretion they undoubtedly often render valuable service; when they are indiscriminately prescribed, however, they give correspondingly bad results. From all this it will be seen with what difficulty every attempt is beset which strives to lessen the labor of the gastro-intestinal canal by the exhibition of artificially digested foods.

Unfavorable as this criticism may appear to the subject of artificially prepared albumins, I trust that it will not be construed as being intended as a reflection upon the efforts of manufacturers of artificially prepared foods. There are many who are honestly and sincerely interested in the production of a superior dietetic preparation and to them this is offered as a friendly criticism, which I hope may act as a stimulus to further efforts to produce a perfect artificially digested food—one free from the untoward secondary actions we have discussed. Much remains to be said on this subject, and it might have been of interest to have included a careful analysis of every class of artificially prepared foods in our discussion. Lack of time and space did not, however, admit of this, and I dwelt upon the albumins particularly, for the reason that they are so difficult of application and so universally misunderstood.

THE SOMATIC SIGNS OF BRAIN SYPHILIS.*

HUGH T. PATRICK, M.D.

Professor of Neurology, Chicago Policlinic; Clinical Professor of Nervous Diseases, Northwestern University Medical School; Neurologist to the German, Passavant, Maurice Porter and Wesley Hospitals.

CHICAGO.

This paper takes no cognizance of inherited syphilis or of the degenerative diseases in some way caused by specific infection, but is limited to the signs of histologically definable specific invasion of the brain.

Before entering upon the details of my subject, I beg indulgence while I enunciate half a dozen postulates relating to the clinical history and more general symptomatology of cerebral lues, which seem to me so important as to be inevitable as a preface.

1. Brain syphilis is most frequent in the first year after infection, next most frequent in the second year, less frequent in the third year and so on, about 50 per cent. of all cases occurring within three years after the primary sore. After ten years of quiescence, therefore, the appearance of cerebral syphilis is exceptional.

2. In reaching a diagnosis of a brain case, absence of a history of specific infection should have no weight in the case of women, and in the case of men relatively slight importance.

3. Syphilis of the brain is not synonymous with gumma. I do not know how the myth became current in the profession, but the average practitioner works in the obscurity of the tenet that brain syphilis means gumma and is utterly oblivious of the fact that this is the least frequent form of cerebral specific lesion.

4. Most frequently brain syphilis means syphilitic arteritis. Next in frequence come syphilitic meningitis and syphilitic infiltration of the cranial nerves, while a gumma comparable to a brain tumor is least frequent.[1]

5. Paralysis from brain syphilis (excluding paralysis of the cranial nerves) is most frequently caused neither by the pressure of a gumma nor by hemorrhage, but by thrombosis due to syphilitic arteritis.

6. Consequently, many cases of syphilitic paralysis are no more amenable to treatment than are those of cerebral thrombosis due to ordinary arteriosclerosis and atheroma (influence of age excepted), which means that the important symptomatology is that which precedes and presages paralysis, because it is at such time that prompt treatment obtains brilliant, almost miraculous, results.

7. Syphilis is never a "system disease." As the Anglican sage, Sir William Gowers, puts it: "As a general rule, if we find certain structures of common function selected for isolated impairment from among others of different function, we may be sure that we have not to deal with a true specific process."

In what follows mention is made only of those symptoms deemed by the writer to be most important by reason of their frequence or diagnostic importance or because, having been overlooked or forgotten by the average practitioner, they need to be called to his attention. No categorical enumeration of symptoms is possible in compass less than a brochure and a concise grouping of them is impracticable because the only systematic thing in the symptomatology of brain syphilis is the utter want of system, which suggests the first trait.

1. *Lack of Type.*—So strikingly consistent is brain syphilis in the production of apparent inconsistencies, that any brain case having an odd mixture of psychic and somatic disorder, a sequence of signs illogical as regards either time or localization, or a bizarre appearance, disappearance, reappearance, amelioration and aggravation of symptoms, should at once awaken suspicion of lues. For cerebral syphilis nothing is impossible. Insomnia, somnolence or an alternation of them; pain without anesthesia, anesthesia without pain or painful anesthesia; spasm without paralysis, paralysis without spasm or the two combined; monoplegia, paraplegia, hemiplegia, crossed paralysis, single or multiple cranial nerve paralysis, and any imaginable grouping of them; focal signs rivaling in neatness the most dexterous work of experimental pathology or a hodge-podge of symptoms carrying only confusion to the brain anatomist and physiologist; half-way manifestations, scarcely inflammatory, more than neoplastic; these are a few of the tricks of specific lesions within the cranium. A few years ago, when the London police found the remains of a mysterious murder, the body showing inexplicable mutilations, they said "Jack the Ripper." When the neurologist meets a brain case comformable to no rule, abounding in inconsistencies, ignoring anatomy, a clinical outlaw, he is very apt to say "brain syphilis."[2]

2. *Headache.*—In about 75 per cent. of all cases of cerebral syphilis headache is present. Notoriously nocturnal in its exacerbations, it may be vesperal, or even

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

[1] The foregoing is not to be understood as an attempt to controvert the fact that nearly all syphilitic lesions are histologically almost identical, i. e., granulomata—cellular accumulations—but merely as a protest against the baseless popular impression that brain syphilis simply means syphilitic tumor of the brain, and that the symptomatology of brain syphilis is simply the symptomatology of brain tumor.

[2] The only organic disease which can compete with syphilis in polymorphism, fluctuation and melange of types is multiple sclerosis.

diurnal and allow the patient to sleep all night. It is usually severe. The location is unimportant. In the beginning, although the lesion is constant, the headache is not; it may remain away for days or even weeks at a time and thus be mistaken for migraine or for malarial, infectious or stomachic cephalalgia. As the case advances, however, it becomes more continuous and may finally keep the patient in agony day and night. If occipital, the pain not infrequently radiates down one or both arms, even to the fingers, and may be accompanied by rigidity of the neck. Most frequently, but not always by any means, some part of the head is tender to percussion or pressure.

3. *Transient Attacks.*—These include every sort of fit, from the slightest to the most severe. They may be: 1. Attacks of dizziness, trifling or tumultuous. 2. Attacks scarcely to be distinguished from syncope. 3. Momentary losses of consciousness, exactly like petit mal. 4. Localized numbness or tingling—one side of face, one hand, etc. 5. Spasms, from the most trivial and restricted twitching to generalized violent convulsions. Typical Jacksonian fits are far from rare. Oppenheim says that the convulsions of syphilis are distinguished by their violence and frequency. My own experience is that while they are apt to be frequent and at times prolonged, the spasm is more often slight, not violent.

Some of these fits are apoplectoid rather than epileptoid. The patient suddenly has a seizure, with or without loss of consciousness, with or without spasm, but attended with loss of power more or less marked, more or less transient. Later, of course, such an attack may be more grave and the paralysis permanent. Epilepsy or apoplexy between 20 and 40 should always awaken suspicion of specific disease.

4. *Cranial Nerve Paralysis.*—Frequent, striking, imperative in their indications are palsies of the various cranial nerves, and of these oftener involved than any others are those pertaining to the eye. I need only mention that Alexander's statistics showed 72 per cent. of unilateral paralyses of the third nerve to be due to syphilis, and Uhtoff concludes from his observations that only 15 per cent. of all cases of cerebral lues are without eye symptoms. I should say that, in the absence of traumatism, at least 90 per cent. of all cases of ocular paralysis in adults are caused by brain syphilis, locomotor ataxia, general paresis, and brain tumor, and of these by far the most frequent causes are locomotor ataxia and syphilis—diseases that may usually be distinguished at a glance. Of primary optic atrophies more than 90 per cent. are certainly due to tabes, syphilis and general paresis. Tabes causes the most. Choked disc and optic neuritis may be mentioned here. They are not so very frequent. When present they are almost pathognomonic of intracranial organic disease, but serve in no way to distinguish luetic from other changes.

In this connection, too, I may speak of disturbances of the visual field. The long course of the visual tracts, almost from pole to pole of the brain, makes them liable to injury by lesions of various location and, besides, the exposed position of the optic nerves and optic tracts at the base causes them to be involved with frequency. Currently, the visual field is examined far too infrequently. Alterations in the field may be quite unknown to or erroneously interpreted by the patient and thus escape knowledge of the physician unless systematically looked for. Besides affording indubitable evidence of organic disease they may, alone or in conection with other signs make the localization easy.

All of these ocular signs are apt to have the inconsiderate disregard for anatomical facts and established types before spoken of. There is no necessary correspondence of pathological findings to clinical picture. The whole third nerve may be embedded in a gummatous meningitis and yet only part of the fibers suffer, while complete paralysis in all its branches may depend upon almost undiscoverable changes. Unaccountable alterations in the visual field, blindness without changes in the fundus, appearance and disappearance of symptoms so sudden as to suggest only functional disease are some of the many manifestations showing the capricious character of brain syphilis.

Less frequently than the ocular nerves, but still quite often, are the fifth and seventh attacked, and with the latter the auditory is very apt to be involved. The first sign of involvement of the fifth is paresthesia or pain in the distribution of one of its branches. As the disease progresses these irritation symptoms spread to other branches. With the pain, maybe shortly preceding or following it, comes impairment of the tactile sense, the patient then presenting anesthesia dolorosa—a complex almost invariably due to organic disease of the nerve trunk. The fifth is affected on one side only. Paralysis of the seventh is, of course, of the peripheral type, and may affect both nerves, either alternately or simultaneously, although unilateral trouble is the rule. Lesion of the auditory, causing tinnitus, deafness, aural vertigo, or all three, is rare without implication of the facial as well.

Cranial nerves below the eighth are affected with less frequency, but none are exempt. Dysphagia, partial paralysis of the tongue, alteration in the pulse rate, laryngeal paresis, partial paralysis of the sterno-mastoid and trapezius muscles and cerebellar symptoms, alone or in combination, are produced when syphilis invades the posterior fossa of the skull. In case the basilar artery and its branches bear the brunt of the attack, materially interfering with the bulbar and pontine circulation, the grouping of cranial nerve signs will be that of bulbar paralysis—the glossolabio-laryngeal complex.

Before leaving the subject of cranial nerves, I can not refrain from again calling attention to the extreme irregularity of the voicings of syphilis and to the value of this lack of system as a diagnostic pointer. While cerebral lues may affect the cranial nerves as would any basilar disease, invading those close together and causing gradually increasing symptoms as the disease progresses, it more frequently acts in a more erratic way. One nerve on one side and quite a different nerve on the other; one anterior and one posterior nerve on the same side; paralysis of one nerve, disappearance of this paralysis and then paralysis of another, nearby or at a distance; paralysis of some fibers of one nerve and then serious involvement of another without the first growing any worse; these are some characteristic vagaries.

5. *Addition of Spinal-Cord Symptoms.*—This is perhaps as good a place as any to speak of the complications of cerebral with spinal syphilis. While it savors of Erin to speak of spinal symptoms as part of the signs of brain disease, it is a fact that syphilitic disease of the cerebral meninges does often spread to the spinal membranes. When, therefore, to the characteristic signs of cerebral disease are added symptoms pointing to disease of the cord or its membranes, the diagnostician is materially aided in coming to a conclusion.

6. *Impending or Accomplished Thrombosis.*—As be-

fore stated, arteritis or arterial cellular infiltration is the most frequent form of brain syphilis. Syphilitic meningitis must inevitably compromise arteries and veins and even a gumma may disclose itself principally by the invasion of adjacent vessels. Obviously, then, many of the signs of cerebral lues will be those caused by local abnormalities of circulation, and they resolve themselves almost entirely into the signs of impeded circulation and arterial occlusion. Most of these signs have already been mentioned, but it seems advisable to review them from the standpoint of arterial lesions. Indeed, it is well to frequently remind ourselves that although the symptoms of cerebral syphilis are due entirely to injury of nerve cells and fibers, the disease is not primarily one of the nerve elements at all, but of extra-neural tissues—arteries, veins, membranes, nerve sheaths. To involvement of arteries at the base of the brain, Heubner attributed most of the intellectual and mental symptoms of brain syphilis; a great many of the early and late somatic signs are directly attributable to partial or complete occlusion of arteries. Among the earlier, besides headache, are transient attacks of dizziness, of numbness of one hand, one foot, one side of the face or tongue; transient aphasia or paraphasia, alalia or dysphagia; temporary diplopia, ptosis, or dilatation of one pupil; sudden weakness of one hand or leg, or partial hemiplegia which rapidly disappears; localized clonic spasm or twitching —all of the foregoing without loss of consciousness. As the disease is never confined to one arterial twig and very often affects the nutrient vessels of parts differing widely in function, these early, so-called premonitory signs may present peculiar associations. Dilatation of one pupil and paresthesia of a hand, numbness of the left face and clumsiness of the right hand, partial aphasia and slight dysphagia, diplopia and weakness of one leg, may be noted as illustrations.

Then there may be a general neurasthenic and myasthenic condition with insomnia or moderate somnolence without focal signs. Later come more pronounced symptoms; the dizzy spells become brief losses of consciousness, the pareses are less transient and disorders of speech more enduring. It is only one step more to a grave apoplectic attack from thrombosis of a considerable artery. If the vessel belong to the cortical circulation and be not too large, such an attack may be rapidly recovered from, but if such considerable vessel supplies the basal ganglia or cranial nuclei, the disability is permanent, and if the artery be a very large one of any part the result is permanent disability or death. As in thrombosis from lesions other than specific, a complete hemiplegia may occur without loss of consciousness, or with only moderate confusion or somnolence. This is not true of hemorrhage. In many cases the hemiplegia comes on in such a way as to clearly indicate either temporary arrest of circulation or partial occlusion of an artery followed by its complete closure or, what I believe to be more frequent, thrombosis of a small branch followed by occlusion of adjoining branches or of the main artery by extension of the intra-arterial clot. Such a course of intracranial proceedings is evidenced by restricted or very slight paralysis, followed in some hours or days by more extended or complete disability.

I believe that largely to arterial invasion is to be attributed another of the frequently observed features of brain syphilis, viz., progress by separate steps or increments. Without appropriate treatment, cerebral syphilis progresses more or less rapidly for the worse, but never uniformly, always by fits and starts, often with intercurrent improvement. Not rarely these increments affect different parts. A small artery becomes so badly damaged that circulation in it is stopped. Before a second calamity takes place in that immediate vicinity, another arterial twig at some distance suddenly goes out of commission, adding one more sign to the clinical picture, while that caused by the first stoppage may be improving.

Of material assistance in some of the earlier cases are increase of the deep reflexes and incoördination. The patient may make complaints such as indicate merely functional disease and the physician may detect neither anesthesia nor motor impairment, but careful examination may show increased deep reflexes on one side, as compared with the other, or slight incoördination in finer movements.

7. *Peculiar Stupor.*—While not wishing to trench upon the topic of Dr. Dewey, which none can handle so well as he, I would slight my own subject were I not to mention the somnolent, semi-stuporous condition which occurs more frequently in cerebral lues than in any other brain disease. Combined with one or more of the foregoing somatic signs it is well-nigh pathognomonic and even alone is strongly suggestive. In this condition the patient seems to be almost comatose, but can be roused and when once awake is practically rational, although he may be decidedly irritable, not to say bellicose. The condition was long ago likened to a drunken state; after being roused and responding to enquiries, the patient at once lapses into his previous stupor. Without fever and preceded by or combined with severe headache, the symptom means grave organic brain disease, in numerous instances, syphilis.

8. *Fever.*—Cerebral syphilis may be considered to be an afebrile disease. Fever is exceptional unless pons or medulla oblongata be involved, when rise of temperature may be slight or considerable. In some cases the fever has seemed to me to be caused by bad condition of the gastro-intestinal tract and absorption therefrom.

9. *Vomiting.*—This occurs in many cases, more frequently when the posterior fossa is invaded and when a large gumma or extensive meningitis is present. Such emesis, although of cerebral causation, may take place only when the stomach is full and may be determined more by one sort of food than another. Nor should it be forgotten that cerebral vomiting is not necessarily projectile.

10. *Polydipsia, polyuria* and *polyphagia* are not unusual results of brain syphilis, the last being the least frequent.

11. *Insomnia* is not rare, aside from the inability to sleep on account of headache, and besides vertiginous attacks, constant dizziness may be present.

THE PSYCHOSIS IN CEREBRAL SYPHILIS.*

RICHARD DEWEY, A.M., M.D.
WAUWATOSA, WIS.

When I came recently to consider attentively the subject assigned me in this discussion, I was so doubtful as to the production of anything of value that I asked the chairman to excuse me, but as both the present chairman and the chairman of last year renewed their request, I have complied with their wishes as well as possible.

When one attempts to lay down the lines upon which the subject should be treated, several questions arise which require to be first taken into consideration. One is the evidence of syphilis. Another, the very frequent existence in these cases of causes other than syphilis which have their share in determining the mental state—such as alcoholism; senile changes; arterial disease; kidney and heart disease and tumors, of non-specific origin.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

If the rule were made and followed of first catching your specific lesion and then excluding alcoholism and non-specific vascular changes, etc., a portion of the foundation for much writing on this subject would crumble away. On the other hand, syphilis is not and can not be excluded, even when neither history of it nor somatic signs are attainable. Fournier states that syphilitic disease of the nervous system is found more frequently than are the external signs of syphilis. Berkely attributes to syphilis all cases under 40 of hemiplegia or monoplegia and mental disturbance, where cardiac and renal disease were not found; also obscure dementias between the years of 25 and 40. This method of reaching a diagnosis must have an element of uncertainty, though doubtless in a general way the deductions are correct. There are probably as many cases in which syphilis is concealed or remains undiscovered as there are incorrectly diagnosed, but striking a balance by this method is not satisfactory for our present purpose.

It would seem that the reasoning adopted in many cases was something like this: "Here is a case of organic brain disease, coarse or fine, paresis, hemiplegia, monoplegia, suspected tumor or vascular lesion. It is antecedentally and consequentially probable the patient has had syphilis; therefore this is cerebral syphilis." Then the mental manifestations are sometimes taken up and treated as due to syphilis without positive evidence either before death or postmortem, and perhaps without considering whether the same mental states are not closely paralleled by cases certainly non-specific, or whether the findings may not be due to general and not specific causes, even though syphilis be present.

One instance of syphilitic psychosis that may be mentioned here is the mental state found in syphilitic tumor of the brain; but can any one distinguish between the psychopathic effects of a specific and a non-specific tumor? Again, how are the arterial disease due to syphilis and that due to other causes to be differentiated in their mental phenomena? Consider in the same way the effects of edema and intra-cranial pressure, with interruption or irritation of tangential tracts; also those of the various toxins. These morbific agents must destroy or derange the "cytopsyche" and the "histopsyche," assumed by some German writers to preside over the cell and tissue life (and I believe countenanced even by Haeckel); but the relation, if any, between the unconscious soul ascribed to the units of structure and the conscious soul that has for its instrument the entire brain, is something as yet beyond scrutiny. The cœnesthetic sense which is essential to soundness of mind is impaired in all psychoses. The association tracts belonging to the various brain centers are interrupted by syphilitic connective tissue overgrowth, or by poison or malnutrition, from primary degeneration of neurons, but how does this differ from the disease or destruction of association tracts from other brain changes, or from neuron degeneration from other poisons?

Berkely[1] in his recent work states: "Lues never directly affects nervous tissues." Moebius, as quoted by Bannister,[2] treating paresis as a syphilitic toxin disease, asserts: "There is only one kind of general paralysis and only those have it who have previously had syphilis." Is general paralysis a psychosis of syphilis simply? If so, we have at least one syphilitic form of insanity, but Moebius' claim is by no means fully substantiated. Probably as many pathologists would be found to deny as there are to affirm that tabes and general paralysis are exclusively syphilitic in their origin. Assuming that these diseases may be due to other causes than syphilis, can any one draw a clinical picture of these diseases when caused and when not caused by syphilis? It seems to me that if no one can distinguish between specific and non-specific paresis or tabes, where the pathology is comparatively well defined, it is all the more impossible to define the part syphilis may play in the forms of mental malady where the pathogenesis is more obscure. Consider further, syphilitic hypochondriasis, so-called "syphiliophobia," and insanity occurring with the very onset of constitutional syphilis. In all such cases lowered brain nutrition, perhaps purely functional, is capable of accounting for the conditions, and it is not necessary to call in syphilis to explain them. High authorities affirm and deny that soft chancre or suppurating buboes are followed by constitutional syphilis. The views of Fournier—as good an authority as any—have changed from one extreme to another, and of late a new perplexity is introduced by affirming that hereditary syphilis plays an important part in the development of psychoses, especially in the adolescent period. Here again an obstacle to the full understanding of the case arises, because the proof of hereditary syphilis is not always convincing, since dementia, praecox, paranoia, and hebephrenia have not as yet been studied so that those of specific and non-specific origin can be differentiated, neither are writers agreed as to the adolescent form of paresis.

In a recent paper by A. W. Hurd[3] it is stated that syphilis may cause, 1, any simple psychosis; 2, paresis; 3. pseudo-paresis. By a simple psychosis I take it is meant one which has nothing characteristic of syphilis. Paresis is the same thing, whether caused by syphilis or not. Finally, in "pseudo-paresis" it is claimed to be characteristic to find a confused mental picture, as of paresis "toned down," or cerebral syphilis "heightened"; to find that motor disorders or cranial nerve symptoms precede; that hypochondria or acute delirium may appear early; that paralysis rather than ataxia plays the leading rôle; that mental dulness and a "vacant expression" are more noticeable, while we find that a gradual change in disposition, grandiose ideas and a sense of well-being are more marked in paresis. It is noted that motor symptoms, cranial nerve symptoms and ataxia are utilized to aid in diagnosis, but these I am not able to take into account in treating of purely mental phenomena, as my subject requires.

In a paper by J. H. McBride,[4] read in this Section one year ago, it is stated: "Syphilitic insanity may mimic every known form of mental derangement;" he also says that there is "nothing characteristic in the mania" or the depression due to syphilis, but that, if the entire history be considered, irregular features will be found; that in mania there will be the earlier appearance of confusion or weakness, with intervals of quiet and semi-lucidity; in melancholia, brief depression, much confusion, outbursts of excitement, periods of stupor and early dementia. "These," he says, "may be regarded often as circumstantial evidence of a specific origin." The writer also mentions "loss of mental power, of self-control, of the self-regarding virtues, of moral sense, the detachment of life from the delusions," and many other morbid mental phenomena as "prominent characteristics." There is scarcely one of these phenomena or any combination of them which may not appear in an equally irregular manner in cases where there is no question of syphilis. A "confused mental picture," a "toning down" or "heightening" of various symptoms, an irregularity in the order they assume, predominance of paralysis or of ataxia or of cranial nerve symptoms, "hypochondria," "acute delirium," "vacant expression," etc., are symptoms that purely non-specific psychoses or those arising from alcoholism or non-specific arterial changes may present. So with the peculiarity of seeming to mimic other forms of insanity; and of irregular and atypical features or succession of symptoms.

[4] Mental Symptoms of Cerebral Syphilis. The Journal A. M. A., Feb. 2, 1901, p. 297.

The arguments in favor of syphilis from the "bizarre" and irregular character can have but small weight since "bizarrerie" is something we constantly see in cases where the question of syphilis is known not to enter, and certainly "loss of mental power" or of "moral sense" and of "the self-regarding virtues" have in them nothing that would aid in the diagnosis of a syphilitic psychosis.

If these two able observers find nothing in the mental phenomena more distinctive, one is inclined to think that it is because there is possibly nothing that is distinctive.

The tendency to "remissions" and to periods of return to apparent sanity does seem to mark syphilitic cases especially, though also known in those that are not syphilitic. In this matter again there is a difference of opinion as to whether the return to sanity is complete. Some writers, and among them Mott, claim that a certain dementia or weakening always remains; but I have known of cases where the return to normal condition was so complete that no expert could tell the difference, and such are reported by others. Mott explains these fluctuations by the fact that when the remissions occur, the disease is external to the nerve cell and functional in its nature.

It is doubtless true that the permanency of insanity and the failure to recover in simple acquired psychoses, may be due to the complication of syphilis, either hereditary or acquired. Some writers have given failure to recover as an indication or presumption of syphilis, but this fact itself helps not at all in the diagnosis of syphilis. Failure to recover is unhappily too frequent in all forms of insanity.

A correspondence may exist between the difference and variable nature of psychic symptoms and the irregularity of the pathologic changes of syphilis—so largely vascular in their origin. The irregular and temporary attacks of aphasia are somewhat characteristic, but are also found in other cases.

Some writers who claim lacunæ in the memory as characteristic, fail to note that lapses and gaps of memory are common in other forms, particularly alcoholic and epileptic forms, and yet these latter will be apt to be associated with acute attacks or other accompanying signs. It is perhaps questionable whether systematized delusions are ever found in syphilitic brain disease, unless there be a background of paranoia or degeneracy.

It is agreed that the anterior portions of the brain, frontal and central, are more open to syphilitic infection and this gives some characteristic significance to the frequent dulness and stupor. Again, the admitted correspondence between senility and syphilitic insanity speaks only for lack of characteristic features. Spitzka[5] gives the figures of Snell, who found that 75 per cent. of the cases of paretic dementia were due to syphilis; of Erb, who found a similar proportion of cases of tabes due to syphilis; of Mendel, who found 117 out of 291 such patients were syphilitic, while on the other hand Ripping found only 12 per cent. with a syphilitic history. Spitzka himself found syphilis in 33 per cent. of the pauper insane of New York. Clouston, in over 3000 cases, found but 16 of syphilitic insanity. Spitzka remarks that the attempt to test the question of syphilis by specific treatment fails, because in several cases spontaneous remissions occurred and in others the most energetic treatment gave no results. Then, too, specific treatment has been found useful where infection could be positively excluded. Finally, Ripping claims to have found syphilitic patients recover from insanity where no specific treatment was applied.

These statements, as well as innumerable others to be found in the literature, tend to throw doubt on claims that any given psychopathic condition is syphilitic, and yet as was remarked by Kraft-Ebing and agreed to by Mott: "The more we study paresis the more we find it associated with syphilis;" and the former declares with a measure of truth that civilization and "syphilization" go together, however discreditable this fact may be to the former.

The recent report of the Pathologic Laboratory of the London County Asylums by F. W. Mott[6] contains valuable information concerning the pathology of syphilis, the structural changes and to some extent the mental symptoms. That which seems most pertinent to the present inquiry in Mott's work is the placing in clearer light the fact that syphilitic brain disease, as distinguished from paresis, affects, primarily, vessels, lymphatics and membranes—mesoblastic structures—and the degeneration of neurons is secondary. Paresis, on the other hand, is a primary decay of the neuron itself, but it is not clear that the mental symptoms of the two processes can be differentiated. Indeed, Mott gives the phenomena of irritation and other psychic symptoms as characteristic of early changes in both. The primary progressive degeneration of neurons starts at the highest and latest developed structures, speech and association centers, and attacks by preference the frontal and central regions. Mott describes stupor, dementia, weakening or loss of memory and intellect, and many other symptoms, but does not give any distinctive characteristic of different syphilitic processes; neither can we distinguish these as being different according as syphilis is or is not found. Mott considers "stress" to be the important proximate factor in the development of brain disease, in one affected with syphilis. Stress is, however, perhaps equally the proximate cause in psychoses where syphilis is not concerned.

Since as yet we have in psychiatry so little in the nature of known definite psychopathic symptoms which can be associated with molecular or even coarse changes in the brain; since as yet we know nothing of the *modus operandi* of mental changes as associated with pathologic findings, and since our classifications of mental disease are in a purely tentative and conjectural condition, it seems premature to attempt to formulate syphilitic psychoses. The very inconsistency and lack of type in symptoms taken by some to be indications of syphilis, are interpreted by Kraepelin to be characteristic of chronic and permanent mental deterioration—Verbloedung's processe. We all meet with cases for which there seems to be no place by any method of classification as yet devised.

[6] Annual report of the Pathologic Laboratory of the London County Asylums, 1900. Abstracted by J. H. McBride, Southern Cal. Pract., April, 1901.

Clinical psychiatry must unite psychical events in the course of each recognized psychosis, with a negative or positive report from the autopsy table, before the influence of syphilis on mental operations can be determined. We can not doubt but that psychic life is intimately associated with matter, i. e., with brain cells, but we are as yet without data which would enable us to connect objectively the functionating of those cells either in health or disease, with any changes in their form or substance. Even the pathology of general paralysis, the best known of all, is only indefinite as to mental changes and their relation to physical changes.

I am aware that I have only touched the borders of this far-reaching subject, and that most of what I have written is only of negative value, if of any at all.

I have sought something more tangible in reviewing my records of the past six years, covering over 1200 cases of all forms of nervous and mental disease. I found among these 45 cases of well-substantiated, constitutional syphilis. Doubtless an equal or greater number which I rejected for want of definite knowledge might have been included without serious error, but considering only these 45 cases, they were made up as follows: 17 were diagnosed as paresis; 12 as syphilitic brain disease with symptoms of organic lesion; 7 were cases of psychoses with marked delusional characteristics and without symptoms of brain syphilis, the mental symptoms taking the form of delirium, stupor, extremes of exaltation and depression, aphasic attacks and mild dementia; 4 having ophthalmoplegia and optic neuritis: 4 were cases of hypochondriacal melancholia, and of these, 3 temporarily improved, the other was a morphin case: 2 were cases of tabes with emotional weakening as the only mental failure, and there was one case each of slight dementia, melancholia and dementia paralytica of senile form. The type of mental disorder in the 17 cases of paresis was expansive in all except 2; marked confusional condition was present in the two depressed cases, and in 9 of the expansive cases confusion was also a very prominent feature.

These cases were gone over and tabulated with reference to the following points: The type of hallucinations and delusions, where present; the cranial nerve symptoms; the evidence in each case of syphilis; the habits and occupation; the outcome as to the history of marked stress as a factor producing the mental disease, and the time of infection prior to appearance of psychopathic symptoms.

I found, however, that these tables possessed but little significance, partly because no useful deductions could be made from such small numbers, and partly because the exclusion of so large a number of probable cases for want of a positive diagnosis seemed to me in a measure to vitiate the result.

Progress in Peru.—The Lima medical papers are rejoicing over the accession of a portable disinfecting oven, and the bacteriologic laboratory recently installed in the public hospital, which, by the way, bears the unique name of the Second of May Hospital—"Dos de Mayo."

SYPHILIS OF THE NERVOUS SYSTEM—ITS GENERAL PATHOLOGY, WITH REMARKS ON TREATMENT.*

F. W. LANGDON, M.D.
CINCINNATI, OHIO.

The initial lesion of syphilis must be viewed, in the light of our present knowledge, as a wound plus infection, the infecting material being probably of bacterial origin.

The first nervous changes following such infection are localized at the sight of the initial lesion, and have been well described by Berkley.[1] Briefly, these changes consist of a combined interstitial and parenchymatous neuritis, due, in the investigator's opinion, to, 1, compression by the round-celled exudate; 2, endarteritis, interfering with nutrition; 3, local effect of a "virus."

The conditions found in the nerves are described as, 1, obliteration of lymph spaces; 2, disappearance of axons; 3, a "glassy" degenerated appearance of, the myelin.

These changes were limited to the nerves imbedded in the round-celled exudate; those nerves not so surrounded being normal, or approximately so. Root-neuritis, cranial and spinal, and peripheral mono-neuritis may occur as secondary lesions.

Syphilitic multiple neuritis has also been reported, one case by Fry,[2] a year after the initial lesion; and a case by Cestan,[3] who notes three others with more or less doubt. The extreme rarity of the affection and the possibility of other causes in any given case tend to render the diagnosis problematic.

The second evidence we have of invasion of the nervous system by the disease or its products, is in the production of fever—"syphilitic fever"—often overlooked and sometimes misinterpreted.

The actual pathologic process at work here is unknown. Presumably, in the proliferation of the microbes of the disease, a toxin is set free in the tissues, which, carried by the blood stream to the cerebrospinal axis, irritates certain hypothetical thermo-genetic centers, or depresses certain other centers equally hypothetical, which are assumed to control or direct thermolysis. Another explanation to be considered leaves out of account any such "centers" and attributes the febrile process to alterations in the chemical constitution of the tissues generally, by the toxin of the disease. These alterations giving rise to perversions of metabolism with increased heat production or diminished heat dissipation.[4]

The third group of processes to be considered, that which is by far the most important to us, in a practical sense, is the inflammatory group whose characteristic lesion we call a "gumma."

The great fact of importance in this group, as regards nervous syphilis, is that gummatous syphilis in its beginning is a vascular syphilis.

Since all vascular organs are, in their developmental nature, of connective tissue (mesoblastic) type, it follows, as a corollary, that vascular syphilis is necessarily connective tissue syphilis. Hence to the tissues of this type (blood, dermis, basement membrane, areolar tissue, bone and cartilage), must we look for the initiation of the pathologic processes which invade the nervous, as well as the other anatomical systems.

---

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

Nervous tissue proper, therefore, owing to its nonvascularity, is never the primary seat of inflammatory processes, whether these be due to syphilis or to other causes.

While it may be said to be an accepted axiom therefore, that gummatous syphilis is primarily vascular syphilis, it does not follow that it must be an arteritis or a phlebitis. It is often a lymphangitis, using this term in its broad sense, to cover involvement of the lymph-channels generally of the nerve centers. Thus the so-called peri-arteritis is often a lymphangitis in its inception, beginning in the peri-arterial lymph sheath. There are reasons for the belief that gummatous meningitis of the diffuse form may be also of lymphangitic type. As regards the best known vascular lesion, arteritis, the discussion as to whether a "peri-arteritis" (Baumgarten), or an endarteritis (Heubner), is the *more characteristic vascular lesion of syphilis,* would seem to be a superfluous refinement in localization from either a diagnostic or a therapeutic view-point, since in either event the exudate is within the wall (not within the lumen) of the vessel, and eventually involves its entire thickness.

The important event in syphilitic arteritis is the impairment of the nutritional integrity of the endothelial lining, whereby thrombosis with its resulting necrotic softening is directly produced.

It is customary to picture the changes in the vessel wall as a heaping up of proliferated cells, presumably derived from the deep endothelial layers of the inner coat. It is not probable, however, that the closure of the vessel is ever due merely to mechanical effects of this accumulation. Long before closure would occur from this cause, the inner lining, which must be continually shed, molecule by molecule, has been replaced by the rapidly reproduced and hence imperfect cells of the deeper layers. These again are being gradually deprived of their nutrition—from the vasa vasorum via the intramural lymph spaces—by reason of the increasing pressure of the exudate in the middle and other layers of the vessel wall, and possibly in addition are directly affected by the toxin of the disease. Hence, it is only a question of time that the inner wall of the vessel at the affected area comes to be lined by an endothelium defective in nutrition, possibly actually necrotic in places. Thrombosis, then, is the inevitable result.

As regards the direct local cause of the endarteritis, we must assume that the active agents in its production, which are at present supposed to be bacteria, are carried to the points of inflammatory reaction by the vasa vasorum.

We reject the main blood stream (of the lumen) as a source of the infection of the wall, by reason of the fact that inflammation presupposes stasis followed by exudation. Stasis, however, is not likely to occur in a large or moderate-sized artery. It is only in the capillary plexuses of the vasa vasorum and their nutritive successors, the intramural lymph spaces; or again, in the terminal capillary plexuses of the ordinary artery, that conditions favorable to stasis occur.

Pathologically, therefore, *syphilis of the central nervous system is primarily a lymphangitis, phlebitis or arteritis,* or any combination of these. The product of the inflammation is an exudate consisting chiefly of small round cells with a tendency to, 1, central necrosis, when in massive collections—gummatous tumor—or, 2, a tendency to fibroid organization when spread out in thin layers—gummatous meningitis, diffuse arteritis, etc.

In accordance, therefore, with the stage and progress of the process we may have, 1, a gummatous thickening, plaque or tumor; 2, a caseous abscess; 3, a cicatrix. In either event the nervous manifestations are secondary and due to, 1, thrombotic occlusion of nutrient vessels causing necrotic softening in their areas of distribution; 2, mechanical pressure causing secondary degeneration of neurons or their processes; 3, interference with the return circulation in lymph channels, causing local toxic states; 4, arteriosclerosis of varying type, probably responsible for various nerve degenerations of chronic character, e. g., nuclear palsies, locomotor ataxia, paresis, etc.

The question naturally arises: Is all inflammatory syphilis essentially alike, i. e., due to gummatous deposits of varying shape, in and around arterial, venous or lymphatic channels? This must probably be answered in the affirmative; the differing "types" of gummatous disease, meningitis, massive gumma, and arteritis "obliterans" being variations due to differences in size, number and distribution of foci. The possibility of a "mixed" infection in some cases must be conceded; to this abscesses proper may be due at times.

Hereditary syphilis as it affects the nervous system, may develop as a gummatous arteritis or meningitis, pathologically identical with the acquired form in adults. Many of the infantile hemiplegias and spastic paraplegias are probably of this type. Defects of a developmental nature, however, also occur in children, showing themselves in the various forms of idiocy and imbecility, which probably rest in great part on a foundation of vascular degeneration. It is quite probable that the proportion of children showing distinct syphilitic lesions of hereditary origin is commonly overestimated, as compared with the non-syphilitic from the same class of parents. Almost every practitioner can recall numerous cases where the children of syphilitic parents have all escaped; and other cases where one child is marked with, and others free from, syphilis. Statistics bearing on this point would be desirable.

We must not lose sight of the fact that gross lesions, i. e., meningitis, gumma, arteritis followed by softening, are not the only results of syphilitic infection of the nerve centers. Encephalitis, in multiple and minute foci, situated about the terminal capillary plexuses of the cortex, may probably occur, damaging various association tracts and operating as an important factor in the production of syphilitic epilepsy, some of the psychoses, etc. Accurate observations on this form of encephalitis would be desirable.

What is the most frequent site of the gummatous process in the nerve centers? This question is evidently a difficult one to answer, since many cases present multiple lesions. Most authors state that, 1, basilar meningitis is the most frequent cerebral lesion. Next follow in order, 2, meningo-encephalitis of the convexity; 3, arteritis with thrombosis and softening. In the cord, the most frequent lesion is said to be a meningo-myelitis; next to that arteritis with local softening. The writer's experience is at variance with this statement as shown by the following analysis: In 100 consecutive cases, about equally distributed between hospital and private practice, the preponderating lesion was diagnosed as follows:

Thrombosis with softening (hemiplegia)........	41
Meningo-encephalitis of vertex.................	23

Basal meningitis	11
Cerebrospinal disseminated lesions	10
Focal myelitis (including also "transverse")	12
Meningo-myelitis	3

Excluded from the enumeration, but in serial connection with it are:

Massive gumma	1
Psychoses (probably of meningitic or encephalitic origin)	2

Another question of importance is: Has chronic diffuse syphilitic arteritis any distinguishing features by which it may be recognized from arteriosclerosis due to other causes (chronic uremia, gout, alcohol, etc.)? To this most competent observers reply in the negative.

It has been assumed[5] that, in the localized softening following a syphilitic thrombosis, we have an "ordinary" or non-specific lesion to combat. Is this true? Probably it is, for a short time, of the softened area itself. But what follows this softening? In the surrounding tissue, hyperemia, exudation, proliferation; in short, secondary inflammation. Is this non-specific? It would be remarkable to think it was when we reflect upon the proximity of the original infected vessel. We all know the tendency of ordinary external wounds in a syphilitic to take on the "specific" inflammation; and how often they heal slowly or refuse to heal, until treated with anti-syphilitic remedies.

NATURAL HISTORY OF SYPHILIS.

During the early or "primary" period of the disease, following immediately upon the infection, we must assume the local proliferation of the microbes (bacteria?) and the collateral production of a toxin which produces a localized degenerative neuritis as well as the "general" symptoms, fever, malaise, muscular pains, etc. This period probably *terminates*, as does the febrile stage of the ordinary exanthemata, by reason of the production of an antitoxin which terminates the life or activity of the micro-organisms in great part, leaving, however, a few, possibly in a "sporule" stage for the future development of foci of gummatous inflammation in various situations. This is probably the natural course of the disease when uninfluenced by treatment of any kind.

The writer has seen such a case, untreated for thirty years, in a man of 55, who had received internal medicine (nature unknown) for only a couple of weeks at the time of the initial lesion. All these years he had been subject to repeated crops of subcutaneous and intramuscular gummata which had caseated and cicatrized, with little or no interference with his general health, and which he ascribed to hereditary "scrofula" in his system, of which there was, in my opinion, no evidence. When he consulted me for a paraphasia verbalis without paralysis due to slight thrombotic softening, he had two of these caseating gummata on the back, each as large as a pigeon's egg, of which he made no mention, so accustomed had he been to the presence of similar lesions for thirty years. On stripping him for examination these were discovered, and in addition, dozens of characteristic cicatrices, and intra-muscular indurations, situated on trunk and extremities, marking the sites of former gummata. He made a fair recovery from the aphasic symptoms and was kept upon mercury and iodids at intervals for about two years, during which time he enjoyed fair health. He had all his life an especial liking and capacity for mathematics, and this was apparently not diminished. As he lived at a distance he became somewhat irregular in his visits and when he consulted me again, after an absence of some months, he presented a marked motor aphasia, with slight right hemiplegia and a mild degree of dementia, probably all due to multiple foci of softening. Death followed in a few months.

The gummatous process is, therefore, in a measure self-limited. It is also in its inception to be viewed as a conservative process; like all inflammation it is evidence of resistance to an invader. When this disappears the gummatous process, like other inflammatory actions, ceases. What checks it? Three things:

1. The insufficient blood supply at its center, leading to necrotic softening and caseation.
2. The possible (even probable) development of an antitoxin which checks the local proliferation of microbes.
3. Removal of the necrotic tissue in part, by the leucocytes of the surrounding exudate, or, in the nerve centers, possibly by the mossy glia cells (scavenger cells of Bevan Lewis).
4. Organization into cicatricial tissue of the remaining elements of the inflammatory exudate.

Pathology is certainly of greatest value when it points the way to a rational therapy. May we hasten in any manner the more desirable of these processes? This, it seems to me, is the therapeutic problem to be solved.

While the limits assigned to the present paper forbid any extended or detailed remarks on treatment, some general considerations of the subject may be permissible.

We have come to speak so confidently of treatment by mercurials and iodids as "specific" treatment, that it does some violence to our therapeutic optimism to question their "specific" attribute. And yet it seems that we must logically admit this to be a fragile idol, likely to be shattered by the cold logic of the laboratory. Do these remedies destroy the germs of the disease? Few will claim this at the present day. The hypothesis of Gowers and others, that they may destroy the germs but not the "spores," is an attempt to explain the obtrusive fact that they do not, as a rule, prevent future gummatous developments. How then may mercurials and iodids act in gummatous disease? They are erroneously called 'absorbents," but we know that no drug is an absorbent. The very term absorbent, as applied to drugs, is almost as objectionable as that other absurdity, "keeping the bowels in a soluble condition."

What useful purposes may these remedies subserve in promoting the disappearance of syphilitic exudates? Simply and solely to destroy the already feeble vitality in the newly developed cells of the gumma, to poison *them in fact*, after which fatty degeneration, necrosis and liquefaction naturally follow. The lymph spaces, the real absorbents, do the rest. Thus the available material for future cicatricial tissue is reduced to a minimum, with corresponding lessening of future pressure and nerve degeneration.

How may these remedies act in the florid stage of the disease? Simply in the same way, so far as we know, namely, by promoting disappearance of inflammatory accumulations. Few will claim that they actually destroy the germs.

It is conceivable, however, that by stimulating excretion generally by the bowels, kidneys, and skin, they may also promote elimination of a considerable portion of the toxin proper. We should not lose sight of the fact, moreover, that these agents used within proper limits may stimulate the activity of the hemopoetic system, producing a degree of leucocytosis which may be useful in combating the microbes proper. Thus are we relieved of any necessity for a therapeutic nihilism.

In some cases the natural vigor of the patient, assisted by remedies judiciously used and hygienic measures, may apparently exhaust the stock of microbes and the patient remain well of active syphilis at least.

Does this render him secure from degenerative changes? Statistics appear to show that it does not—(Collins[10]). What then may be the cause of such degenerative diseases as locomotor ataxia, paresis, etc.? The hypothesis most in favor at the present day, is that of Strümpell that it is a post-syphilitic toxin, a by-product, so to speak, of the vanished syphilis, which, circulating in the blood, poisons the neuron, but does not excite inflammation. This hypothesis is untenable in the cases, well attested, of locomotor ataxia and paresis, without preceding syphilis. A more plausible explanation, to the present writer at least, lies in the fact of extensive fibroid and hyaline vascular changes, which affect the arteries both in syphilitic and non-syphilitic subjects. (*Vide* Berkley.[7]) The syphilitic toxin, while it must be conceded a frequent cause, is certainly not the only cause of vascular degeneration.

A long-standing and widespread arteriosclerosis or hyaline degeneration is a sufficient factor for the production of degenerative nervous disease, without the intervention, at the time, of any toxin. Thus we may account for many cases of degenerative nervous disease without necessarily invoking the aid of a post-syphilitic toxin, or of syphilis in any form.

Are mercurials and iodids of value in these degenerative nervous diseases? Modern neurological opinion tends to the view that they are not. From what has been said of the modus operandi of these remedies, it is difficult to ascribe to them any virtue in non-inflammatory nervous lesions, where the neurons are undergoing a molecular death from starvation. What good effects are observed from them are in all probability due to collateral influences on secretion and excretion, apart from the nervous degeneration proper.

As collateral at least to the present topic, we may ask. should we withhold mercurials and iodids in a central softening from non-syphilitic thrombosis or hemorrhage? I think not. The fact that these remedies are obnoxious to all newly formed tissue elements, may render them useful in the secondary exudation which always surrounds a gross vascular lesion in the nerve centers. Hence, judiciously used they may limit the amount of organizable material and thus lessen the consequent area of irritation or degeneration in adjoining nerve elements.

It sometimes happens that a patient with extensive cerebral softening, under mercurial treatment, develops a marked rise of temperature. This is not necessarily or even probably mercurial fever in most cases. It would appear to the writer to be due to the rapid breaking down of the necrotic area and the cellular exudate, with the absorption of the debris into the general circulation too rapidly to admit of complete oxidation and excretion. Hence, the pyrexia is more or less septic in origin. It is wise in these cases to omit mercury for a few days and then resume it when the fever subsides.

May vascular disease, widely spread, without foci of gummatous growth, exist as a result of syphilis and give rise to marked nervous manifestations?

The probability is that it may. Berkley[6] has reported two such cases; one with autopsy, in which the chief vascular findings were an extensive and widespread infiltration of the media of the arteries with a hyaline-fibrous material which materially narrowed and in some places even occluded the caliber.

This degenerative change was present in the arteries of the gray matter of the cord, more particularly in those of "Clarke's columns," and in the medulla oblongata; it was also present in the spinal root arteries and in the skin tissues. The writer has under observation a case presenting similar clinical features, in which, however, syphilis can not be traced.

The importance of recognition of this condition when possible lies in the fact that no therapeutic measure known to us has any favorable influence on hyaline vascular degeneration. We may do well to remember, however, that combination of degenerative lesions and inflammation are frequent (Berkley[7]) and that remedies may exert a favorable influence on the inflammatory element.

One more reference to therapy in the light of modern pathology. What have we to look forward to as an improvement upon present modes of treatment? The discovery of an antitoxin serum treatment, similar to that of diphtheria, must be conceded as possible. The arrest, and caseation or cicatrization of gummatous exudates in cases untreated by medicines, as in the one before cited, furnishes us a basis for hope in this direction. The difficulty of transmitting syphilis to the lower animals, which has heretofore hindered experimentation in this direction, will not necessarily always remain unsurmountable.

Neviorovsky[8] has reported favorable results in recent syphilis, from injections of human serum taken from subjects of tertiary syphilis.

Again, remarkable results in two cases have attended the use of Hayem's artificial serum (sodium chlorid 7 gm., crystallized disodic phosphate 2 gm., water 1000 gm.). Half of this was injected every five or six days in addition to mercury and iodids, in cases, which had obstinately resisted the latter remedies alone. The lesions yielded rapidly to the combined treatment.[9]

SUMMARY.

The pathological processes concerned in syphilis of the nervous system comprise:

1. A localized parenchymatous and interstitial neuritis at the site of the initial lesion, due to endarteritis, compression and local toxic action.

2. A localized root neuritis (cranial or spinal), and a peripheral mono-neuritis, both of gummatous type. may occur in the "secondary" stage. A generalized or "multiple" neuritis has been reported, but is so rare as to be a pathological curiosity and open to doubt as to origin.

3. A generalized toxemia affecting the nerve centers directly or metabolism in general and producing febrile reaction of a "specific" type, i. e., "secondary" fever.

4. Inflammatory ("gummatous") lesions, due to disseminated or localized vascular infections. The arterial walls are the chief seat of these gummatous exudations, and the exudate may begin as a "periarteritis," a mesarteritis or an endarteritis, eventually in most cases becoming a "panarteritis"—Berkley. The exudate is always intra-mural—not intra-lumenal—the narrowing of the lumen being due to concentric or nodular thickening of the walls, and heaping up (proliferation) of the deep endothelial layers of the intima. Necrotic changes in the inner layer probably precede thrombosis.

The infecting material (bacteria?) probably reaches the vessel wall via the vasavasorum, from which a portion of the exudate at least is derived. Direct infection of the lining endothelium, by the main blood stream, is unknown and probably does not occur, excepting in the terminal capillary plexuses.

The materials constituting the inflammatory exudate in all forms of gummatous syphilis, whether arteritis, meningitis or tumor are biologically identical, the differences which exist anatomically being due to location and distribution of the exudate. The characteristics of gummatous syphilis of the nervous system are: (*a*), the lesions are primarily vascular; (*b*), the lesions are usually *multiple*; (*c*), the lesions are usually non-systematized in a neurological sense, though they show a predilection for certain localities—namely, the basal meninges, and the arteries of the basal ganglia and motor area; in the cord, the meninges and the ventral horns.

5. Gummatous lesions are, in a measure, self-limited, their growth being checked by: (*a*), central necrosis, due to deficient vascularity; (*b*), the probable development of an antitoxin which checks the local proliferation of microbes; (*c*), fatty degeneration and absorption of the fluid portions with caseation or cicatrization of the remainder.

6. Degenerative nervous processes, due directly to syphilitic exudations, are of two types: (*a*), "compression" degeneration due to prolonged pressure by gummatous masses or their cicatricial sequelæ which separates various neuron processes from the influence of corresponding "trophic centers" (neuron bodies); (*b*) secondary degeneration consequent upon destruction of these same neuron bodies by softening, of thrombotic or hemorrhagic origin. The preceding two types are classed as "non-systematized" degenerations, in contradistinction to:

7. Degenerative diseases, of "systematized" type, such as locomotor ataxia and paresis. These should probably be looked upon as malnutritional affections due in part to arterial degeneration (fibrous or hyaline or both) which may or may not be of syphilitic origin; and in part to inherent individual predisposition to early dissolution of certain physiological systems. These degenerations are not benefited and may be made worse by vigorous anti-syphilitic medication.

8. Remedies of value in syphilis may act in three ways: (*a*), the most usual, by promoting necrosis in the embryonic cells of the exudate, thus permitting their removal in large part by the lymph channels; (*b*), by stimulating the excretory organs generally, thus favoring removal of "toxins" produced by the disease; (*c*), possibly by the promotion of leucocytosis and other tissue changes, which set free an increase of the natural amount of (hypothetical) antitoxin. In no case do these remedies act as "absorbents" or "stimulate the absorbents," nor have we reason to believe that they destroy the microbes of the disease.

9. Any lesion of the nerve centers, attended or followed by inflammatory exudate, whether syphilitic or non-syphilitic, may be favorably influenced by the judicious administration of mercurials and iodids; and subsequent amount of damage by cicatricial compression or irritation be materially lessened.

10. The discovery of a means of producing artificially an antitoxin which shall arrest the disease in an early stage, must be conceded as a possibility.

DISCUSSION ON SYMPOSIUM ON SYPHILIS OF THE BRAIN.

Dr. C. B. Burr, Flint, Mich.—The fact which Dr. Patrick alluded to, in connection with the case mentioned, namely, that the history of infection so many years before caused him to doubt whether syphilis was at the bottom of the symptoms presented, would have led me to the opposite conclusion, inasmuch as in my experience ten or fifteen or more years may elapse after infection before the development of cerebral syphilis. My practice, however, is largely among patients presenting mental disturbance with brain syphilis.

Of cerebral syphilis accompanied by marked disturbances of the mental operations there are two interesting varieties: one in which motor symptoms predominate; the other in which the symptoms are altogether psychical. They are both characterized by reduction. This is their most conspicuous quality. In the one the symptoms are clinically difficult to distinguish from those of paretic dementia. However, there is less apt to be expansive delusions, remissions are more frequent and the disease is of longer duration. In the second variety there is psychical reduction, manifested in dementia, the symptom of lack of memory being the most prominent. There is also hebetude and the patient is dull and unresponsive.

Dr. H. D. Valin, St. Peter, Minn.—I would like to say something about the bacteriology of syphilis. About 1896 an investigator in Baden, Germany, thought he had discovered the bacillus, and he published a pamphlet on the subject. An insane asylum is not a very good place in which to study the bacteriology of syphilis, as in my experience, cases of recent syphilis are rarely encountered there, but I thought I could get some outside cases, and through the courtesy of our late commissioner of lunacy I secured some pus which he assured me came from a syphilitic bubo. This remained for two or three weeks without undergoing any putrefactive changes, which agrees with the statement that has been made that syphilitic pus contains some element which retards putrefaction. Upon examining this pus, I found a small bacillus, staining by Gram's method, which had the characteristics of the bacillus that has been described by Van Niessen. After the pus had been kept for several weeks, increased numbers of this bacillus were found. With this pus I also undertook some inoculation experiments upon animals, and in one of the animals I found three growths in the liver which had the gross appearance of gumma and appeared so upon section.

In another case I was called upon to make a blood analysis by a surgeon not far from St. Peter. This patient had been operated on by another surgeon, who saved the man's life, but the operation left a biliary fistula. In the blood and bile of that patient I found a few small bacilli which were similar to those described by Van Niessen. I found it very difficult to cultivate these bacilli. The work must be done on gelatin. The characteristic changes observed in the gelatin are these: After seven or eight days the upper layer will begin to liquefy, and this will continue until the gelatin is completely liquefied, and at the bottom is a mass of detritus which on staining shows the bacillus. This process of liquefaction also takes place when streptococci are present. Van Niessen states that he found the bacillus even in chronic cases of syphilis of the florid type. In a case of syphilis which came under my observation an examination failed to show any of these bacilli.

Dr. E. G. Carpenter, Columbus, Ohio—There are two points that I have observed in syphilis of the cord and brain. In the first place, in syphilis of the cord, and particularly in those cases where the disease has involved both the brain and the cord, I have noticed atypical reflexes, that is, they were active on one side and absent on the other, with more or less spasticity accompanied by ankle clonus. Another symptom which I have observed, is a slight loss of memory and some degree of dementia, with an accompanying depression sometimes amounting to melancholia. This, in my experience, is rather a common symptom in these cases, and it is in keeping with what we find in other diseases resulting from infection. For example, I have noticed this same symptom of depression in la grippe and typhoid fever.

Dr. John Punton, Kansas City—If the postulate laid down by Dr. Patrick in his paper is true, namely, that the symptoms in connection with cerebral syphilis are apt to present themselves within the first year and gradually decrease in frequency and severity as time goes on, then we must revolutionize our teachings in regard to the symptomatology of cerebral syphilis. From what the Doctor says, however, it would seem that he bases his claims on clinical knowledge. There are one or two points in connection with this subject that have not received sufficient emphasis. One is the temporary remission of symptoms that is not infrequently observed in cerebral syphilis. The patient may apparently be seriously ill on one day, and markedly improved the next.

Dr. Edward E. Mayer, Pittsburg—The postulates set forth by Dr. Patrick may perhaps be a trifle too emphatic, and yet they certainly have a good deal of truth in them. Certainly, his statement regarding the onset of cerebral syphilis and the presence of the initial symptoms agrees with what I tried to say yesterday in the discussion of Dr. Norbury's paper upon paretic dementia. Because syphilis has occurred ten or twenty years before, we should not ascribe to it the cause of the dementia, and the same is true here. In the symposium on syphilis of the brain to which we have listened, the essayists very rightly separated the somatic from the psychical conditions. One symptom to which I desire to call attention is the partial psychic defect. Dr. Patrick ably presented the characteristic features—the bizarre coming and going of symptoms, the progressive dementia; the coma, and the remissions and exacerbations which are so characteristic of brain syphilis.

Dr. Sydney Kuh, Chicago—If there is one thing that is peculiar to the syphilitic psychoses, it is the intermittent and irregular character of the symptoms. One of these intermittent symptoms is perhaps especially characteristic, although it was described nearly fifty years ago; it is almost forgotten to-day. I refer to the symptom which went under the name of the intermittent aphasia of Mauriac. As far as I know, the character of this intermittent aphasia is almost invariably motor. The first attack, which is incomplete and temporary, is followed by a second and more severe attack and the condition finally becomes permanent. Often it is the only symptom. I do not think such a recurrent motor aphasia occurs in any disease excepting in syphilis of nervous system and paralytic dementia.

Perhaps the importance of nocturnal headaches as a symptom of cerebral syphilis is somewhat overestimated. My experience in the last few years has brought under my observation several cases with distinct and severe nocturnal headaches which I had good reason to believe were not of syphilitic origin. In one, the postmortem showed an immense abscess of the lobes of the brain. Very little has been said about the treatment of syphilis, and perhaps it might not be amiss to call attention to one method which in very severe cases has given me most satisfactory results. I refer to the intra-venous injection of corrosive sublimate, as recommended by an Italian writer. The method seems more dangerous than it really is. A local thrombosis may follow the injection, and occasionally there is ulceration; this has occurred in two out of the twelve cases where I have resorted to this method.

Dr. Frank P. Norbury, Jacksonville, Ill.—Dr. Langdon, in his paper, spoke of the fever in syphilis. Some few years ago I observed a case of cerebral syphilis, or rather a case of acute insanity, the victim of syphilis in its secondary stage. During the first six weeks of the patient's stay in the hospital, I noticed a daily elevation of temperature. Whether this was due primarily to the syphilis or not I do not know, but I am inclined to believe that it was, and that the action of syphilitic poison in this case was the direct cause of the acute insanity. Melancholia was the form of mental disease, and I took it that the toxemia was so profound as to disturb nutrition, just as is noticed in typhoid fever, rheumatism and other infectious fevers. He recovered from his insanity and went to Iowa, where he subsequently resided. One day, eighteen months after leaving the hospital, he fell while walking along the street, and was picked up unconscious. He died in the course of a few days, and his death was attributed to some acute brain trouble.

Dr. Dewey, in reply—I do not know that I have anything more to say, unless it may be to give the periods of time that elapsed in my cases between the syphilitic infection and the onset of the insanity. In one case the insanity followed the infection within two years; in two, within three years; in three, within six years; in four, within seven years; in three, within eight years; in two, within nine years; in one, within ten years; in one, within twelve years; in four, within fifteen years, and in one, within sixteen years. In one, where nineteen years had elapsed since the syphilitic infection, the possibility of a second infection was thought of. This was the case of a religious brother who had been engaged in his priestly work for twenty years. He frankly acknowledged that he had been infected previous to that time, but the circumstances were such that a second infection could scarcely have occurred.

The symptom of loss of memory, to which one of the speakers referred, can not always be regarded as diagnostic of cerebral syphilis. It may be due to other causes. With reference to the intra-muscular use of bichlorid solution, I had a patient upon whom this method of treatment was employed. He thought the hypodermic injection was given to him for sedative purposes, and regularly fell asleep soon after administration.

Dr. Langdon, in reply—The suggestions made by Dr. Kuh were referred to in that portion of my paper which I did not get an opportunity to read. I mentioned the fact there that in the treatment of syphilis several improvements upon our present methods have been suggested by various writers. Among these is a Russian who in two or three very obstinate cases has employed an antitoxin with very favorable results. The antitoxin is obtained from the serum of old syphilitic patients, and is given by hypodermic injection.

PREVENTABLE DISEASE IN THE ARMY OF THE UNITED STATES—CAUSE, EFFECT AND REMEDY.*

MAJOR W. O. OWEN, M.D.
FORT THOMAS, KY.

Owing to the fact that my ideas, as expressed in a pamphlet that I had printed for private circulation, have appeared in part in the public press; and fearing that some one may be misled as to my intention and thought, I have concluded that it were better to express myself as fully as I can to the Academy of Medicine of Cincinnati and through it to the profession at large. I had no thought of making an attack upon any individual and therefore carefully abstained from using the name of any officer where possible offense might be taken My aim was to call the attention of my professional brothers to a state of affairs which appeared to me was costing the Government large sums of money and the soldier great and unnecessary suffering from preventable disease, to call attention to the fact that the Red Cross of the Geneva Convention, which was intended to protect the surgeon, was actually a menace to his personal safety, for he was unwittingly using it to protect property which belonged to the fighting force and was only loaned to the hospitals for temporary use. To ask you if you felt that you could agree with the position which I have taken that you put your shoulder to the wheel and help me to see if we could not as a body be able to create a public sentiment which in the future would lead to the correction of this, which I believe to be a wrong inflicted on the soldiers of all armies. I have seen in print that many medical men were sacrificed to save the military officer in the Crimea from the public clamor. Has not similar matter happened in the United States?

---

* Read before the Cincinnati Academy of Medicine, Oct. 7. For discussion, see p. 1130.

There occurred from May, 1898, to June, 1899, in the armies of the United States, deaths from: diarrhea and dysentery, 342; typhoid fever, 2774; homicide, suicide, and gunshot wounds, 1020. Out of a total death of 6619: diarrhea, dysentery, and typhoid fever, 3116; homicide, suicide, and gunshot wounds, 1020. This is slightly more than three deaths from these well-known preventable diseases to one of homicide, suicide, and gunshot wounds. (See Table VII, page 349, Report of the Surgeon-General United States Army to the Secretary of War, 1899). It will be noticed that this includes the battle casualties of Cuba, Porto Rico and the Philippines to June, 1899. Was this loss an imperative military necessity?

I believe that the day has come when all sanitary matters of the army should be placed under the control of the Army Medical Department for the reasons:

1. That by so doing very large economies may be made in the maintenance of the army, both in money to the United States and in suffering to the individual soldier.

2. To enable the Army Medical Department to obtain the immunity guaranteed by international treaty, which at present is not fully done.

Under the first head I would call attention to the fact that nowhere in statute law are the duties of the army medical man laid down except in one place, which says that he shall attend to the families of officers and men free; and in one other, that the Secretary of War may assign him to such duties as he may deem for the best interests of the service: *"Provided,* that the medical officers of the army and contract surgeons shall, whenever practicable, attend the families of officers and soldiers free of charge." (Supplement Revised Statutes United States, Chapter 217, Paragraph 6, Vol. I, p. 457.) "That medical officers of the army may be assigned by the Secretary of War to such duties as the interests of the service may demand." (Supplement Revised Statutes United States, Vol. II, Chapter 270, Section 3, p. 53.) The opinion expressed by a medical officer that a man has defects that disqualify him for service as a soldier is not final; it is a common thing for these men to be accepted by special authority, the defects being noted on the enlistment papers.

There is no regulation, so far as I know, and I think that I know, which requires an officer in charge of construction to submit the plans of construction to the Medical Department for an expression of an opinion as to the sanitary results before beginning the construction. The result is that every post at which I have served, even the most modern, is full of sanitary error that has cost much money to correct, when it has been corrected. Much disease has been the result.

In the annual reports of the Surgeon-General will be found each year accounts of many faults of sanitation which have been reported in the preceding twelve months. Each of these faults could have been prevented by proper medical advice at the time when the original construction was being made. When examining these reports it should be borne in mind that attention is only called to the more glaring instances which have been brought before the office and that the mass is too great to be placed in an annual report.

All that the Medical Department can do is for its individual members to report errors and recommend their correction. It is only a courtesy when the commanding officer listens to his medical officer. He is compelled by regulation to listen, but he is given the expressed right not to carry out the recommendation made by his medical officer for the prevention of disease amongst his men. In other words, he is given, by regulation, control over matter of which he has no adequate knowledge, as witness the following:

> 1392. The Medical Department, under the direction of the Secretary of War, is charged with the duty of investigating the sanitary condition of the army and making recommendations in reference thereto, with the duty of caring for the sick and wounded, making physical examination of officers and enlisted men, and furnishing all medical and hospital supplies, except for public animals.
>
> 1393. The surgeon, under the direction of the commanding officer, will supervise the hygiene of the post or command, and recommend such measures as he may deem necessary to prevent or diminish disease. He will examine, at least once a month, and note in the medical history of the post the sanitary condition of all public buildings, the drainage, the sewerage, amount and quality of the water supply, the clothing and habits of the men, and character and cooking of the food, and immediately after such examination will report thereon in writing to the commanding officer, with such recommendations as he may deem proper. The commanding officer will return the report, with his views and action indorsed thereon, and if he deem the action recommended impracticable or undesirable; will state fully his objections. The indorsement will be recorded in the medical history of the post, and the report and indorsement will be forwarded by the surgeon, through military channels, to the Surgeon-General. (Army Regulations, 1895, 1392-93.)

Constant changes are being made in posts by the quartermaster affecting sanitation. The surgeon, supposedly in charge of sanitation, finds or may not find them out before some one is dangerously ill or dead. If not before the disease has arisen, a search is then made, and reveals new and dangerous changes made in work previously inspected and found to be in good shape. Should he ask about it, he will be informed that these changes were made by the quartermaster whose business it is to look after construction.

At Fort ———— each company has ten wash basins, arranged in two gangs of five each, one gang on each side of the common trap and vent. This is a violation of the rules for plumbing issued from the Quartermaster's Department in Washington, D. C. It is also a violation of the plumbing rules of all of the large cities.

In time of war military necessity must control, but every precaution both in peace and war, but particularly in war, should be taken to put the soldier upon the highest plane of physical and mental excellence, so that he may be able to reach the highest efficiency as a fighting machine. Yet I have seen men drilled morning after morning in dew-laden grass until they were wet to the knee; have seen them living in overcrowded barracks, making a large sick report without actual necessity, etc., and the medical officer powerless to do aught but recommend.

Take the report of Lieut.-Col. A. S. Kimball, Quartermaster's Department, on the water supply of the Presidio, Cal. (See Report Surgeon-General United States Army to the Secretary of War, 1896, *pp.* 137-38). His report shows a water of undoubted high quality. He has based his report on the analysis made by Thomas Price & Son.

It is evident that these chemists were not informed as to the character of the water-shed from which this water is obtained. Mountain Lake, from borings around which this water is obtained, has a water-shed of two *and one-half to three square miles*; it is composed of seashore sand resting on a bed of rock. In this water-shed are three of the largest cemeteries of the city of San Francisco. A very large part of this water-shed is a closely-built city, with sewered streets, which sewers have uncemented brick bottoms. There are many animals stabled in it; all of the fecal matters of these animals and of this population is stored in this water-*shed; all of the products of the decomposition of the* bodies buried in these three graveyards drain into it; all of the excrement and kitchen waste of old Camp Merritt were buried in it. (There were some 18,000 men camped in this camp.) So long as the sand retains its ability to filter properly the water will be safe; when it becomes saturated with filth the health of the soldier at the Presidio will suffer. The water level of this lake has been lowered some twenty feet since the pumps have been at work. The officers of the Marine-Hospital Service tell me that they are afraid to use this *lake water without first subjecting it to sixty* pounds of steam. I made a careful chemical analysis of this water in 1899, and a careful personal inspection of this water-shed; *it was self-evident that there must be contamination* from animal source.

I believe that the analysis of Price & Son was correct when made; that the differences that exist between us are due to changes which have taken place from the *increased number of bodies in the water-shed, from the* increase in the population within the water-shed; that with these two causes that the sand is more soiled, and *therefore no longer filters so well as formerly.* It is a well-known fact that when sand is well aërated and not overloaded that it will filter out from 98 to 99.5 per cent. of all the germinal matter present.

Point Lobos Creek is the natural drainage channel of this water-shed. I was informed in the office of the Spring Valley Water Company that it had been formerly in use as a water supply for the city of San Francisco but that it had been abandoned for such use as it was too polluted.

The Presidio, with a water supply from this water-shed, was especially chosen as a model camp in which to assemble the troops for Philippine service, and the muster out of the returning volunteers.

Gen. ———————, in his testimony before the war investigating commission, says in effect that he did not listen to his chief surgeon as to the medical needs of those commands that were to be detached from him; that he took from others and gave to his personal corps medical material on requisition that his chief surgeon had disapproved; that he compelled his chief surgeon to personally look after a division hospital instead of al*lowing him to look after the larger duties of his position*; that he himself, in his own person, set the example of defying the recommendation of his Medical Department in drinking from a well that he was informed that the Medical Department had said was unsafe to use, and that he permitted the broken pump to be repaired so that the well might still be used. (See pp. 3080-81-85-86, Commission's Report, War with Spain.)

The general in a letter dated Nov. 12, 1898, uses the following language concerning his chief surgeon: "In the matter of the location of the troops in the camp, Col. ——————— was not consulted, so far as my recollection goes, nor did I deem it necessary to consult him: there was no need of it. Any 'protest' he made received such attention as the importance of it required."

The report of Reed, Vaughn, and Shakespeare says:

> Some regiments at ————, as we have shown, were so located that they received the drainage of other regimental camps. There was certainly no sufficient excuse for this. . . The —th Indiana was forced to contract its lines to half the regulation distance, and it was then only 30 feet distant from the —th Ohio. The sinks of the last-mentioned regiment and the kitchens of the —st West Virginia were only 12 or 15 feet apart." . . . (The —th Penn.). This command reached —— May 20, and was unfortunately located on low ground. Requests for a change of location were repeatedly made in June and July. The soil became muddy; the camp received the washings from the other camps above; the sinks rapidly filled with water and overflowed, and still requests for a change in location were unheeded until August 12.
>
> As we have already seen, some regiments were improperly located from a sanitary standpoint. This was done by superior line officers, and sometimes in the face of protests from the medical officers. We have also seen that requests for a change in location were disregarded and regiments were allowed *to occupy one site for too long a time. In general the camps* became very filthy. It must be therefore admitted, it appears to us, that line officers were to some extent responsible for the conditions of the camps under their command. The medical officer can only recommend; the line officer can command.

Again the letter of the general continues: "Col. ———————'s impression of the water was not borne out by the analysis of it." Of this command 21.56 *per cent. suffered with typhoid fever, and* 714 men died of this disease in this camp.

What opportunity have sanitary officers to have their recommendations carried out; what opportunity to prevent disease, when the general in command treats his chief surgeon with disrespect both as to his person and as to his recommendation; when the general himself drinks a water that he is informed has been condemned by the sanitary officer? In another place, when the general has read to him a report made by a sanitary officer concerning this camp, he requested that he might be given a copy of the report, so that he might bring the reporter to trial before a general court martial. He was informed that it was not protected testimony, and where a copy could be had. His further action is not known.

The mortality of the Spanish-American war was 28 per 1000 living. The mortality of men in civil life, including the lame, halt, and the blind, is about 8 per 1000 living between 20 and 35, the age limit of the armies of the United States. The enlisted soldier of the army of the United States is selected carefully from the flower of young American manhood. Young men physically sound between 20 and 35, with proper sanitary care, should not have a mortality of more than 1 or 2 per 1000 per annum; excess over this means careless sanitary work, and 28 per 1000, which was the average of the Spanish-American war, means that the work was badly done in these camps, and that more than four-fifths of these diseases and deaths should have been prevented; they were not a military necessity, for no enemy was near. These lives should not have been taken; their mothers, wives and sisters should not have been thus grieved; the Government should have been spared this loss of life, and the loss of money needed to replace the dead and disabled, to pension the widows and dependents of the dead and to pension the disabled.

So far there has been allowed 6000 pension claims for the Spanish-American war; 44,000 claims are still to be adjusted. One to seven so far has been the average allowed; if these receive $100 per annum (the average for June, 1900, was $169.10) and the ratio holds, it means that the annual pensions for this war at present amount to $1,200,000, or the interest at 3 per cent. on $40,000,000.

Fully two-thirds of this list should have been saved by avoiding pensions to men disabled by preventable disease. These men are now disabled or dead; they, their widows and dependents, are to be cared for by the Government. How much better to have so cared for them that they had been returned to the bread-winners of the country! The normal death-rate of times of peace is largely increased in war times, not from injury, as many suppose, but from disease. These diseases are not so much from marching and maneuvering for battle position, but to the insanitary conditions of the camps, which, under a proper responsibility before the law of the land, can be easily corrected.

Look at the testimony given before the commission to investigate the Spanish-American war concerning Camp Alger, Fall's Church, Va.; concerning Camp Thomas, Chickamauga, Ga., with their pollutions of every possible class. The loss of life in these camps was more than forty times the corresponding loss in the city of Cincinnati, and one hundred times that of the City of New York (see "Purification of Public Water Supplies," J. W. Hill, p. 268).

The law should be so drawn that, without depriving the line officers of their proper military authority, yet it should fix definitely on whom this responsibility for the death and disability of the soldier by preventable disease rested; should fix when and under what conditions the Medical Department or the Line is responsible, or to fix it permanently on the one or the other. The law should fix the responsibility in order that some one man may be punished for the violation of established sanitary law.

No man, seeing before him the absolute certainty of having to account to the law, with his own body and reputation, for the loss of life, and for disease arising from his carelessness, lack of knowledge, lack of what not, will hesitate to apply the legal remedy and thus keep from his own shoulders the responsibility.

The saving to an army in suffering, to its individual men, to the Government in money paid in pensions, to the dependents of the dead, the disabled, and to men to replace the dead and disabled on the active lists is simply incalculable.

The cost to the individual soldier in suffering has been great from a lack of proper sanitary care. A careful examination of the medical histories of wars will show any man, who has made sanitation a study, what huge costs governments pay for a lack of sanitary law for their armies, and a fixing therein of the individual upon whom shall rest the responsibility for a breach of the sanitary law. Any military commander committing a military blunder which sacrifices his army is punished, but they are allowed to sacrifice men without number to insanitary conditions without question, without a word of condemnation, or even a thought of so doing.

TRANSPORTATION.

The other point to which I wish to call attention is the International Treaty, the so-called Geneva Convention, to which the United States is a party. This provides that all of the transportation and supplies of the Medical Department which go with the moving army, under its terms called "ambulances" (See Additional Articles, Article III, Geneva Convention), are exempt from capture and from being fired upon.

The greater part of these are under the control of the Line, and belong to the Quartermaster's Department, and are accounted for to this department. This condition makes all of this transportation liable to capture, and to be fired upon by the enemy, for they are unable to distinguish the transportation of the Medical Department (exempt) from that of the Quartermaster (non-exempt). This leaves medical transportation exposed to capture, etc., because unprotected by the International Treaty. (The Act of March 11, 1864, gives strict orders about ambulances, etc. The United States became a party to the Geneva Convention in 1882.)

The transportation of the Medical Department and many medical supplies were left at Tampa, Fla., by orders of the line officer when the army went to Cuba in 1898. The Surgeon-General should have had authority, and then he would have had the proper ship on hand, and would have moved all of his supplies and transportation on his own ship at the same time that the troops moved, and he would have had his material and transportation ready to disembark at the same time that the troops disembarked, and would have prevented the suffering that took place for the lack of this material and transportation when the fights took place. As it was, the comparatively small amount of material which the chief surgeon was able to take with the expedition was scattered throughout all of the ships of the expedition; he was compelled to devote much of his own time and that of other officers to try to get such portions of this medical property as was possible from the mixed mass of quartermaster, ordinance, commissary, and medical stores on board of these ships, instead of being able to attend to the proper distribution of both officers and supplies of his department.

The report of Captain E. L. Munson, Assistant-Surgeon, U. S. A., shows the exceeding difficulty which the medical department encountered in getting proper transportation for their supplies, showing that after much worry he obtained a four-oared boat, which was taken away from him after a few hours.

Should a field hospital be captured under present conditions, the first question by the enemy would be: "To what department does this material belong? Can the Line of your army take any of this material from the Medical Department and convert it to its own use, or is it exclusively for the use of the Medical Department?" The answer by our medical officer of necessity must be that "the axes, stoves, cooking utensils, hospital tents and all other tents, hospital flags and guidons, horse equipments, wagons, ambulances, mules, and horses, one and all belong to the Quartermaster's Department; that they were liable at any time to be taken by the Line, used by them for fighting purposes, and that the Line was the sole judge of when and for what reason this was to be done."

The enemy will very properly say that "you are sailing under false colors. We have no time for fine distinctions. We will take the whole outfit." Yet the medical officer is ordered to go into the field with this transportation, which belongs to the fighting force and to protect it by flying the Red Cross flag of the Geneva Convention over it until such time as the fighting force may need it. It is a clear violation of this treaty to place in the field hospital (ambulance) material belonging to the fighting force. Yet in the armies of the United States the "ambulances" are composed of material which the Line is obligated to take from the use of the sick and wounded whenever its needs require that they should do so, for not even the hospital flag or hospital tent is the property of the Medical Department. In fact all the wagons, horses, tents, etc., which go to form an "ambulance" belongs to the fighting force, and it is only loaned to the Medical Department until such time as the fighting force needs it again.

The word "ambulance" is ordinarily used to express the idea of a wagon so prepared that it will carry a sick or wounded man comfortably. This word, however, when used in the Geneva Convention is given a distinct and very much enlarged meaning. For the 3d Article of the additional articles gives to it the meaning of a field hospital or other temporary establishment which follows the troops on the field of battle to receive the sick and wounded. Hence, our English cousins and many others say "ambulance wagon," which translates into the vernacular as "hospital wagon."

It was the evident intention of the Geneva Convention to protect the sick and wounded. The ambulance wagon, the so-called Red Cross wagon or ambulance, because it is marked with the red cross of this convention, should certainly not be the only part of the field hospital which is protected from being fired on and from capture. The four and six horse wagons, the tentage, beds, bedding, and food are just as necessary to the care of the field hospital, and is, in fact, a part of it. The ambulance brings the patient to the hospital, the wagons move the tentage, etc., from place to place; as the command moves the ambulance wagon moves the patient, the wagons move the hospital. So long as the transportation of the Medical Department belongs to the Quartermaster and is only loaned for temporary use to the Medical Department, will the Line have the right—in fact, the obligation—to take it from the use of the disabled and convert it to the use of the fighting force, when they deem it necessary. What line officer will hesitate for a moment to take the mules from the Red Cross ambulance itself and send them for ammunition, should he be hard pressed and others not available. They do not bear the Red Cross. Certainly they will not hesitate to use a wagon marked Q. M. D., U. S. Army. This will enable the enemy to comply with the Geneva Convention and strip the hospital of everything that is likely to afterward be of use to the fighting force. The Line can at its own volition take quartermaster's property away from the Medical Department.

GENEVA CONVENTION—ORIGINAL ARTICLES.

Article I.—Ambulances and military hospitals shall be acknowledged to be neuter, and as such shall be protected and respected by belligerents so long as any sick or wounded may be therein. Such neutrality shall cease if the ambulances or hospitals should be held by a military force.

Article IV.—As the equipment of military hospitals remains subject to the laws of war, persons attached to such hospitals cannot, in withdrawing, carry away any articles but such as are their private property. Under the same circumstances an ambulance shall, on the contrary, retain its equipment.

ADDITIONAL ARTICLES.

Article III.—Under the conditions provided for in Articles I and IV of the convention, the name "ambulance" applies to field hospitals and other temporary establishments, which follow the troops on the field of battle to receive the sick and wounded.

What are the laws of war concerning the misuse of this protection?

RESPONSIBILITY.

The appended bill does not take command from the Line; but it does compel them to assume the responsibility for insanitary conditions which may arise when they choose to ignore the sanitary recommendations made to them by the Medical Department, when they do so without proper military reason for their action, and it does provide a legal remedy whereby the officer responsible may be reached by proper legal process. To assume the responsibility with proper military reason is a thing that the Line should at all times have the right to assume. In such camps as Camp Thomas, Ga., there were strong reasons to carry out sanitary law and none to ignore them.

On page 2981-83 of the report of the commission to investigate the war with Spain, Col. Hartsuff (the chief surgeon at Camp Thomas, Ga.), testified that he personally reported to the General in command that one of the camps was "outrageously foul; that it was an imperative necessity that this camp be broken up at once; that there are large numbers of typhoid fever cases in each regiment." His letter was dated July 11. 1898. On page 2983 he testifies:

Question: "Practically, then, all the recommendations that you made were simply paper manifestoes?"

Answer: "In most cases; yes, sir."

On page 3080 the General in command testifies:

Question: "Had any of the wells, General, been condemned by the Medical Department prior to your leaving the department?"

Answer: "By alleged Medical Departments? Two of them were erroneous, I believe, after examination into it myself. . . . Another well lying on the road between the Alexander House and Jay's Mill was also condemned. I drank of that well water every time I passed it until somebody broke the pump to pieces. I suppose it was some of our energetic medical fraternity, who had spent their time in finding that there was a suspicion of these two wells, and then I did not bother further about it."

Either the medical officer or the officer in command was at fault. Unfortunately, there is no fixed responsibility before the law for either the one or the other, and so it is that no one is punished for this most culpable state of affairs, except the helpless soldier, whose love of country leads him to an inglorious death and a premature grave by diarrhea or dysentery, a death as useless as it is preventable and expensive to the United States.

The question, plainly put, is, How many men lost their lives in 1898-99 from the incompetency of the commanding officer, or of the medical officer? Of the officer who was to judge of the necessity of carrying out the recommendation made or of the officer whose duty it was to recommend? It must perforce lie between the two.

Army Regulations, 1895, paragraphs 1392-93, make the medical officer responsible for recommendations, but gives none to the commanding officer for not carrying out the recommendations made, but gives him the expressed right not to do so.

No medical man will continue to recommend when he sees his recommendation treated with good-natured indifference, or worse, for by so doing he lessens the influence that he may have; he does, however, continue to talk to the commanding officer and try to influence him in the right direction in spite of the indifference with which he is met. The medical officer is compelled to obtain what he can in a sanitary way by means of placation and persuasion.

In answer to the above there will be many responses, which, when sifted, simply mean that those in command are unwilling to assume responsibilities for matters which they do not understand; that they feel that they must have absolute and entire control of everything in the army, both in peace and war; otherwise the victory is not to be won, etc.; that no man should be allowed to tell them how to take care of the men; that they have done so in the past and that they can do so in the future.

If the medical man in the army is not competent for the responsibilities above sought, the sooner that he is removed and replaced by competent men from civil life the better for all concerned. It is far more important that the medical man should have ability to prevent the ingress of disease into a command than to be able to treat it after it has arisen.

Command has grave responsibilities. In order that it may be effective it must have absolute and unquestioned control of men and material present. Among these responsibilities is that for insanitary conditions that may arise. Line officers are not trained sanitarians, medical officers are. Under the present law neither is responsible. All errors are charged to military necessity, unfortunate, but non-preventable.

The Omniscient has established a law governing the life of the typhoid bacillus as certainly as he has fixed the path for the several planets. The law of germ disease and the law of sanitation, while certain, are delicate and difficult of comprehension and require years of study to comprehend even in degree.

The layman of the highest intelligence does not comprehend the full relation of cause and effect in matters of sanitation, or in the transplantation, growth and destructive effect of the typhoid bacillus without long study. He prefers to call to his own family an expert physician when his wife or child is sick, and he takes expert advice; but when he is an officer of the Line he sometimes—nay, often—regards such advice as an invasion of his superior authority, and disposes of it by writing across the written advice of the expert employed by the Government, the report and recommendation of the medical officer, "Not concurred in," which disposes of the matter.

It is a breach of military discipline to undertake to argue with the commanding officer or to instruct him in sanitary care, or even as to the habits of the typhoid bacillus. Thus soldiers die, are disabled, and huge sums are paid for pensions which could have been avoided. Is it not best to leave sanitary matters in the hands of medical men? Is it wise to leave them in the hands of the Line officer? I have conceived the idea that the purpose of Congress in creating the Medical Department of the United States army was that the Medical Department should direct such measures as would give the General, when he offered or was to receive battle, the greatest number of men in the best physical condition, and to watch over the men that the smallest amount of disease may arise, so that the greatest number may be returned to their homes fit to earn the living for the family when the war is finished, and that the fewest be compelled to accept the provisions of the pension law.

In other words, if the medical officer is to take care solely of the sick and wounded, and the Line officer is to look after the sanitary condition of the camps, barracks and troops, then the most valuable part of the medical officer's knowledge is lost. Certainly his best work is done in preventing disease, and not in caring for it after it has arisen from insanitary conditions imposed by the imperfect knowledge of the Line. To put it another way, there are many medical officers who wish far more strongly for the power to enable them to control disease than for any increased rank that may be given them. Certain it is that the people should dread a war far more for the preventable diseases that may arise than for injuries that may result, and perhaps more still for the taxes for pensions due to such cause.

Compare anywhere the sanitary conditions which exist where the Medical Department controls and where it recommends. Compare the hospitals in the city of Manila with the barracks of the troops of that city. Compare the hospitals where the Medical Department has the command and where it is subjected to the command of a Line officer.

The most important thing to be brought out is, that neither the commanding officer nor the medical officer is responsible under the present law and regulation for insanitary conditions which may arise with the resultant diseases and deaths, that this condition is a great wrong to the soldier and that it should be corrected by law. Neither the commanding officer nor the medical officer can be punished under the present law and regulations. It is my firm conviction that when a man causes the loss of another man's life, by inattention to his duty, or by faulty judgment of what his duty was, that there should be some legal process by which to punish him for his inattention, or to remove him for his lack of correct judgment. Under the present law and regulation the cry is the same old cry which sacrificed the medical man in the Crimean war. The general saying that the medical officer did not inform him of the conditions, that he did not make the proper recommendations, that he himself had made careful daily inspections, that he did not see the conditions complained of; therefore, he could not issue the orders to prevent things that he did not know of. The medical officer answers that he did report day by day to the general, that he made the recommendations, that he foretold that which happened, that the general thought that it was best to let matters take their course. Both claim that the other is responsible and the public can not know which truly is. This very plea was made before the war investigating commission in 1898, when the question was up as to who was responsible for the great spread of typhoid fever and the unnecessary loss of life therefrom. There should be a code of punishment provided for those actions which lead to the death of men from preventable disease without military necessity.

RESULTS.

The results of such regulation were plainly visible at Camp Thomas, Ga., at Camp Alger, Va., and other camps of assembly in 1898-99. Numbers of men lost their lives through some one's fault. Has the responsibility been fixed? No! It is impossible to fix the responsibility under the present law and regulation. Such things should not be allowed in this day. The responsibility should be fixed on the medical officer, who is trained for this work, or it should be fixed on the Line, and it should be fixed by law. The principal thing is to fix the responsibility either on the Line or the Medical Department, but fix it so that it may not be evaded by any possible excuse, except that of military necessity in the face of the enemy.

The place *par excellence* to see the effect of this lack of law will be a classified list of the diseases and injuries for which pension has been granted, both for the Civil war and that of 1898-99. and a classified list of the claims yet to be adjusted. Take these lists to any man who is a sanitarian and ask him what percentage of the disease represented on the lists could have been prevented by a proper sanitary care, what percentage with good sanitary care would have left no permanent disability.

There is no man more earnestly in favor of the pension law than I am, but I do feel that it is far better to so treat the soldier that when the war is over he will return home in good physical and mental condition. To so return all but the killed and wounded would be perfection.

I do not wish to imply that the pension rolls have men improperly on them, but I do wish most emphatically to state that had the Medical Department had the power to control in sanitary matters a very large proportion of the deaths and disabilities from disease could have been prevented, and would have been.

The Line officer should have the power of command over his troops, but when he refuses to correct sanitary errors he should have a controlling and imperative strategical reason for his refusal. He should not be allowed to subject his command to insanitary conditions in time of peace, nor in time of war, knowingly, unless there be imperative strategic reason, which he could offer to his superior as a proper defense.

No good business man employs non-experts to supervise experts.

It is my belief that the army medical corps, as a body, cares more for the power to do its full duty to the army than it does for any increased rank or pay. In order to do its full duty to the army it must control in sanitary matters.

At present its sole function is advice and recommendation; its only power the mental strength of its individual officer, who sees the sanitary error, and his ability to persuade commanding officer to correct it.

The following table is taken from an abstract of the report of Reed, Vaughn and Shakespeare, on the origin and spread of typhoid fever in the military camps of the United States in the Spanish war in 1898, p. 193:

Command, Etc.	Number of Regiments.	Mean Strength.	Cases of Typhoid Fever.		Deaths from Typhoid.	Deaths from all Diseases
			Certain.	Certain and probable.		
1st Army Corps (Chickamauga)	22	27,380	2,912	5,921	344	397
3d Army Corps (Chickamauga)	17	20,568	1,741	4,418	417	469
4th Army Corps (Chickamauga).	7	7,507	440	1.498	99	112

Total number of deaths from typhoid fever in the 17 regiments of this corps (p. 33)	417
Aggregate strength of the 1st and 3d Army Corps, excluding the regiments that went to Porto Rico from the 1st Division, 1st Army Corps, the 1st South Carolina, from the 3d Division of the 1st Army Corps and the 1st District of Columbia Volunteers from 1st Division, 3d Army Corps (p. 57)	44,803
Total number of probable cases of typhoid fever among these troops (p. 57)	9,660
Percentage of probable typhoid fever among these troops (p. 57)	21.56
Total number of deaths from typhoid fever among these troops (p. 57)	714

Mortality per 100,000 living from typhoid fever was as follows: First Army Corps, 1749; Third Army Corps, 2146.

J. W. Hill, "Purification Public Water Supplies," pp. 268-71, gives the following death-rate for typhoid fever: New York, 21; Chicago, 83; Philadelphia, 64; Cincinnati, 67; The Hague, Holland, 3; Cairo, Egypt, 260.

The above is calculated on all living in the cities; those for the army corps are for men in the prime of life, from 21 to 35, selected after a careful physical examination (see enlistment papers in the Adjutant-General's office, Washington, D. C.).

Notter and Firth, "Theory and Practice of Hygiene," published by Blakiston & Son, 1896, p. 772, gives the annual death-rate per 1000 living males for age groups:

Age group.	1871-80	1881-90	1891-93
20-25.	7.4	5.7	5.4
25-35	9.4	7.8	7.4

Translating this to 100,000 living makes:

20-25	740	570	540
25-35	940	780	740

Death-rate per 100,000 living from typhoid fever alone in the army, the physical condition of the men vouched for at enlistment as sound, was as follows: First Army Corps, 1749; Third Army Corps, 2146.

On page 779 of Notter and Firth is given the following as the death-rate from typhoid fever per 1000 living in England and Wales:

1884	0.236	1889	0.176
1885	0 175	1890	0.179
1886	0 184	1891	0.168
1887	0.185	1892	0 137
1888	0 172	1893	0 229

The following, showing the annual mortality from several sources per million persons living at all ages in successive periods and years, is taken from "Vital Statistics," by Arthur Newsholme, published by Swan. Sonnenschein & Co., London, 1899, p. 320:

	1861-70	1871-81	1881-90	1891-95
Typhus	885	57	14	4
Enteric (typhoid)		322	196	174
Ill defined		103	25	8

The following table ("Vital Statistics," p. 203) shows the attack-rate and death-rate per 100,000 living from typhoid fever for the entire population of the city of London at each age period in 1896 for the two sexes:

All ages.	Attack rate—Males.	Death rate—Males.
20	117	26
25	107	22
35	60	19

The report of Reed, Vaughn and Shakespeare, p. 94, gives the following data for Second Corps:

	Attack rate—Males	Death rate—Males.
1st and 3d Army Corps, 1898	21,560	1,947
2d Army Corps, 1898	11,238	1,070

The mortality for the First and Third Corps together is about ninety-two times the corresponding loss in the city of New York, and twenty-eight times that of the city of Cincinnati, Ohio. The entire male population is included in the calculation for the cities. The First and Third Corps were men picked carefully for physical soundness less than six months previously. The attack-rate was about 184 times that of the city of London for 1896. The General in command of the Second Army Corps, in his testimony before the investigation commission, pp. 233-234, said: "I believe that the water, when it came from the wells, was as pure as when filtered; in other words, I would rather drink the water that came from the wells but I, of course, subordinated my opinions in those matters to my medical officers."

The General in command of the First and Third Corps says in his testimony, p. 3080, speaking of the water at Camp Thomas, Ga.: "Another well lying on the road between the Alexander House and Jay's Mill was also condemned. I drank of that well water every time I passed it until somebody broke the pump to pieces. I suppose it was some of our energetic medical fraternity who had spent their time in finding that there was a suspicion of these two wells."

Among the conclusions of Reed, Vaughn and Shakespeare are the following (pp. 178-188):

13. Typhoid fever is more likely to become epidemic in camps than in civil life, because of the greater difficulty of disposing of the excretions from the human body.

14. A man infected with typhoid fever may scatter the infection in every latrine in a regiment before the disease is recognized in himself.

15. Camp pollution was the greatest sin committed by the troops in 1898.

18. Many commands were allowed to remain on one site too long.

19. Requests for change in location made by medical officers were not always granted.

20. Superior line officers cannot be held altogether blameless for the unsanitary conditions of the camps.

As we have already seen, some of the regiments were improperly located from a sanitary standpoint. This was done by superior line officers, and sometimes in the face of protests from the medical officers. We have also seen that requests for change in location were disregarded, and regiments were allowed to occupy one site for too long a time. In general, the camps became very filthy. It must therefore be admitted, it appears to us, that line officers were to some extent responsible for the condition of the camps under their command. The medical officer can only recommend, the line officer can command.

21. Greater authority should be given medical officers in questions relating to the hygiene of camps.

In our opinion, it is of the greatest importance that more authority be granted medical officers in all matters pertaining to the hygiene of camps.

22. It may be stated in a general way that the number of cases of typhoid fever in the different camps varied with the methods of disposing of the excretions.

42. The continued fever that prevailed among the soldiers in this country in 1898 was typhoid fever.

At the second session of the Fifty-Sixth Congress, December 6. 1900, Mr. Hay introduced in the House of Representatives the following bill, which was referred to the Committee on Military Affairs and ordered to be printed:

A BILL.

To define the duties of the Medical Department of the Army of the United States.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the duties of the Medical Department of the army of the United States shall be as follows:

1. The direction of measures for the prevention of the ingress of disease among the troops of the army and of sanitary faults in location, construction (and management) of posts and camps.

2. The medical and surgical care of diseased and injured officers and soldiers of the army of the United States; the physical examination of all officers and soldiers entering or leaving the army of the United States.

3. The care (of) and accountability for all transportation pertaining to the movement of men and supplies of the Medical Department and (of) the sick and injured of the army.

4. The preparation and preservation of the records of transactions taking place under the three preceding paragraphs.

5. It shall be the duty of the senior medical officer of the (army), corps, division, or brigade (territorial division or department), in which an unusual outbreak of disease shall have arisen to at once take steps to investigate and determine the reasons therefor.

Should this investigation show any carelessness or inattention to duty, either upon the part of the medical officer or of the officer in command at the infected point, he shall at once make report (of the facts) to the officer in command (of the army, corps, division, or brigade, territorial division, or department), whose duty it shall then become to bring the offending officer or officers before a court-martial for such punishment as, upon conviction, the court may deem proper and the reviewing authority concur in.

6. The Secretary of War is hereby authorized and directed to prepare suitable regulations for the enforcement of the provisions of this act.

7. The Medical Department shall also perform such other duties as the President or the Secretary of War may deem for the best interest of the army.

All acts and portions of acts in conflict with the above are hereby repealed.

Should the ideas advanced in this paper meet with your approval, I most earnestly urge that you will take steps to have the public at large thoroughly informed on the subject. My object is and has been to obtain the best possible protection for the American soldier from preventable disease.

SATURDAY, OCTOBER 26, 1901.

DIAGNOSIS.

When called to a case, the young physician is apt to meditate more on what he shall prescribe rather than on what is the matter. As a student he was, perhaps, more diligently occupied in copying the pet prescriptions of his favorite teachers than in noting the care with which these same teachers sought to impress upon his mind the importance of diagnosis and the fact that a correct knowledge of the disease process, its cause and its natural course, must precede a rational therapy.

What the average practitioner thinks he wants, when, after a decade of practice, he attends a post-graduate school, is a knowledge of the new drugs and the latest method of treatment. He is satisfied with his ability to recognize typhoid fever, but has become discouraged because his last three cases died in spite of the treatment that had been so uniformly successful in scores of cases in years gone by. Had he made autopsies on his three cases perhaps he would have been surprised and shocked, and would have felt that his diagnostic, rather than his therapeutic, ability was at fault when he discovered no evidence whatever of typhoid, but an empyema in the one case, an ulcerative endocarditis in another, a tubercular meningitis in the third. Failure to make autopsies, lack of rigid criticism by consultants who are too prone to agree with the attending physician, and neglect of careful and repeated examinations in all cases that are atypical or in any way obscure, render a physician overconfident in his diagnosis; he often blames therapy where the fault is that he failed to understand rightly the nature of the disease.

The ability to make a correct diagnosis is not entirely the result of native genius. As Cicero said about the making of a poet, the natural ability is of great importance, but the man of surpassing merit is he who joins to his native talent the power that comes from education. The man of quick perception, of logical mind, and with acute special senses may make a rapid and apparently intuitive diagnosis. But in its ultimate analysis such a diagnosis is the result of study of books, and of experience at the bedside and in the laboratory; it implies weighing of probabilities and close logical reasoning; it is far from intuitive. This is the hard lesson to teach the young man who becomes discouraged as he ploddingly works over his case and still is unable to name the malady, or grows careless through his effort to work as rapidly as his preceptor or his superior. But practice in this line brings improvement as it does to the pianist, who soon reads and plays at sight music that was at first entirely beyond his grasp.

Many diagnoses are made with positiveness. When technique is faultless one may at times be able to pronounce a case tuberculous, or to declare the nature of a fragment of tumor, or the presence of fluid is proven by aspiration or a fracture recognized by crepitus, etc. Yet while the learned and trained physician is the most positive in his diagnosis when he is sure of his ground, no one is more cautious and guarded when positive signs are lacking, and no one more candid in saying, "I do not know." It takes some men many years before they attain that mental attitude commanding the wide horizon and giving them the clear vision so that they can look about and declare openly, "I do not know." Some men never reach this high plane; others lack the courage to confess what seems to be ignorance. But the intelligent layman who has tried his physician and not found him wanting, is willing to accept this confession of limitation of human power; he recognizes the feebleness of human insight into the workings of Nature, and he waits patiently until the physician is ready to announce his decision. The physician who is honest in his diagnosis has nothing to retract; he is not obliged to "hedge."

The physician who has had impressed upon him early the importance of diagnosis, who realizes the diagnostic ability is not a gift but an acquirement, and who gives his opinion not prematurely and guessingly, but conscientiously and after full deliberation, may not be brilliant, and may add little to the world's store of knowledge, but he goes about doing good; he commands the respect of his patients and his colleagues, and is free from the stings of conscience that come through mistakes committed through haste and carelessness.

THE DISTRIBUTION OF PHYSICIANS.

The recent census proves the source of not a few surprises in what concerns the distribution of physicians to the number of inhabitants in various parts of the country. It would not be surprising to find that doctors were most numerous in proportion to the population in the long-settled Eastern States. As a matter of fact this is not the case, however. California, Colorado, Kansas, Missouri, Iowa and Arkansas have more physicians to their population than any of the Eastern States except Vermont and Maryland. There are less inhabitants to each physician in Texas with its scattered population and magnificent distances than in Pennsylvania with its dense population, most of which is gathered into a few compact areas. Physicians are said to affect especially crowded centers of population, but some of these statistics would seem to contradict the old tradition and show that there is still a very large number of men who prefer a country life with its long, tiresome journeys to the pent-up city existence with its conveniences and social features, but absence of contact with nature.

With the exception of the District of Columbia, where, of course, many circumstances, such as political reasons, the glamour of fashion and of official life, and especially the presence of the medical headquarters of so many government departments, conspire to increase the number of physicians, California has more doctors to the population than any other part of the United States. The reputation of the State as a health resort is evidently responsible for this preponderance. Next after California in this matter comes Colorado, and for similar reasons. Physicians in delicate health are added to the practitioners who would naturally practice in the State, and, besides, graduates from a distance are attracted by the prospect of the superabundance of patients these States attract. For identical reasons Florida has distinctly a greater proportion of physicians to the population than any other Southern State.

It is evident from the census statistics that we must be rapidly approaching the limit of additions to the medical profession if the individual members are to find the practice of medicine a lucrative occupation. The New England States have an average of less than 600 inhabitants to each physician, New York has 596, while Pennsylvania provides 693 people for every doctor. New Jersey, with many health resorts but no medical school, and a rigorous examining board, has but one physician for every 881 inhabitants. The profession does not fare so well in the Middle Western States, where in Indiana there are but 519 people to each physician, in Ohio 529, in Michigan 575, and in Illinois 583. Meantime there are no special complaints of indigence among the members of the profession in California and the District of Columbia, though the number of inhabitants to each physician is respectively 392 and 389.

Curiously enough the distribution of the dentists of the country follows closely that of the physicians. They are thickest at the National capital, and after that in California. Colorado, for some reason not easy to understand, does not come third but is much lower in the list, the place being taken by Massachusetts. Utah has a very high place in the comparative number of dentists to the population, which would seem to show that the larger proportion of women in the State has led to the inevitable application of the rule of supply and demand. The prospects of making a living soon after graduation would seem to be still good in dentistry, the average number of dentists to the population of the country being only one to more than 4000 inhabitants.

HYPERTROPHY OF THE HEART.

Some new light has been thrown upon the manner in which the heart hypertrophies, and upon the causes that lead to cardiac hypertrophy both under physiological and pathological conditions, by the important work of Carl Hirsch.[1] Hirsch approached the problem in a somewhat different manner than previous observers; he employed more exact methods of study in that he separated the walls of the four cavities and considered each as an entity. This permitted the consideration of the relation of the mass of each cavity to that of the entire heart and of the general musculature of the body in health as well as in various diseases. It appears that the mass of the heart muscle is an expression solely of the work it accomplishes and that in sound individuals there is an intimate and direct relationship between the activity of the heart and the activity of the general musculature independent of conditions of general nutrition. Pregnancy was found to be of influence only in so far as it increased the activity of the muscles of the body as a whole. Glandular and nervous activity causes no direct effect upon the operations of the heart as expressed in its mass with the exception of exophthalmic goiter. Kaehl has demonstrated anatomically that the chief divisions of the heart are in reality quite independent of one another, and Hirsch shows that they are likewise independent functionally. Hypertrophy of one part may occur without any one of the other three parts participating. For example, in sclerosis of the thoracic aorta and splanchnic vessels the wall of the left ventricle is alone affected. On the other hand, in nephritis all sections of the heart are hypertrophied as a rule, a disproportional hypertrophy of the left ventricle being always due to vascular sclerosis according to Hirsch. In nephritis, however, the hypertrophy in incipient cases is limited more or less to the left ventricle, the other parts becoming hypertrophied as the disease progresses. Ewald suggests that in nephritis an increased viscosity of the blood is responsible for the hypertrophy of the heart, and since Hirsch's observations show that the obstruction to circulation must be of such character that the action of the whole heart is increased quite uniformly, Ewald's theory, although generally neglected, is considered by Hirsch to receive some support.

The opinion of Cohnheim that in weakness of the right heart the venous stasis may so increase the work required of the left heart that it may undergo hypertrophy, is widely accepted. But that this is the case Hirsch denies, citing in evidence cases in which there was protracted venous stasis without complicating valvular or arterial lesions and atrophy in place of hypertrophy of the left heart. This he explains by assuming that the accumulation of a large part of the blood in the vein lessens the amount of work that the left heart must do.

Another interesting observation is that in beer drinkers the hypertrophy known as "beer heart" indicates always an interstitial nephritis. Beer drinkers without nephritis have no hypertrophy of the heart.

In connection with these problems the study of the individual fibers in hypertrophied hearts by John Gutch[2] is of interest. He found that the increase in the size of the heart is to be explained by an increase in the size of the individual fibers, and that there is no evidence of new formation of muscle cells. The fibers increase chiefly in breadth, possibly also somewhat in length. He corroborates the statements of Hirsch in regard to hypertrophy of both sides of the heart in nephritis. The fibers in the left side are usually larger than those of the right, and the papillary muscles have smaller fibers than the walls whether the heart is normal or hypertrophied.

JOURNAL OF THE ASSOCIATION OF MILITARY SURGEONS.

The first number (August) of a new medical magazine, the *Journal of the Association of Military Surgeons,* has just come to hand. It forms a volume of 224 pages, much of which in this issue is taken up with the proceedings of the association, lists of members, etc., though there are also several original articles. During the present association year it will be issued quarterly, but it is the intention to ultimately adopt the monthly form, and to devote the space in future issues more fully to original contributed matter. The *Journal* occupies a hitherto unfilled niche in American medical journalism and it has our cordial wishes for its success. The list of the membership of the association it represents shows that it starts with what ought to be a very respectable assured patronage. It is under the able editorial management of Dr. James Evelyn Pilcher, Captain (retired), U. S. A.

THE PATHOLOGICAL INSTITUTE OF THE NEW YORK HOSPITALS.

The Pathological Institute of the New York State Hospitals is being reorganized under the auspices of the state commission in lunacy, which has appointed an advisory board of leading specialists in psychology, general biology, pathology, neurology, psychiatry, etc. The appointees represent the three university medical schools of the city of New York, namely, Cornell, Columbia and Bellevue, and also the asylums. The appointments are permanent, except those from the asylums, which are elective for a term of two years, thus permitting all the institutions to be represented in rotation on the board. It is the idea in the reorganization to utilize the institute for special instruction of the asylum staffs in psychiatry and research methods, as well as to encourage original work in the various sciences having a bearing on insanity. It is, therefore, to have its future location in connection with one of the divisions of the Manhattan State Hospital on Ward's Island until such time as a reception hospital for the insane can be provided. The advisory board includes Professor J. McKeen Cattell of Columbia University, Professor Ewing of Cornell University, Professor Herter of Bellevue, Dr. Henry Hun of Albany, Dr. Hermon C. Bumpus of the American Museum of Natural History to represent the department of general biology, Drs. Pilgrim and Macdonald representing the state hospitals, and Dr. Frederick Peterson ex-officio as president of the lunacy commission. With this advisory board and a competent working staff who will be selected, we shall look for first-class work from the institute. Its success will, we trust, incite other States to follow the example of New York, and it is to be hoped it will cause a marked advance in the appreciation of American psychiatry throughout the world.

A CAUTION TO MEDICAL WRITERS.

We had occasion to call attention editorially not long since to a method of reporting experimental work that seemed objectionable, as affording a chance for certain individuals to misconstrue facts and misrepresent and slander our profession. The special instance was then afforded by one of our English contemporaries; now we have a similar one among our domestic exchanges. A writer in the New York *Medical Record* of October 19, describing some disinfecting experiments, uses the following language: "Then followed a rest of several weeks, our victim going out of town. On his return, culture testing still proved that the staphylococcus pyogenes aureus was present, but guinea-pig inoculations showed it to be of lessened virulence." Here is material for the anonymous writer of the Humane Society, or that section of it that is proving the atrocities of human vivisection, to dilate upon. "Our victim" had, as the report shows, undergone finger scrapings and loss of pieces of skin; he had been scraped and skinned, as the humane individual could say, and this would afford all the text required for any amount of virtuous horror at such an instance of human torture. It would, of course, not be necessary for such purposes to quote the context, and any medical explanation of the facts could be ruled out as coming from those disqualified as being, in sympathy at least, participants in the outrage. Medical writers should be more careful and not expose themselves in this manner when the antivivisection wolf is about searching for such titbits to devour.

LEPROSY AND THE MOSQUITO.

The spread of leprosy in the Hawaiian Islands is attributed to some extent to the mosquito by the local health authorities. There are cases that occur that are otherwise unaccountable, a fact that will hardly increase the mental quietude of those who are mosquito bitten in a country where leprosy exists. Of course, this mode of infection must be extremely rare, for mosquito bites are common, and these unaccountable cases are few in number. It seems probable that the indictment against the mosquito will be, as time elapses, a much heavier one than has been as yet conceived; it is the most efficient little inoculating machine that was ever contrived, and it seems to have a constitution suited to take up and carry about a number of uncomfortable things for the human species. It is said that it did not exist in some at least of the Pacific Islands originally, but was introduced after their discovery by white men. Herman Melville, in one of his works that is not altogether fiction, attributes its introduction to the Society Islands to a whaler, who, out of spite against some natives, landed a cask of larva-breeding fresh water on one of the islands. If this is true it has turned out to be a veritable Pandora's box to the natives, with far greater possibilities of evil than he in his malice designed. At present malaria, leprosy, elephantiasis and probably other mosquito-borne diseases prevail locally or universally in the islands, and it would be an interesting study to trace up their medical history in all the different groups so as to determine how far the contact with civilization has been their causal factor.

INFECTION OF THE URINARY BLADDER FROM THE INTESTINE.

We have on a previous occasion[1] referred to observations made by Dr. R. Faltin with regard to infection of the urinary bladder in connection with disorders of the rectum. In order to determine whether such infection is a local process that takes place through the intermediation of the lymph stream or is merely part of a general process through the intermediation of the circulation Faltin[2] undertook a further experimental investigation, as a result of which he concludes that coprostasis induced by occlusion of the anus of from thirty-six to forty-eight hours' duration is not sufficient in general to cause an inundation of the body with intestinal bacteria. After artificial coprostasis of sufficiently long duration such changes in the intestine may take place that intestinal bacteria may gain entrance into the circulation either directly or through the intermediation of the peritoneum. Elimination of bacteria through the kidneys is possible under such conditions, but like the bacteremia itself it is to be looked upon as an antemortem process. Transitory bacteremia can not be produced. Following coprostasis of sufficiently long duration, intestinal bacteria may appear in the urinary bladder without first having entered the circulation. Under these circumstances such alterations in the organism have generally taken place that subsequently general infection, probably originating from the injured intestine or the bladder, often results. The bacteria in some cases gain entrance into the bladder by way of the urethra, in other cases probably by a direct route along the lymph paths, but whether through the lesions of the urethral mucous membrane or through injuries in the anal region has not yet been determined. Should retention of urine exist or have existed in consequence of ligature of the urethra, the presence of bacteria in the bladder is more frequent and cystitis may develop. It is pointed out that the foregoing conclusions are applicable only to experiments on rabbits, and it is not maintained that absorption of bacteria from the intestine and elimination of bacteria through the kidneys from any cause are in man always antemortem processes. While probably this is often the case, many clinical observations, as for instance in cases of typhoid fever, indicate clearly that bacteria may be absorbed from the intestine and eliminated through the kidneys without death necessarily following.

Medical News.

ALABAMA.

Smallpox.—The Health Officer of Jackson County reports 14 cases of smallpox among negroes at Hollywood.

The Medical College of Alabama, Mobile, opened October 12 with an address by the dean, Dr. George A. Ketchum.

Health of Montgomery.—The report of the Sanitary Department of Montgomery for the fiscal year shows a marked decrease in the cases of diphtheria and smallpox, and an increase in scarlet fever, as compared with the previous year. The total number of scarlet fever cases was 151, all of mild type. During the current year 6 cases of diphtheria and 13 cases of smallpox were reported, the respective figures for the previous year having been 14 and 268.

ARIZONA.

Personal.—Dr. Oscar Brandon, Nogales, has located at Naco.——Dr. F. L. A. Hamilton has moved to Nogales from Wagoner, Ind. Ter.

"Manila Itch" is said to be almost uncontrollable in the Gila Valley, at Solomonsville, Safford and other Mormon settlements. The disease was at first diagnosed as smallpox, and under rigid restriction and quarantine, soon disappeared. When, however, a "health officer" discovered that the disease was not smallpox, the restrictions were relaxed with the usual results.

Restriction of Tuberculosis.—The governor of Arizona intends to recommend the creation, under legislative authority, of a Territorial Board of Health, investing its officers with full power to quarantine and segregate persons coming into the territory afflicted with consumption, precisely along the lines of the power of the boards of health of the various states in quarantining against any dangerous contagious disease, and that a law be passed prohibiting consumptives from living in hotels and boarding-houses with well people, and requiring them to live upon the desert in such places or sanitariums to be provided, and in such localities where the possibility of contagion will be as greatly reduced as circumstances permit.

Campaign Against Tuberculosis.—The city council of Phoenix has passed ordinances to protect the public from tuberculous patients and prevent the spread of tuberculosis. The first of these provides for the placing of cuspidors or proper receptacles at street crossings and at parks, under the direction of the health officer, which shall contain disinfectants, and the second order that each room in a hotel, lodging-house or private residence, left vacant by a sufferer of consumption, shall be properly disinfected. A charge will be levied against the proprietor, or those who receive invalids, for each consumptive accepted, the sum to be applied to the fumigation of the room when the occupant leaves.

CALIFORNIA.

Smallpox and typhoid fever are reported from Walnut Grove, Sacramento County.

Dr. Thomas Howlett, formerly interne at St. Mary's Hospital, San Francisco, has been appointed resident physician at Dr. Clark's hospital, Gilroy.

University of California Medical School.—The Board of Regents of the State University has decided to take over the entire management of the medical school which heretofore has been only one among several medical and so-called medical colleges of the state.

COLORADO.

Dr. David I. Christopher, Colorado Springs, has been appointed house physician for the National Printers' Home at that place.

A physicians' business league has been organized at Victor, comprising membership from all over the district. It is for the purpose of social and intellectual intercourse and for the special advantage of the medical fraternity in protecting themselves against bad debtors.

Denver Diphtheria Deaths.—In the six years from 1889 to 1894, inclusive, before antitoxin was employed, 2272 cases of diphtheria occurred in Denver, with 827 deaths, a mortality of 36.4 per cent.; during the following six years since antitoxin has been in use, 1641 cases occurred, with 175 deaths, a mortality of 10.66 per cent.

Diphtheria, Scarlet Fever and Smallpox.—During September there were reported to the State Board of Health, 105 cases of diphtheria, 102 of scarlet fever and 15 of smallpox. Compared with August, these figures show an increase of 34 cases of diphtheria, and a decrease of one case of scarlet fever and 37 cases of smallpox.

Crusade Against Unlicensed Practitioners.—The State Board of Medical Examiners has obtained warrants for the arrest of Drs. Albert L. Bennett and J. Sterling Johnson, regulars; John T. Bass, Elizabeth C. Bass and H. Van King, osteopaths, and J. Howard Hiltz, magnetic healer, on the charge of practicing without having presented to the State Board of the individual fibers, and that there is no evidence of new formation of muscle cells. The fibers increase chiefly in breadth, possibly also somewhat in length. He corroborates the statements of Hirsch in regard to hypertrophy of both sides of the heart in nephritis. The fibers in the left side are usually larger than those of the right, and the papillary muscles have smaller fibers than the walls whether the heart is normal or hypertrophied.

When, however, a "health officer" discovered that the disease was not smallpox, the restrictions were relaxed with the usual results.

Restriction of Tuberculosis.—The governor of Arizona intends to recommend the creation, under legislative authority, of a Territorial Board of Health, investing its officers with full power to quarantine and segregate persons coming into the territory afflicted with consumption, precisely along the lines of the power of the boards of health of the various states in quarantining against any dangerous contagious disease, and that a law be passed prohibiting consumptives from living in hotels and boarding-houses with well people, and requiring them to live upon the desert in such places or sanitariums to be provided, and in such localities where the possibility of contagion will be as greatly reduced as circumstances permit.

Campaign Against Tuberculosis.—The city council of Phoenix has passed ordinances to protect the public from tuberculous patients and prevent the spread of tuberculosis. The first of these provides for the placing of cuspidors or proper receptacles at street crossings and at parks, under the direction of the health officer, which shall contain disinfectants, and the second order that each room in a hotel, lodging-house or private residence, left vacant by a sufferer of consumption, shall be properly disinfected. A charge will be levied against the proprietor, or those who receive invalids, for each consumptive accepted, the sum to be applied to the fumigation of the room when the occupant leaves.

CALIFORNIA.

Smallpox and typhoid fever are reported from Walnut Grove, Sacramento County.

Dr. Thomas Howlett, formerly interne at St. Mary's Hospital, San Francisco, has been appointed resident physician at Dr. Clark's hospital, Gilroy.

University of California Medical School.—The Board of Regents of the State University has decided to take over the entire management of the medical school which heretofore has been only one among several medical and so-called medical colleges of the state.

COLORADO.

Dr. David I. Christopher, Colorado Springs, has been appointed house physician for the National Printers' Home at that place.

A physicians' business league has been organized at Victor, comprising membership from all over the district. It is for the purpose of social and intellectual intercourse and for the special advantage of the medical fraternity in protecting themselves against bad debtors.

Denver Diphtheria Deaths.—In the six years from 1889 to 1894, inclusive, before antitoxin was employed, 2272 cases of diphtheria occurred in Denver, with 827 deaths, a mortality of 36.4 per cent.; during the following six years since antitoxin has been in use, 1041 cases occurred, with 175 deaths, a mortality of 10.66 per cent.

Diphtheria, Scarlet Fever and Smallpox.—During September there were reported to the State Board of Health, 105 cases of diphtheria, 102 of scarlet fever and 15 of smallpox. Compared with August, these figures show an increase of 34 cases of diphtheria, and a decrease of one case of scarlet fever and 37 cases of smallpox.

Crusade Against Unlicensed Practitioners.—The State Board of Medical Examiners has obtained warrants for the arrest of Drs. Albert L. Bennett and J. Sterling Johnson, regulars; John T. Bass, Elizabeth C. Bass and H. Van King, osteopaths, and J. Howard Hiltz, magnetic healer, on the charge of practicing without having presented to the State Board of

---

[2] Centralblatt für die Krankheiten der Harn- und Sexualorgane, B. xii, H. 9, p. 465.

Medical Examiners any diploma as a graduate of medicine; without having furnished any other evidence of graduation from a medical school; without having complied with the medical practice acts of 1881 and 1885.

CONNECTICUT.

Hospital Site Vetoed.—The mayor of New Haven has returned without his approval the order establishing a hospital for contagious diseases at Springside on account of its distance from the city.

In Memoriam.—At the semi-annual meeting of the Hartford County Medical Society, held October 16, obituaries on the following deceased members were pronounced: On Dr. George C. Jarvis, Hartford, by Dr. Horace S. Fuller, and on Dr. Sidney R. Burnap, Windsor Locks, by Dr. Joseph A. Coogan.

Dr. Patrick J. Callaghan, Waterbury, arrested on the complaint of the county health officer, on the charge of practicing medicine without a license, and fined $100 and costs, has appealed, and intends to test the validity of the state law. Dr. Callaghan's offense is that he had not registered with the county health officer as required by the medical practice act.

Personal.—Dr. Henry S. Noble has been elected superintendent of the Connecticut Hospital for the Insane, Middletown, vice Dr. Charles W. Page, resigned.——Dr. John E. Martin has succeeded Dr. Lawrence M. Cremin as attending physician at the New Britain General Hospital.——Dr. P. Frederick Metz, New Haven, charged with malpractice, will not appear for trial; he has forfeited his bond and left New Haven.

DISTRICT OF COLUMBIA.

District Diseases.—Diphtheria is on the increase in the District; 60 cases are in isolation in 33 houses. Of scarlet fever there are 23 cases, and of smallpox 9 cases.

Personal.—Drs. John W. Mitchell and William H. Hughes, both of Washington, have been appointed assistant surgeons in the Freedmen's Hospital.——Dr. Benjamin B. Wechsler, Washington, has located in Knoxville, Tenn.——Dr. A. L. Swain, Washington, has moved to Athol, Mass.

Ask Adequate Remuneration.—The Board of Medical Supervisors of the District in its annual report calls the attention of the Commissioners to the fact that no provision is made for the adequate compensation of the various boards of medical examiners, or of the Board of Medical Supervisors. The members of these boards perform their duties solely in the interest of the public, and, under existing law, receive for their services whatever happens to be left over from the fees paid by applicants for licenses after the necessary expenses of the board have been deducted. No member of the board of eclectic medical examiners has received a cent for his services. The average amount received per annum by each member of the board of homeopathic medical examiners has been $1.75; by the lay members of the Board of Medical Supervisors, $20, and by the members of the Board of Medical Examiners, $32.14. The total number of applications is 1559, and the total number of licenses issued is 1411. It therefore requests that provision be made to pay each member of the Board of Medical Supervisors and each member of the Board of Examiners $10 for each meeting attended.

ILLINOIS.

Smallpox.—Springfield now has 31 cases of smallpox, and cases have also been reported from Riverton and Rochester.

The De Witt County Medical Society has passed a resolution that no physician shall be eligible to membership unless he has practiced medicine in the county one year.

Physicians' Club Reception.—Drs. John H. Mannon and Charles W. Hall, who have recently returned from Europe, were given a reception by the Physicians' Club of Kewanee, October 11.

Hospital Addition Postponed.—Although more than $6000 has been subscribed for the addition to the Rockford City Hospital, it has been determined to postpone building until next spring and to devote the winter to the completion of the fund necessary for the erection of the building.

Personal.—Dr. Lewis A. McFadden, Peoria, a member of the board of aldermen, has been appointed Health Commissioner, vice Dr. William T. Sloan, resigned.——Dr. Robert E. Calhoun, Chesterville, is taking post-graduate work in Chicago.——Dr. Arvid E. Kohler, Moline, is seriously ill at the Baptist Hospital, Chicago.

Moline Hospital Troubles.—The Moline Public Hospital staff has unanimously adopted resolutions asking the mayor to remove the present board at once, and in its place appoint a board of three physicians. Also to appoint an advisory board, to consist of physicians who shall be made regular members of the board as soon as the law can be changed by the legislature, making the board legally consist of seven members, instead of three, as at present.

St. Francis' Hospital Staff.—The medical staff at St. Francis' Hospital, Peoria, consists of Dr. Rufus A. DuMars, president; Dr. Ernest B. Studer, secretary, and Drs. Charles E. Davis, Alvin N. Keith, Frank C. Bourscheidt, Clifford N. Collins, Lewis A. McFadden, William H. Willis, Roland L. Green, Joseph V. Studer and Joseph J. L. Finnell. Dr. Edwin H. Bradley is the oculist, and Drs. Joseph Studer and Leonard H. Spalding comprise the consulting staff.

Chicago.

Medical Examiners Dine.—The medical examiners of the New York Life Insurance Company held a conference and dined together, October 19. Dr. Harry P. Woley presided, and among the topics discussed were family history, venereal disease, albuminuria and appendicitis.

To Avert Smallpox.—With a view to prevent the importation of smallpox, Chief Medical Inspector Dr. Heman Spalding, of the Department of Health, is visiting neighboring towns and aiding the local authorities to check the disease. He has recently visited Harvey and New Holland, Ill., and Michigan City, Ind.

"Passing-up" Prohibited.—President Harper welcomed 275 Rush medical students, both freshmen and sophomores, into the University of Chicago at Kent Theater, October 15, and then officially informed them that hereafter "passing-up" students and other ungentlemanly conduct in the lecture-rooms would not be tolerated.

University of Chicago Medical Club.—The first meeting of this Club, a medical society organized by the University of Chicago, was held at the Hull Physiological Laboratory, October 21. A paper was read by Dr. Jacques Loeb, on "The Influence of the Valency and Possibly the Electrical Charge of Ions Upon Their Antitoxic Effects," and one by Dr. Albert Peacock on "A Case of Myiosis in Man."

St. Gerard's Hospital, established a year ago, is insolvent, and a receiver has been appointed. The liabilities are said to be $8300 with assets of $2400. The plan of the projectors of the hospital was to care for as many charity patients as the patients who pay could support. For several months the charity patients exceeded in numbers those who could afford to pay and the hospital's affairs grew worse constantly. The income was far insufficient and contributions practically stopped.

The Lowest Death Rate.—A total of only 370 deaths from all causes recorded last week establishes the lowest weekly death rate in the annals of the Health Department. The mortality is at the annual rate of 10.95 per thousand. The lowest rates during the previous five years were 11.04 for the week ended Nov. 10, 1900; 11.28, week ended Oct. 29, 1898; 11.72, week ended Nov. 27, 1897; 12.12, week ended Nov. 25, 1899; and 12.20, week ended Nov. 7, 1896—an average of 11.67, or 6.5 per cent. higher than last week's rate. This marvelously low figure is due chiefly to the decrease of deaths from apoplexy, bronchitis, cancer, consumption, convulsions, heart disease, nervous diseases and pneumonia—there being 31 fewer deaths from consumption alone and a total of 71 fewer from the diseases specified than during the previous week.

INDIANA.

Hammond Hospital and Training School has been incorporated at Hammond by Dr. John C. Pannenborg and others, with a capital stock of $10,000.

Diphtheria is so prevalent at New Albany that the Board of Health has ordered the schools to be closed, and all public meetings to be interdicted. The disease has reappeared at Knox.

T[illegible] Fever.—There are 16 cases of typhoid fever at th [illegible] y, Jeffersonville, due in the opinion of the secretary of the State Board of Health to infected water supply.

Smallpox.—The situation at Mooerstown is improving rapidly.——Six cases have been reported from School District Number 1, Wabash Township, Adams County, and the public school in that district has been closed.

Medical License Cases.—Drs. W. F. Reinhardt and E. N. Flint, Indianapolis, have appealed from the decision of the

State Board, refusing them licenses.——Dr. George McD. Ober, Indianapolis, was arrested at Madison, October 11, for practicing without a license.——The Appellate court has modified its mandate in the action to revoke the physician's license held by Dr. Jacob B. Oliver, Brazil, so as to direct that a new trial be granted and further proceedings be had not inconsistent with the recent decision of that court reversing a judgment in Dr. Oliver's favor.

Expelled.—At a meeting of the Knox County Medical Society at Vincennes, October 14, Dr. Thomas H. Maxedon was expelled from the Society on the allegation of unprofessional conduct. The charges on which this action is based are that Dr. Maxedon sought notoriety in the newspapers; that he instituted suit against his fellow-practitioners, and that he recently gave improper testimony in a trial. Immediately after the expulsion, Dr. Joseph F. Somes resigned as a member of the Society. Dr. Maxedon claims that the action is summary, and that the charges are due to professional jealousy, and says that he will appeal for redress to the State Board.

Mortality in Indiana.—The reports to the State Board of Health for September show 2825 deaths, a rate of 13.6 per 1000 per annum. This is a decrease of 107 as compared with the preceding month and a decrease of 296 as compared with the corresponding month of 1900. All the cities in the State, with a population of 847,302, report 1052 deaths, which is a rate of 15.1 per 100,000. This exceeds the rate for the whole state by 1.5, and compared with the preceding months is a decrease in the rate of .4. The number of deaths classified according to important ages in the cities, was, under 1 year of age 221, 1 to 5, inclusive, 89, 65 and over 219. The country deaths numbered 1773, a rate of 12.9 per 100,000, which is 2.2 less than the city rate. The death rate from pulmonary tuberculosis in the country was 121.3, and for the cities 141.1 per 100,000. The typhoid rate for the country was 98.6, cities 76.3. The diphtheria rates, rural and urban, were 12.4 and 27.3 respectively. The diarrheal rates were, rural, 177.6; urban, 162.7; puerperal fever shows a rural rate of 2.9 and an urban rate of 4.3. This reverses the usual order. The cancer rate was, rural 46.7, urban, 59. Only in typhoid fever and diarrheal diseases does the rural rate exceed the urban. Tuberculosis caused the greatest number of deaths, 296; of these 264 were from pulmonary tuberculosis. The deaths from typhoid fever numbered 188; diarrheal diseases, 356; diphtheria, 36; scarlet fever, 4; whooping cough, 16; pneumonia, 73; cerebrospinal meningitis, 17; influenza, 4; puerperal fever, 7; cancer, 105, and violence, 113.

MARYLAND.

State Examination.—The State Board of Medical Examiners will hold the semi-annual examinations for license to practice medicine at the Medical Hall, Baltimore, November 6 to 9. The subjects are anatomy, physiology, surgery, hygiene, practice, pathology, chemistry, medical jurisprudence, materia medica, therapeutics, obstetrics and gynecology. A fee of $10 must accompany each application.

Baltimore.

Dr. Edmund G. Waters, while visiting a patient, October 18, fell down a stairway and fractured his left leg.

The mortality for the week ending October 19, was 177, or 17.77 per 1000 per annum. The white rate was exactly one-half of the black.

Yale's Bicentenary.—On October 22, at the bicentennial celebration of Yale University, Professor Wm. H. Welch, of this city, delivered an address on "Yale in Its Relation to Medicine," and Dr. Daniel C. Gilman, one on "Yale in Its Relation to Science and Letters."

Personal.—Dr. Jose L. Hirsh has returned from his wedding trip.——Dr. Charles E. Simon has returned from summering in Nova Scotia.——Dr. Jessie E. Sweet, who has completed a course at the Presbyterian Eye, Ear and Throat Charity Hospital, has returned to her home, Pine Bluff, Ark.

Detention Hospital.—Mr. Jeffrey R. Brackitt, president of the Board of Charities and Corrections, recommends the establishment of a temporary place of detention for emergency insane cases in the central part of the city. Attention was called to such a provision by the death of an insane patient shortly after being committed to jail last July.

St. Joseph's Hospital Annex.—The $30,000 annex to St. Joseph's Hospital will be opened November 5. The fund for its erection was raised by the Ladies' Auxiliary. It will accommodate about 75 patients, bringing the total capacity of the institution to 275. A steam laundry and a crematory for the burning of bandages, dressings, etc., have been installed. The addition will contain two negro wards and ten private rooms. It is in the rear of the main building.

Tablet to Professor Martin.—A large and beautifully framed bronze tablet to the memory of the late Professor Henry Newell Martin has been erected in the corridor of the biological laboratory at Johns Hopkins University. It bears this inscription: "In Commemoration of Henry Newell Martin of Neury, Ireland, A Graduate of the Universities of Cambridge and London, Fellow of the Royal Society, the First Professor of Biology and of Physiology in This University. By his brilliant work as investigator, teacher and author, he advanced knowledge and exerted a wide and enduring influence. Appointed in 1876. Resigned in 1893. Born in 1848. Died in 1898." A memorial meeting to the late Professor Henry A. Rowland, of the same institution, will be held in the physical laboratory, October 26, when Dr. T. C. Mendenhall, former president of the Worcester Polytechnic Institute, will make the address.

MASSACHUSETTS.

School Inspection in Worcester.—Dr. John T. Duggan, Worcester, chairman of the committee appointed to consider the matter of medical inspection in the public schools of that city, has asked for an appropriation of $3000 for that purpose.

West Roxbury Hospital.—Through the liberality of Abby L. A. Faulkner, Jamaica Plain, a hospital is to be erected and devoted to the care of the sick in the section of Boston known as the old town of West Roxbury. The buildings are to cost about $100,000.

Tuft's College Medical School.—The formal opening of the new medical and dental building of Tuft's College, Boston, took place October 3. President Elmer T. Capen, presided; Dr. Frederick W. Hamilton, chairman of the executive committee of the trustees, presented the building to the medical and dental faculties, and Dr. Harold Williams, dean of the schools, made the address of acceptance.

Personal.—Dr. Francis E. Corey, Westboro, has moved to Redlands, Cal.——Dr. Frank A. Foster, Waltham, has disposed of his practice and moved to Newton.——Dr. Leslie H. Hendee, Palmer, has moved to Westfield.——Dr. Homer Connor has opened an office in Haverhill.——Dr. Francis Shaw, Worcester, has located in Somerville.——Dr. and Mrs. Charles Hale Cogswell, Boston, intend to spend the winter in travel.

MICHIGAN.

Virchow.—The Detroit Medical Society has sent a congratulatory cablegram to Dr. Rudolph Virchow.

Smallpox Fees.—The Calhoun County Medical Society has fixed the fee for attending smallpox cases at $10 a visit.

Personal.—Dr. J. W. Toan, Otsego, has moved to Grand Rapids.——Dr. T. Bennett Scott, Vernon, has sold his practice to Dr. Louis Fleckenstein, Port Hope, who is now taking a post-graduate course in Chicago.

Card Catalogue of Graduates.—The secretary of the medical faculty of the University of Michigan, Dr. G. Carl Huber, has prepared a complete card catalogue of the alumni and alumnæ of the medical department.

Hospital Site Accepted.—The Hospital and Home Association of Port Huron has accepted Charles Baer's offer of a hospital site of three lots, and $1000 in cash toward the erection of a new hospital building. It will be necessary to raise $20,000 by popular subscription.

MINNESOTA.

Diphtheria is reported in St. Paul and Sletten.

Licensed to Practice.—The State Board of Medical Examiners, on October 11, issued licenses to practice to 19 candidates.

Swedish Hospital.—The cornerstone of the new Swedish Hospital, Minneapolis, was laid with appropriate ceremonies, October 6. The building is to be three stories high and will cost about $40,000.

Compulsory Vaccination.—Until the Supreme court decides otherwise, not a child will be admitted to the public schools of St. Paul until it has been furnished the required certificate of vaccination. This dictum of Dr. Justus Ohage is being combatted by the local anti-vaccination society. In St. Paul fully 2000 children are not attending school on account of failure to comply with the requirements of the Health Department.

Smallpox.—Smallpox exists at Slayton, Murray County, and at Gary, Norman County.—There have been many deaths among the Indians in Mille Lacs County.——The disease is reported among the scattering bands of non-reservation Indians who roam about the vicinity of Sandy Lake, north of Aitken and McGregor.—Six cases were reported in Minneapolis in a Polish settlement in one day.——Several cases have been reported at Pelican Rapids and the public schools at that place have been closed.

Owatonna Hospital.—The Owatonna Hospital Board has passed a resolution that each patient shall be furnished by his attending physician with a certificate of his condition, on a form to be furnished by the hospital board, which certificate shall be given to the superintendent upon admission to the said hospital; and that the said certificate shall show that at the time of admission the patient is not suffering from smallpox, diphtheria, measles, scarlet fever, or pulmonary tuberculosis, all which cases are barred from admission to the hospital.

Personal.—Dr. Joseph G. Skaro, Minneapolis, is critically ill with nervous exhaustion in a hospital in that city.——Dr. John R. Petersen, Madison, is taking a post-graduate course in Philadelphia.—Dr. George G. Eitel, Minneapolis, is studying in Berlin.——Dr. James B. White, Montgomery, is about to locate in Faribault.——Dr. Ernest Z. Wanous, Rochester, has returned from a month's trip to the Atlantic seaboard.——Dr. Devereaux, Minneapolis, has located in St. Cloud.——Dr. H. C. Stuhr, Crookston, has opened an office in McIntosh.——Dr. Frank C. Davis, Minneapolis, is taking post-graduate work in Berlin.

MISSOURI.

Epidemic Disease.—Smallpox is reported at Cawood and Kansas City; scarlet fever at Hartville, Springfield, Ozark and Billings, and diphtheria in Springfield.

Marion-Sims-Beaumont Laboratory.—The new laboratory of the Marion-Sims-Beaumont Medical College, St. Louis, is now ready for occupancy. Dr. Meade Bolton, of Johns Hopkins University, has been elected director of the laboratory.

Personal.—Dr. Charles B. Lawrence, Stet, has moved to Woolstock, Iowa.——Dr. John Powers, Urich, has located in Clinton.——Dr. Thomas J. Halsey, Triplett, Chariton County, has moved to Drexel.——Dr. R. S. Bennett, Drexel, will spend the winter in study in New York.

Dr. James A. Manahan, Kansas City, assistant city physician, who was summarily discharged by the mayor, a few days ago, claims that the mayor has no authority in the matter, and that only the city physician, Dr. George O. Coffin, has the right to discharge him. He accordingly reports for duty as usual.

Virchow Banquet.—On October 13, one hundred and ten physicians and scientists met at St. Louis, at a banquet held in honor of the eightieth birthday anniversary of Rudolph Virchow. Dr. Robert Luedeking presided. Addresses were delivered by Dr. Hugo Summa on "Rudolph Virchow"; by Dr. Willard Bartlett on "Virchow the Pathologist"; by Dr. Amand N. Ravold on "What Hygiene Owes to Virchow"; by Dr. Robert Terry on "Virchow's Work in Anthropology"; by Mr. Charles Nagel on "Virchow as a Public Man," and by Mr. Perry Post Taylor on "Medicine as a Cosmopolitan Science."

NEW JERSEY.

Diphtheria is prevalent in Bloomfield, where 18 cases have been reported, and Brookside school has been closed for fumigation.

The Lost Hospital.—Crawford had an isolation hospital last spring. It was a substantial wooden building, 22 by 22 by 10 feet. A few days ago the chairman of the Board of Health went to inspect the hospital and could find no trace of it.

Panic in Hospital.—Fire caused a panic in the Paterson General Hospital, October 8, which might have been attended with serious results but for the coolness displayed by the superintendent and nurses. The patients were promptly removed and the fire extinguished.

Hospital Changes.—Dr. Norman L. Rowe, whose term as house surgeon at Christ Hospital, Jersey City, expires November 18, will be succeeded by Dr. Souloff. Dr. Darling has been appointed ambulance surgeon.——Dr. W. J. Hickson, resident physician of the Atlantic City Hospital, has resigned.

Dr. D. Warren Poor, East Orange, has been appointed medical inspector of the Orange public schools. His duties consist in responding to the call of the superintendent, examining suspects, and if he finds them afflicted with an infectious or a contagious disease to send them home with instructions to consult a physician. It will not be his duty to treat the cases. For more than a year Dr. Edgar C. Seibert, president of the board, has been urging the necessity of inspection, and Dr. M. Herbert Simmons one of the commissioners, and Superintendent William M. Swingle have ably seconded his endeavors.

Endorsement of McKinley's Physicians.—Dr. Charles F. Lehlbach, Newark, secretary of the Practitioners' Club of that city, has transmitted the following preamble and resolutions: "The Practitioners' Club of Newark, N. J., at its regular session, October 7, 1901, desires to express its highest appreciation of the courage, skill and professional ability displayed by the physicians in attendance upon the late President William McKinley: Be it therefore resolved, that the club regrets exceedingly that so unjust, uncalled for, unfair and arrogant a criticism should be made as appeared in the *New York Medical Record* of September 21, and hereby expresses its indignation and disapprobation. The club resolves furthermore, that a copy of this resolution be forwarded to the publishers of the *Medical Record, American Medicine,* and The Journal of the American Medical Association.

NEW YORK.

Personal.—Dr. Myron W. Hunt, Holland Patent, has located in Canastota.——Dr. Charles B. Sprague, Pottersville, will take a course of post-graduate study in New York City.

Elmira Isolation Hospital.—The health authorities of Elmira are having difficulty in obtaining a site for their isolation hospital. There is urgent need for such an institution, as a few cases of smallpox still exist in the city.

To Enforce the Ordinance.—A crusade against delinquent physicians who fail to make official reports of the cases of pulmonary tuberculosis which they are called to attend has been decided on by the health bureau and law department officials of Rochester.

New Rochelle Hospital Troubles.—The medical staff of the hospital at New Rochelle has resigned because the board of governors has passed a resolution making their terms only one year. The ten leading physicians of that city formed the medical staff. They say it was agreed that once a physician was appointed to the staff he should enjoy a perpetual tenure of office.

New York City.

New Harlem Hospital.—The Board of Estimate has authorized a bond issue of $275,000 for the construction of a hospital in Lenox Avenue between 136th and 137th streets, to be known as the New Harlem Hospital.

Merchant Marine Hospital Service.—Dr. William T. Jenkins, who has been in Europe for six weeks, is organizing a Merchant Marine Hospital Service to afford medical service to foreign merchant seamen in New York and other ports.

New Woman's Hospital.—The new hospital which the trustees of the New York Medical College and Hospital for Women are erecting as an addition to the present building will probably not be completed before the first of next year. The building will cost $45,000, and all but $6,000 of this had been secured before the new hospital was begun. At present over $3,000 more has been collected. The new addition will contain eighty rooms, besides a large operating theater and other necessary offices.

New York School of Clinical Medicine.—A course of clinical lectures with demonstrations will be given at the New York School of Clinical Medicine, 328 West 42d St., on Tuesday evening, commencing October 22. Members of the medical profession are cordially invited. The following subjects will be considered in the autumn course: October 22,—"Various types of chronic endometritis and their treatment," by Dr. Augustin H. Goelet; October 29,—"Scalp wounds and cranial fractures," by Dr. Thomas H. Manley; November 5,—"Some new studies on delirium tremens and alcoholic toxemia, illustrated," by Dr. Thomas D. Crothers; November 12,—"The operative treatment of traumatic and pathological lesions of the joints," by Dr. Robert H. Cowan; November 19,—"Diseases of the naso-pharynx and their treatment," by Dr. Max J. Schwerd; November 26,—"Diseases of the testes and their investments," by Dr. Carl E. Pfister; December 3,—"How to measure, fit and adjust the corset for movable kidney," by Dr. A. E. Gallant; December 10,—"Treatment of chronic gastric catarrh," by Dr. Heinrich Stern, and December 17,—"Trachoma —granulated lids—and its treatment," by Dr. J. Albert Meek.

OHIO.

Cornerstone Laid.—The cornerstone of the addition to St. Elizabeth's Hospital, Dayton, was laid with appropriate ceremonies, October 4.

Isolation Hospital.—The new smallpox hospital at Cleveland, two stories high and with four wards accommodating 80 patients and 8 private rooms, is ready.

Hospital Ward Donated.—Miss Sadie Tod, Youngstown, has notified the trustees of the City Hospital, Warren, that she will donate and equip a ward in the new hospital.

Fountain Park Sanatorium.—Drs. George W. Pickering and Robert Henderson, Urbana, have taken charge of the large hotel building at Fountain Park and will convert it into a sanatorium.

Dr. George W. Crile, Cleveland, has been awarded the Alvarenga Prize for 1901, for his essay entitled "An Experimental and Clinical Research into Certain Problems Relating to Surgical Operations."

Dr. Albert P. Ohlmacher, who recently left Gallipolis for Chicago, has been appointed non-resident director of the pathological laboratory of the Ohio Hospital for Epileptics, Gallipolis, and Dr. Theodore L. Chadbourne, at present assistant physician, was promoted to the position of resident pathologist.

Cleveland City Bacteriologist.—Dr. George C. Ashmun, Cleveland, has introduced an ordinance in the city council providing for the appointment of a city bacteriologist at a salary of $1500 per year, who shall work in conjunction with the health office, and who shall furnish trustworthy information respecting the purity and impurity of air, water, and all food substances, and for the prompt detection and prevention of dangerous infectious diseases.

Communicable Diseases.—Diphtheria is reported at Findlay, Cambridge and Zanesville.——Dresden, McConnelsville, Marietta and Cumberland have quarantined against Zanesville on account of the disease.——Smallpox has appeared at Newark, Zanesville and Chatham, and 12 cases are reported at Clay Lick.——Scarlet fever is increasing in Columbus, and the schools of Amanda have been closed on account of the prevalence of the disease at that place.

Personal.—Dr. Peyton E. Cromer, Piqua, has moved to Emporia, Kan.——Dr. Harry B. Kurtz, Leetonia, has located in Elkhart, Ind.——Dr. Yost, Lorain, has decided to locate in St. Paul, Minn.——Dr. Starling S. Wilcox, acting assistant surgeon, U. S. Army, has resigned and resumed practice in Columbus.——Dr. and Mrs. Thomas M. Sabin, Warren, have returned from a trip to Las Vegas, N. M.——Dr. P. R. Bennett, Urbana, has moved to Daytona, Fla.——Dr. William M. Lottridge, Portsmouth, intends to move to Newport, Ky.——Dr. S. D. Good, Newton Falls, has disposed of his practice and will take post-graduate work in New York and Chicago.——Dr. John R. Pipes, Cleveland, has located in Urbana.——Dr. George N. Simpson, Warren, has opened an office in Youngstown.

Fire at Gallipolis Hospital.—During the night of October 15, the pathological laboratory of the Ohio Hospital for Epileptics, Gallipolis, was totally destroyed by fire of unknown origin. Along with the destruction of a splendid equipment for pathologic research a more deplorable loss was sustained in the material which had been accumulated for four years by Dr. A. P. Ohlmacher, director of the laboratory, a material obtained from 176 thorough postmortem examinations of epileptics and including this number of epileptic brains, representing most if not all the phases of the morbid anatomy of the disease. These brains were all properly preserved and in good condition for future study, and numbered among them a remarkable series representing various types of epileptic idiocy and infantile cerebral paralysis. It is no exaggeration to say that this was the most complete and valuable collection of its kind in America. Dr. Ohlmacher's private collection of specimens of embryology, pathology and comparative anatomy was also destroyed.

Cincinnati.

The Laura Memorial Woman's Medical College has opened with a large initial enrolment of students.

St. Mary's Hospital.—At the October meeting of the staff of St. Mary's Hospital, Dr. Thomas Hays was elected to fill the vacancy occasioned by the death of Dr. T. P. White; Dr. H. Freudenberger was elected to the position of pathologist.

Higher Requirements.—The new state medical law requiring students of medicine to have an academic education before matriculating at the local colleges is causing a falling off in the sale of tickets for the clinics at the City Hospital. Heretofore about 250 tickets were sold annually, but this year only 166 have been taken out to date.

Personal.—Dr. Henry W. Bettman has been elected trustee to the Cincinnati Public Library in place of the late Dr. T. P. White.——Dr. Byron Stanton has been elected president of the State Board of Health, vice Dr. W. T. Gemmill, Forest, retired.——Dr. Daniel S. Young, one of the oldest and most esteemed local practitioners, is critically ill with pneumonia at the City Hospital.

PENNSYLVANIA.

West Penn Medical College, Pittsburg, opened for the year, October 2, with an unusually large attendance.

York Hospital.—The trustees of York Hospital are endeavoring to secure for the institution $4500 provided for in the act of assembly of 1874.

Reading Hospital Election.—On October 12, the managers of the Reading Hospital elected William B. Smith, president; Charles Rick, vice-president; Dr. Israel Cleaver, secretary, and P. R. Stetson, treasurer.

Epidemic Disease.—Diphtheria at Forestville has 12 cases.——Verona reports a dozen cases of typhoid and a large number of cases of diphtheria.——The schools of East Berlin, closed on account of diphtheria, have reopened.——Johnstown has 44 cases of scarlet fever, with 6 deaths.

Personal.—Dr. Benjamin H. Detwiler, Williamsport, was given a banquet by the profession of Williamsport and its vicinity, October 7, in honor of his seventieth birthday anniversary.——Dr. Levi F. Wagner, Pikesville, has moved to Reading.——Dr. Frederick E. Jenkins, Carbondale, has returned from the Philippines and is stationed at Fort Morgan, near Mobile, Ala.—Dr. Isaac Ohlman, Meadville, has decided to locate in Pittsburg.——Dr. John L. Wright, physician for the Pennsylvania Relief Association at Erie, has been transferred to Pittsburg.

Philadelphia.

Five Philadelphia hospitals receive $5000 each by the will of the late Thomas Elkinton of Philadelphia.

Smallpox.—This year there have been 287 cases of smallpox, with 36 deaths. Sixty new cases were reported during the last week and the municipal hospital now has more than 150 patients.

Personal.—Dr. S. Ashton Bonnaffon, of the Pennsylvania Relief Association, has been transferred to Erie.——Dr. Samuel McCullagh has resigned as resident physician of Girard College, and Dr. Henry G. Godfrey has been elected his successor.

Wills Hospital Changes.—Dr. William F. Norris has resigned after thirty years' service, as attending surgeon. Dr. John N. Kirk has been appointed resident physician, Dr. Paul J. Pontius, assistant surgeon, and Dr. George C. Harlan, consulting surgeon. Dr. William Zentmayer has been appointed attending surgeon, vice Dr. Norris, resigned.

CANADA.

G. M. McMicking, M.D., McGill, 1849, died, October 13, at his home in Toronto, aged 76. He practiced in Chippewa until 1867, and afterwards in Goderich for twenty-two years. He was a member of the legislature for twenty-two years.

Protestant Hospital for the Insane at Quebec.—The quarterly report of this hospital shows that 40 patients were admitted during that time, and that 13 had been discharged therefrom; 10 deaths occurred. The number at present undergoing treatment in this institution is 403.

Typhoid Among Troops.—Several of the officers and men of the Duke of York's Hussars, at Montreal, are suffering from attacks of typhoid fever. It is thought that the infection occurred at Quebec City, where the corps was participating in the arrival of the Duke and Duchess of Cornwall and York.

Canadian Nurses' Association.—The annual meeting of this Association was held in Montreal, on Tuesday evening, the 15th inst., Miss Rogers, the President, in the chair. The number of registrations reached 1034. During the present year the Association was incorporated by provincial charter.

Hotel Dieu Hospital, Montreal.—Hotel Dieu, the oldest hospital in the City of Montreal, has decided to establish a training school for nurses, so that hereafter French-Canadians and Catholics will not be dependent upon English institutions for trained nurses. The public will be appealed to for assistance in the project.

Personal.—Dr. Harry W. Spence, of Toronto, who has been taking a post-graduate course in England, has been successful in obtaining the degrees L.R.C.P. London, and M.R.C.S. England, and has been appointed surgeon on the steamer *Mombasa*, one of the British India Steamship Company's passenger steamers from London to Calcutta.

Correspondence.

Regarding Propagation.

Chicago, Oct. 8, 1901.

To the Editor:—In the discussion of Dr. George J. Englemann's interesting paper on the "Increasing Sterility of American Women," reported in The Journal for October 5, there are exhibited a depth of concern and a degree of alarm that do not seem to be warranted by those disclosures in the Doctor's paper which furnished the material for the greater part of the discussion.

The chief facts shown in the paper are, that sterility has increased rapidly during the last century; that the present average percentage of childless marriages in this country is about twenty; that the average number of children per married couple is 1.8, and that the chief causes of this increasing sterility and diminishing fecundity are the intentional prevention of conception and interruption of gestation.

These are intensely interesting facts, and the labor which their accumulation must have cost the author, entitles him to the highest praise. It may also be conceded without argument that the condemnation which the professional abortionist, the advertiser of abortifacients, and the male distributers of Neisser's diplococci, received at the hands of those who discussed the paper, was entirely just. But the mere facts that 20 per cent. of American marriages are childless, and that the number of children per married couple is only 1.8, do not seem to warrant the alarm that was exhibited in their discussion.

If these facts forebode a danger that constitutes sufficient grounds for alarm, this danger must be one which menaces either ourselves and our actual descendants, or those potential individuals of the future whose actual existence is prevented by our increasing infecundity. There can be no danger that threatens any one else.

What danger is there in these facts for us or our descendants? Would the struggle for existence be easier, or the joy of living greater, if there were more people in America or in the world? Is there any profession, trade, or calling that is not already enormously overcrowded? If we need more tillers of the soil, why has the exodus from the country to the town gone so swiftly forward that 47.1 per cent. of our present population is in incorporated towns and cities? If there is, on the other hand, a village, town, or city in America that needs more people than it has, why is it necessary for so great a part of the existing urban population to live in tenements (which, by courtesy, are called flats), and support families on $6.00 a week? Every new child born into the world is a prospective competitor of those already here. It must elbow its unwelcome way into an already overcrowded world, in which it will find no nook or corner fit to live in that is not already occupied, and no vocation from whose representatives it will receive a welcome. Let us be frank and admit that, for us and our descendants, there is encouragement rather than peril in the alleged diminution of our rate of increase.

Taking the other horn of the dilemma, we shall find it equally ridiculous to talk of doing missionary work in the interests of possible children that have never even begun to be. It is here assumed that a child "begins to be" at the moment of conception.

According to Henle's estimate, every woman produces 72,000 ova, each one of which is susceptible of fecundation and capable of development into a mature human being. Every one of these ova that fails to become fecundated becomes a dead human possibility. Should we endeavor to bring about the fecundation of all? If not of all, who shall decide how many?

Let us again be frank and admit that, until we shall have ameliorated the condition of the actually existent, we need not concern ourselves with the fate of these shadowy hosts of the merely potentially existent. We may go still further and insist that it is not necessary to countenance abortion, to be able to say that a marriage which is comparatively barren of children, may still be prolific of happiness, and that to make the propagation of the species the sole aim of marriage, is to degrade that institution to the spiritual level of a breeding farm.

Indeed, in normal cases, it is questionable whether the definite desire for children ever is a motive to marry. Love of the consort certainly long precedes the desire for children, and is a sufficient inducement to insure the perpetuation of the race. Desire for children comes later; for Nature has a way of accomplishing her mysterious purposes by appearing to let us do what pleases us, and then pleasing us with what she has enticed us into doing against our wishes.

A. C. McClanahan, M.D.

Book Notices.

Introduction to the Differential Diagnosis of the Separate Forms of Gallstone Disease, Based upon his own Experience Gained in 433 Laparotomies for Gallstones. By Professor Hans Kehr, Halberstadt. Authorized Translation by William Wotkyns Seymour, A.B. Yale, M.D. Harvard, Formerly Professor of Gynecology in the University of Vermont. (With an introduction by Prof. Kehr. Cloth. Pp. 370. Price, $2.50. Philadelphia: P. Blakiston's Sons & Co. 1901.

The literature of gallstone surgery in our language of late years has become quite considerable. Nevertheless, the addition of this translation from a leading German work on the subject will be of value to American readers. There is no question as to the importance of the subject and if the operative treatment of these conditions has not become so extensive in this country as it has in Germany, as hinted in the preface, the book will doubtless serve to bring about this desirable result. Professor Kehr has himself added a preface to this American edition in which he gives his views as revised from his latest experiences. In the selection of operative methods he employs cystectomy with drainage in this condition more and more. In this way he says we avoid more certainly true and false recurrences. Professor Seymour has given us an intelligent translation, but it contains a great many German constructions and can not be said to be quite as elegant English as it might be. Still, it is hard for a person who reads German much or little to avoid such slips occasionally in the translation of a language so difficult as German.

The Estivo-Autumnal (Remittent) Malarial Fevers. By Charles F. Craig, M.D. (Yale), Acting Assistant-Surgeon, U. S. A. Illustrated by 2 Colored Plates and 21 Clinical Charts. Cloth. Pp. 221. Price, $2.50. New York: William Wood & Co. 1901.

The author has given us in detail a description of certain fevers too little understood by the great mass of the profession. The opportunity presented to him while he was connected with military hospitals at home as well as in Cuba and the Philippines, was well utilized in a systematic and scientific study of the malarial diseases in their protean aspects, the result of which is published in this volume. He gives us an account of the estivo-autumnal parasites, describes them, giving their natural history, or life cycle within the mosquito, their varieties, method of staining, examination, etc. The etiology, pathology, diagnosis, prognosis, treatment, methods of infection, etc., of malaria are fully considered. The book is a most interesting addition to the literature on the subject and will be found invaluable to those who are desirous of understanding and thoroughly mastering the facts in regard to malaria. The manner in which the author has presented the subject is commendable in that it is simple yet scientific.

Manual of the Diseases of Children. By John Madison Taylor, A.M., M.D., Professor of Diseases of Children, Philadelphia Polyclinic, and William H. Wells, M.D., Adjunct Professor of Obstetrics and Diseases of Infancy in the Philadelphia Polyclinic. Second Edition, Thoroughly Revised and Enlarged. Illustrated. Cloth. Pp. 859. Price, $4.50. Philadelphia: P. Blakiston's Son & Co. 1901.

The authors have thoroughly rewritten their work, adding a number of new chapters and special articles. One of the points

Montreal General Hospital.—The governors of this institution have declined an offer of $25,000 for twenty thousand feet of land adjoining the present site of the General Hospital. Dr. J. B. McConnell presented the report of the management committee. The receipts from May 15 to October 9, amounted to $5015, and the expenditure $5719. The debt remains about the same as at the annual meeting, viz., $7948.

School Children and Vaccination.—The officials of the Health Department of Montreal are making special efforts to ascertain if pupils attending the public schools are being properly vaccinated, owing to the appearance once more in that city of the dread disease, and also on account of there being so many cases of smallpox in the province. As vaccination is not compulsory in the Province of Quebec, an effort will be made when the legislature meets to make it so.

Conference on Smallpox.—Dr. P. H. Bryce, secretary of the Ontario Board of Health, and Dr. Pelletier, secretary of the Quebec Board of Health, held a conference with the local board of health, at Ottawa, on the 14th inst., with regard to the epidemic of smallpox in that city. It is a noteworthy fact that out of the first twenty-four cases of smallpox reported, but one had previously been vaccinated. There have been thirty-four cases in all; the outbreak is now well under control.

Failure of the Physicians' and Surgeons' Supply Company.—Some months ago mention was made in these columns of the formation in Ontario of a supply company of the above description for practitioners in this province. It was thought at the time the association was organized that physicians were not receiving fair treatment at the hands of the drug trade. The organization was perfected in November last; the company began business in March of the present year. A directorate of physicians controlled the affairs of the company, which is now being wound up.

Medical Graduates and the Army.—Cable dispatches record that a Canadian medical graduate has been refused permission to serve on the British Medical Staff in South Africa; and the action of the home authorities in this connection is raising in the minds of military surgeons the question: What has become of the promised imperial legislation to permit duly qualified and certificated graduates of colonial medical colleges to enter the imperial service? Some months ago the Militia Department at Ottawa was notified that an act of this character had been introduced into the imperial parliament, but since that time nothing more has been heard of the matter; and it is not known whether the promised legislation passed into law or was thought to be a too generous concession to colonial medical graduates.

FOREIGN.

Plague at Rio Janeiro.—Two new cases of bubonic plague were found October 19, and three on the 20th, making 52 cases at the present time in the hospital.

Physician Contracts Leprosy.—Dr. Feilberg, city physician of Copenhagen, has contracted anesthetic leprosy. He had recently visited the West Indies.

Leper Hospital in Iceland.—The Order of Odd Fellows in Denmark established the Laugarnoes Hospital for lepers, October, 1898. At the end of 1899, 81 patients had been received, of which 18 are dead, and 2 have been discharged as cured.

The International Congress for Obstetrics and Gynecology will be held in Italy in 1902. The Russians have made great efforts to secure the congress in honor of the completion of the Academy for Obstetrics and Gynecology at St. Petersburg, the only institution of its kind in the world, our foreign exchanges assert. It has been erected under Ott's supervision by funds supplied by the Czar. The congress committee, however, had already made arrangements for the meeting in Italy. The first congress was held in Brussels, the second in Geneva and the third in Amsterdam.

International Congress of Tropical Diseases.—The Egyptian Medical Congress announced to convene at Cairo in December, 1902, will be practically a congress of tropical diseases, and the committee in charge would be glad to enlarge its scope and announce it as an international congress for this purpose. The realization of this project, however, they know depends on the co-operation of those interested in epidemiology and tropical pathology the world over, and they scarcely venture to hope for this. The list of communications already announced includes studies of the diseases, etc., prevalent in Egypt and Ethiopia, divided into three sections, medicine, surgery and ophthalmology.

PARIS LETTER.

President McKinley's death has been the cause of various comments on the part of the medical and political press in France. There has been quite a diversity of opinion shown, and it would seem as if the political newspapers had tried to cast doubts upon the manner in which the treatment was carried out. Certain medical men, hiding behind a pseudonym, and signing themselves with an X., have given forth views which showed their lack of appreciation of the difficulties to be encountered in the treatment of so desperate an injury. On the other hand, in the medical papers of good standing, the quickness with which a decision was come to has been much praised, and it has been repeatedly said that nowhere but in America such ready adaptability to the requirements of the time could have been found. There was, however, one fact, which impressed all medical men having some knowledge of the course observed in penetrating wounds of the abdomen, and that was the highly optimistic tendency of the bulletins issued.

Rabies.

The last statistics of the Pasteur Institute show how beneficial the treatment of rabies by inoculation has become. According to Tardieu, Thamhayn and Bouley, out of 855 cases of people bitten by mad dogs and who were not treated, death took place in 46.6 per cent. of the cases. The physicians of Alfort, Toulouse, Lyons and Berlin consider that about a third of the patients bitten by animals suffering from rabies are affected later with hydrophobia. On the other hand, in 1886, the first year the new treatment was tried, 2671 patients were inoculated at the Pasteur Institute and only 25 died, which makes a percentage of 0.94 per cent. In the last three years, 1898, 1899, 1900, 4499 persons were treated by this method and only 11 died, which makes the very low record of 0.25 per cent. Roux and Nocard's researches have shown that if, after three or four days, the dog suspected of rabies has shown no specific symptoms, the person who has been bitten is running no danger of infection. The disease itself runs a course of 10 days, so this is a means of making the diagnosis.

Epidemic of Smallpox.

Dr. Roger, physician of the Aubervilliers smallpox hospital, has just published the statistics of the cases of smallpox in Paris during the first six months of the year. There were in all 1996 cases with 274 deaths. There were over a hundred cases in the 20th and 23d week. Certain parts of Paris have been singularly free from the epidemic, such as the Champs-Elysées quarter where there were only 23 cases. The neighborhood of hospitals seems to be particularly disadvantageous, the two quarters around the Aubervilliers and the Pasteur Hospital having the greatest number of cases, 258 and 360. The mortality in Dr. Roger's service is 24 per cent., which is rather large. There seems to be at present a smaller number of cases, but Dr. Roger does not consider that the epidemic is over and he recommends vaccination every three years, as numerous facts collected during the recent epidemic show that the immunity is of much shorter duration than was at first imagined.

Congress of Gynecology and Obstetrics.

At the recent Congress of Gynecology and Obstetrics held at Nantes, Dr. Baudron of Paris spoke of the method he used, which consists in simple dilatation, in cases of uterine anteflexion with dysmenorrhea and sterility. He compared it to the other methods used, such as hysterotomy or ventrofixation.

Dr. Varnier made a report on the treatment of uterine rupture and described the results obtained by the old methods, such as extraction of the child and tamponing, and others obtained of recent date by laparotomy. The latter are much better and Dr. Varnier said that it was hard to decide after manual examination per vaginam, if rupture was complete or incomplete. The best course to follow was immediate laparotomy. Professor Pinaud insisted on the dangers of uterine rupture; some cases did not seem at first so alarming. He advocated immediate laparotomy in all cases. Dr. Pinaud also spoke on the use of aniodol as an antiseptic. He has been using it extensively in his service at the Clinique Baudelocque, and has found that it can be used in washing the eyes of the newborn infants.

Artificial Horse Bites.—A French exchange states that a new means of defrauding the public has recently been discovered in Paris. An instrument was made which produced a wound resembling the bite of a horse and damages were claimed from the owner of the horse incriminated as the assailant.

Correspondence.

Regarding Propagation.

Chicago, Oct. 8, 1901.

To the Editor:—In the discussion of Dr. George J. Englemann's interesting paper on the "Increasing Sterility of American Women," reported in The Journal for October 5, there are exhibited a depth of concern and a degree of alarm that do not seem to be warranted by those disclosures in the Doctor's paper which furnished the material for the greater part of the discussion.

The chief facts shown in the paper are, that sterility has increased rapidly during the last century; that the present average percentage of childless marriages in this country is about twenty; that the average number of children per married couple is 1.8, and that the chief causes of this increasing sterility and diminishing fecundity are the intentional prevention of conception and interruption of gestation.

These are intensely interesting facts, and the labor which their accumulation must have cost the author, entitles him to the highest praise. It may also be conceded without argument that the condemnation which the professional abortionist, the advertiser of abortifacients, and the male distributers of Neisser's diplococci, received at the hands of those who discussed the paper, was entirely just. But the mere facts that 20 per cent. of American marriages are childless, and that the number of children per married couple is only 1.8, do not seem to warrant the alarm that was exhibited in their discussion.

If these facts forebode a danger that constitutes sufficient grounds for alarm, this danger must be one which menaces either ourselves and our actual descendants, or those potential individuals of the future whose actual existence is prevented by our increasing infecundity. There can be no danger that threatens any one else.

What danger is there in these facts for us or our descendants? Would the struggle for existence be easier, or the joy of living greater, if there were more people in America or in the world? Is there any profession, trade, or calling that is not already enormously overcrowded? If we need more tillers of the soil, why has the exodus from the country to the town gone so swiftly forward that 47.1 per cent. of our present population is in incorporated towns and cities? If there is, on the other hand, a village, town, or city in America that needs more people than it has, why is it necessary for so great a part of the existing urban population to live in tenements (which, by courtesy, are called flats), and support families on $6.00 a week? Every new child born into the world is a prospective competitor of those already here. It must elbow its unwelcome way into an already overcrowded world. in which it will find no nook or corner fit to live in that is not already occupied, and no vocation from whose representatives it will receive a welcome. Let us be frank and admit that, for us and our descendants, there is encouragement rather than peril in the alleged diminution of our rate of increase.

Taking the other horn of the dilemma, we shall find it equally ridiculous to talk of doing missionary work in the interests of possible children that have never even begun to be. It is here assumed that a child "begins to be" at the moment of conception.

According to Henle's estimate, every woman produces 72,000 ova, each one of which is susceptible of fecundation and capable of development into a mature human being. Every one of these ova that fails to become fecundated becomes a dead human possibility. Should we endeavor to bring about the fecundation of all? If not of all, who shall decide how many?

Let us again be frank and admit that, until we shall have ameliorated the condition of the actually existent, we need not concern ourselves with the fate of these shadowy hosts of the merely potentially existent. We may go still further and insist that it is not necessary to countenance abortion, to be able to say that a marriage which is comparatively barren of children, may still be prolific of happiness, and that to make the propagation of the species the sole aim of marriage, is to degrade that institution to the spiritual level of a breeding farm.

Indeed, in normal cases, it is questionable whether the definite desire for children ever is a motive to marry. Love of the consort certainly long precedes the desire for children, and is a sufficient inducement to insure the perpetuation of the race. Desire for children comes later; for Nature has a way of accomplishing her mysterious purposes by appearing to let us do what pleases us, and then pleasing us with what she has enticed us into doing against our wishes.

A. C. McClanahan, M.D.

Book Notices.

Introduction to the Differential Diagnosis of the Separate Forms of Gallstone Disease, Based upon his own Experience Gained in 433 Laparotomies for Gallstones. By Professor Hans Kehr, Halberstadt. Authorized Translation by William Wotkyns Seymour, A.B. Yale, M.D. Harvard, Formerly Professor of Gynecology in the University of Vermont. With an introduction by Prof. Kehr. Cloth. Pp. 370. Price, $2.50. Philadelphia: P. Blakiston's Sons & Co. 1901.

The literature of gallstone surgery in our language of late years has become quite considerable. Nevertheless, the addition of this translation from a leading German work on the subject will be of value to American readers. There is no question as to the importance of the subject and if the operative treatment of these conditions has not become so extensive in this country as it has in Germany, as hinted in the preface, the book will doubtless serve to bring about this desirable result. Professor Kehr has himself added a preface to this American edition in which he gives his views as revised from his latest experiences. In the selection of operative methods he employs cystectomy with drainage in this condition more and more. In this way he says we avoid more certainly true and false recurrences. Professor Seymour has given us an intelligent translation, but it contains a great many German constructions and can not be said to be quite as elegant English as it might be. Still, it is hard for a person who reads German much or little to avoid such slips occasionally in the translation of a language so difficult as German.

The Estivo-Autumnal (Remittent) Malarial Fevers. By Charles F. Craig, M.D. (Yale), Acting Assistant-Surgeon, U. S. A. Illustrated by 2 Colored Plates and 21 Clinical Charts. Cloth. Pp. 221. Price, $2.50. New York: William Wood & Co. 1901.

The author has given us in detail a description of certain fevers too little understood by the great mass of the profession. The opportunity presented to him while he was connected with military hospitals at home as well as in Cuba and the Philippines, was well utilized in a systematic and scientific study of the malarial diseases in their protean aspects, the result of which is published in this volume. He gives us an account of the estivo-autumnal parasites, describes them, giving their natural history, or life cycle within the mosquito, their varieties, method of staining, examination, etc. The etiology, pathology, diagnosis, prognosis, treatment, methods of infection, etc., of malaria are fully considered. The book is a most interesting addition to the literature on the subject and will be found invaluable to those who are desirous of understanding and thoroughly mastering the facts in regard to malaria. The manner in which the author has presented the subject is commendable in that it is simple yet scientific.

Manual of the Diseases of Children. By John Madison Taylor, A.M., M.D., Professor of Diseases of Children, Philadelphia Polyclinic, and William H. Wells, M.D., Adjunct Professor of Obstetrics and Diseases of Infancy in the Philadelphia Polyclinic. Second Edition, Thoroughly Revised and Enlarged. Illustrated. Cloth. Pp. 859. Price, $4.50. Philadelphia: P. Blakiston's Son & Co. 1901.

The authors have thoroughly rewritten their work, adding a number of new chapters and special articles. One of the points in which it will be found up to date is that of infant feeding, and still other matters are also well brought up. Much new matter has been added to the portions on diseases of the nervous system and respiratory disorders. A chapter on ear diseases, which is a very important matter in children, has been added.

Deaths and Obituaries.

J. G. Kerr, M.D., Jefferson Medical College, Philadelphia, 1847, who was one of the best known medical missionaries in China, died at his home in Canton, China, aged 77. He was born in Adams County, Ohio, and for a time practiced in this country, but the past forty-five years he had devoted to his work among the Chinese. He was eminent as an operator for urinary calculi, and in 1898 was called to operate upon the American Minister to China. During the last few years he established and superintended an asylum for the insane, something previously unknown in that country. He also accomplished much in his translations of medical works into Chinese for the use of the students.

Philip Goode Gillett, M.D., for many years superintendent of the Illinois Institution for the Education of Deaf Mutes, died at his home in Jacksonville, Ill., October 2, aged 67. He was connected with the above institution in a minor capacity during his student days and became interested in deaf mute work and devoted all his energies in that direction. He was the first to introduce instruction in articulation and lip reading in a state institution, and he brought about the establishment of the Illinois State Board of Charities.

George W. Burke, M.D., Jefferson Medical College, Philadelphia, 1866, died at his home in New Castle, Ind., October 18, from Bright's disease, aged 59. During the Civil war he was an assistant surgeon in the 46th Pennsylvania and later in the 20th Army Corps, serving until the close of the war. He practiced for a time at Sulphur Springs, Ind., but for the past thirty-five years had practiced at New Castle. He was a member of the American Medical Association.

Charles H. Brown, M.D., University of the City of New York, 1879, died at his home in New York City, October 15, aged 45. He was for many years the managing editor of *The Journal of Nervous and Mental Diseases* and was connected with the New York Dispensary, the Post-Graduate and the Presbyterian hospitals, and the outdoor work of Bellevue Hospital.

Donald R. Hinckley, M.D., Harvard Medical School, Boston, 1896, shot and killed himself, probably accidentally, while visiting his parents at Northampton, Mass., October 14. He was a graduate of Yale University in the class of '92, and had been in active practice at New Haven, Conn., having recently been appointed instructor in the Yale Medical School. He was aged 31.

Joseph H. Wythe, M.D., Philadelphia College of Medicine and Surgery, 1850, died at his home in Oakland, Cal., October 14, after a long illness, aged 79. He was born in Manchester, England, and during the Civil war was assistant surgeon. He remained in the army for a number of years after the close of the war, and, after resigning his commission, studied for the ministry.

Robert Henry Nesbitt, M.D., College of Physicians and Surgeons, New York, 1899, died, October 10, at the New York Hospital of which he was once an interne. He had just returned from Europe when he was seized with his fatal illness, a strangulation of the intestine. His home was at Wheeling, W. Va.

Hiram P. Tuttle, M.D., University of California, 1869, died at Tacoma, Wash., October 9. He retired in 1898 in order to devote his entire time to the perfection of thorite, a high explosive, for the purchase of which Congress had made an appropriation at its last session.

Horace Bigelow, M.D., College of Physicians and Surgeons, New York, 1896, died in Roosevelt Hospital, October 15, from typhoid pneumonia, aged 28. He was born in Fayetteville, N. Y., and at the time of his death was a member of the outdoor staff of the hospital named.

Henry Raymond Rogers, M.D., Jefferson Medical College, Philadelphia, 1851, died at his home in Dunkirk, N. Y., October 19, aged 79. He retired from practice several years ago for scientific and literary work. As a writer he was noted for his original views.

Porter W. Felt, M.D., Detroit College of Medicine, 1882, died at his home in Belleville, Mich., where he had practiced for the past twenty years, October 12, from the result of an overdose of morphin, taken, it is believed, by accident. He was aged 44.

William W. Duval, M.D., University of Maryland, Baltimore, 1843, died at his residence, Gladswood, Prince George County, Md., October 13, aged 80. He was president of the county school board and identified for forty years with public education.

Hannah E. Longshore, M.D., Woman's Medical College, Pennsylvania, 1851, died in Philadelphia, October 18, aged 82. She was the first woman to practice medicine in the city named and served as a demonstrator of anatomy.

William G. Fisher, M.D., Medical Department Washington University, St. Louis, 1866, died at his home in Marshall, Mo., October 9, aged 57. He practiced for a number of years at Napton, Mo., moving to Marshall in 1896.

Herbert J. Hale, M.D., Detroit Medical College, 1875, died at his home in Grass Lake, Mich., October 3. At its recent meeting the Jackson County (Mich.) Medical Society passed resolutions of respect for his memory.

John Semple, M.D., Jefferson Medical College, Philadelphia, 1848, died at his home in Wilkinsburg, Pa., October 9, after an illness of two weeks, aged 80. He was burgess of Wilkinsburg from 1888 to 1890.

Frederick Loeber, M.D., New Orleans School of Medicine, 1866, died at his home in New Orleans, October 18, aged 63. He was for thirty-one years the head of the Touro Infirmary and was a prominent physician.

Samuel Edward Stiles, M.D., Long Island College Hospital, New York, 1870, died in Brooklyn, N. Y., October 9, aged 67. He was a noted genealogist and retired from active practice some years ago.

Wesley A. Vineyard, M.D., Tennessee Medical College, Knoxville, 1890, died at his home in Luttrell, Tenn., October 9, from heart failure, aged 41. He was a representative to the Legislature in 1900.

Edwin T. Edgerton, M.D., Pennsylvania Medical College, Philadelphia, 1851, died at his home in Saline, La., October 14, from the effects of a cancer, aged 75. He was a native of South Carolina.

Chester L. Gross, M.D., Jefferson Medical College, Philadelphia, 1861, died suddenly at his home in Pen Argyl, Pa., October 9, aged 65. He formerly practiced at Freemansburg.

Ernest Schottky, M.D., College of Physicians and Surgeons, New York, died at his home in Passaic, N. J., October 18, aged 56. He at one time resided in New York City.

William L. Harding, M.D., New York University, 1860, died at his home in New York City, October 11. He was a surgeon in the Union army during the Civil war.

Charles W. Lawrence, Jr., M.D., University of Tulane, New Orleans, 1900, died at his home in Longview, Texas, from typhoid fever, October 4.

J. H. Tabler, M.D., University of Tennessee, Nashville, 1892, died at his home in Lawrenceburg, Tenn., October 13, after a brief illness.

Jefferson M. Mason, M.D., University of Arkansas, Little Rock, 1888, died at his in Floresville, Texas, October 12, after a long illness.

W. A. Withers, M.D., Rush Medical College, Chicago, 1898, died at his home in New Orleans, October 14, after a long illness.

Societies.

COMING MEETINGS.

Medical Society of Virginia, Lynchburg, Nov. 5-7, 1901.

Oklahoma Territory Medical Association, Oklahoma City, Nov. 13, 1901.

Southern Surgical and Gynecological Association, Richmond, Va., Nov. 12-14, 1901.

Western Surgical and Gynecological Association, Chicago, Dec. 18-19, 1901.

Southern California Medical Society will meet at Los Angeles, December 4 and 5.

Central Medical Association.—At a meeting of this Association, held at Middletown, Conn., October 7, it was voted to retain the same officers for the coming year.

Holyoke (Mass.) Medical Society.—This Society met October 7 and elected Dr. C. A. Allen, president, Dr. D. F. Donoghue, vice-president, and Dr. J. J. McCabe, secretary-treasurer.

Inland Empire Clinical Society.—This Society was recently recognized by and affiliated with the Idaho State Society, thus giving the former the full privileges of a country or district medical association.

Guthrie (Okla.) Medical Society.—At a meeting of this Society, October 7, the following officers were elected: Dr. R. V. Smith, president; Dr. J. L. Melvin, vice-president, and Dr. E. O. Barker, secretary-treasurer.

Idaho State Medical Society.—The ninth annual meeting of this Society was held at Pocatello, October 3 and 4, and Dr. Hubert A. Castle, Pocatello, was elected president, and Dr. Ed. E. Maxey, Caldwell, re-elected secretary-treasurer.

Southern Manitoba Medical Society.—This Society was organized at Napinka, October 9, and the following officers elected: President, Dr. E. J. McConnell, Morden; vice-president, Dr. Frederick L. Schaffner, Boissevan, and secretary-treasurer, Dr. T. J. Lamont, Treherne.

Detroit (Mich.) Academy of Medicine.—The regular meeting of this Academy was held, October 8, and Dr. Arthur D. Holmes was re-elected to the presidency; other officers elected were Dr. Wadsworth Warren, vice-president, and Dr. Harrison D. Jenks, secretary-treasurer.

McKean County (Pa.) Medical Society.—At the meeting of this Society held in Bradford, October 8, the officers elected were as follows: Dr. William P. Burdick, Mt. Jewett, president; Dr. James C. Walker, Bradford, vice-president, and Dr. B. H. Hall, Bradford, secretary-treasurer.

Stafford District (N. H.) Medical Society.—The ninety-fourth annual meeting of this Society was held at Dover, October 9, and the following officers elected: President, Dr. William H. Nute, Exeter; secretary, Dr. Lewis W. Flanders, Dover, and treasurer, Dr. John R. Ham, Dover.

White County (Ill.) Medical Association.—At the regular meeting of this Association, at Grayville, October 15, the following officers were elected: President, Dr. V. H. Parker, Grayville; vice-presidents, Drs. J. N. Hopkins, Burnt Prairie, and I. A. Foster, Herald; secretary-treasurer, Dr. W. A. Steele.

Fergus County (Mont.) Medical Association.—This Association was recently permanently organized with the following officers: President, Dr. J. B. Atchison, Lewiston; vice-president, Dr. W. A. Long, Lewiston; secretary, Dr. Frederick Treacy, Lewiston, and treasurer, Dr. C. A. Tillotson, Gilt Edge.

Jackson County (Mo.) Medical Society.—At the meeting of this Society, held in Kansas City, October 10, the following officers were elected: President, Dr. William Frick; vice-president, Dr. Walter S. Wheeler; secretary, Dr. Edward H. Thrailkill, and treasurer, Dr. Louis W. Luscher, all of Kansas City.

El Paso County (Texas) Medical Society.—At the third annual meeting of this Society, at El Paso, October 12, the following officers were elected: President, Dr. S. T. Turner; vice-president, Dr. W. N. Vilas; secretary, Dr. J. A. Rawlings (re-elected), and treasurer, Dr. H. E. Stevenson (re-elected), all of El Paso.

Corsicana (Texas) District Medical Association.—At the regular meeting of this Association, October 8, the following officers were elected: President, Dr. T. A. Miller; vice-presidents, Drs. T. L. Slater, Re, and M. L. Langford, Corsicana; secretary, Dr. W. D. Fountain, and treasurer, Dr. L. E. Retton, both of Corsicana.

Tennessee Valley Medical Association.—This Association met at Athens, Ala., October 8 and 9, and elected the following officers: President, Dr. Felix E. Baldridge, Huntsville; vice-presidents, Drs. F. P. Pettey, New Decatur, and T. E. Casey, Albertsville; secretary, Dr. Thomas E. Dryer, Huntsville, and treasurer, Dr. Edgar Rand, Huntsville.

Cedar Falls (Iowa) Medical Society.—The annual meeting of this Society was held at Cedar Falls, October 8 and 9, and the following officers were elected: President, Dr. George B. Thompson, Winthrop; vice-president, D. M. Wick, Cedar Falls; secretary, Dr. T. U. McManus, Waterloo, and treasurer, Dr. R. E. Buchanan. The next meeting will be held in Waverly.

Jefferson County (Tenn.) Medical Society.—The physicians of this county met October 8 and reorganized this Society, which has been dormant for the past twenty years. The following officers were elected: Dr. I. M. Tittsworth, Jefferson City, president; Dr. C. L. Cline, White Pine, vice-president; Dr. S. W. Fain, secretary, and Dr. P. A. Tinsley, Dandridge, treasurer.

Medical Association of Northern New York.—At the meeting of this Association held at Plattsburg, October 8, the following officers were elected: President, Dr. Frank Madden, Plattsburg; vice-president, Dr. Walter S. Daly, Ogdensburg; treasurer, Dr. George H. Oliver Dickinson, and secretary, Dr. Alfred G. Wilding, Malone. Dr. Cassius D. Silver, Plattsburg, was elected delegate to the State Medical Association.

Albany County (N. Y.) Medical Association.—The members of the Second District Branch residing in Albany County met, October 9, and organized this Association, electing the following officers: President, Dr. Charles M. Culver, Albany; vice-president, Dr. Adam T. Van Vraken, Watervliet; secretary-treasurer, Dr. William B. Sabin, Watervliet; fellow, Dr. W. R. Lothridge, Verdoy, and alternate, Dr. John U. Haynes, Cohoes.

Tri-State Medical Society.—This Society, representing the states of Alabama, Georgia and Tennessee, met at Nashville, October 8, 9 and 10, and the following officers were elected: President, Dr. John C. LeGrand, Birmingham; vice-presidents, Drs. Pugh U. Brown, Troy, Ala., William P. Harbin, Rome, Ga., and James C. Wilson, Rockwood, Tenn.; secretary, Dr. Frank T. Smith, and treasurer, Dr. George R. West, both of Chattanooga. The next place of meeting is Birmingham, Ala.

San Joaquin Valley Medical Association.—At the annual meeting of this Association, held in Stockton, Cal., October 8, the following officers were elected: President, Dr. Henry Hildreth, Delano; vice-presidents, Drs. B. F. Surrhayne, Modesto, J. L. Carson, Bakersfield, and J. B. Rosson, Tulare; secretary, Dr. W. S. Fowler, Bakersfield; assistant secretary, Dr. D. B. Trowbridge, Fresno, and treasurer, Dr. T. M. Hayden, Fresno. The next meeting will be held in Fresno, the second Tuesday in March, 1902.

Wyoming State Medical Society.—The fifth annual meeting of this Society was held at Evanston, October 8 and 9, and the following officers were elected: President, Dr. G. G. Verbryck, Cambria; vice-presidents, Drs. F. H. Harrison, Evanston, W. C. Burk, Rock Springs, and W. A. Wyman, Cheyenne; secretary, Dr. C. H. Solier, Evanston; treasurer, Dr. J. L. Wicks, Evanston; delegate to the American Medical Association, Dr. R. Harvey Reed, Rock Springs; alternate, Dr. E. E. Lewis, Spring Valley. The next place of meeting was fixed for Cheyenne in joint session with the Rocky Mountain Interstate Medical Association.

Vermont State Medical Association.—The eighty-eighth annual meeting of this Association was held in Montpelier, October 10 and 11, and it was voted unanimously to reorganize on a basis of the county medical societies, that is, to establish in each county a society in affiliation with the State Association; a committee of three, consisting of Drs. D. C. Hawley, Burlington, J. M. Hamilton, Rutland, and W. D. Huntington, Rochester, was appointed to complete the organization throughout the state, and were empowered to employ one of their own number or any other member in good standing as organizer to visit the various counties. The following officers were elected for the coming year: President, Dr. J. B. Wheeler, Burlington; vice-president, Dr. M. F. McGuire, Montpelier; secretary, Dr. G. H. Gorham, Bellows Falls, and treasurer, Dr. J. W. Avery, Proctor. Burlington was selected as the next place of meeting.

CINCINNATI ACADEMY OF MEDICINE.

Regular Meeting, Oct. 7, 1901.

President Dr. N. P. Dandridge in the Chair.

Discussion on Major Wm. O. Owen's Paper.

Dr. P. S. Connor (medical member of the commission appointed by President McKinley to investigate the conduct of the Spanish-American War) opened the discussion on Major Wm. O. Owen's paper, "Preventable Disease in the Army of the United States; Cause, Effect and Remedy." He stated that many of the lessons which the Civil war had taught seemed to have been forgotten in the Spanish-American war. It was certainly possible to have prevented many of the diseases, particularly typhoid fever, but unfortunately preventive measures were not instituted in time. He stated that in many instances the seeds of typhoid fever were carried into the camps from the starting points of the troops, and that the soldiers were not infected so much from the camps established later. Then again crowd poisoning was a potent factor in breeding disease. A large part of the medical force was unfamiliar with military matters and camp sanitation. Sinks, in Camp Thomas, for instance, were not dug until ten days after the troops arrived, and when dug were soon allowed to fill up and overflow. Everything that was unsanitary, it seemed, existed at Camp Thomas. And what was true of this camp was true of many others to a greater or less degree. If troops could have been kept in small companies, thoroughly isolated and inspected regularly, nothing like the amount of sickness would have occurred. The morale of the camps was bad, and the country will suffer for many years from the results of the diseases engendered in these camps; pension grants will increase materially from year to year.

The responsibility for disease should be established, but as to how we are to get out of the existing difficulties he did not know. Reform should begin with the Medical Department, and not with a medical officer here and there. Medical officers have not enough authority. Give them authority along the lines of sanitation, inspection of troops, medical supplies, etc., and then hold them responsible for any dereliction of duty along these lines. Nothing in the way of reform can be accomplished unless the movement begins in the Medical Department of the army. Unquestionably the Medical Department should have its own transportation. Many times supplies arrived at their destination but could not be gotten out of the cars without orders; in other instances supplies that were started promptly on their way did not arrive at all. In conclusion, Mr. Connor said that everybody realized the necessity for radical changes in the Army Medical Department, but thought that nothing would ever be accomplished through resolutions passed by different medical societies throughout the country. It was unfortunately true that a word from one of the dozen prominent politicians who could be named would carry more weight and be more liable to accomplish results than the resolutions of all the medical societies of the country. Finally, considering all the circumstances connected with the Spanish-American war, it was wonderful that the Medical Department got along as well as it did, and that there were not more lives sacrificed.

Dr. S. P. Kramer (major and surgeon, U. S. Volunteers, Spanish-American war) stated that sufficient time had not elapsed since the war, for the people to calmly think over the lessons to be learned from experience. Many adverse criticisms had been made of the Medical Department, some of which were no doubt just, but it must be remembered that the causes leading to such criticism were and are just as rife in civil life as in the army. He had listened during the evening to a good deal of criticism of army regulations, but to him army regulations were a necessity, and red-tape an essential part of the system; the regulations of the United States Army were the compilation of the experiences of men who had seen years of service and were therefore fully competent to formulate plans for the guidance of the army. As in civil, so in army life, a great deal depends upon the individual. He himself had had no trouble in obtaining medical supplies, but he knew those who did, and in many such cases the fault was with the medical officer. Some of them wasted supplies; others did not go about obtaining them in the right way. The causation of typhoid fever was due to the unsanitary condition of the camps; the remedy for this was education along the line of sanitation, and if the laws of governing this branch of camp equipment should be violated the offender should be severely punished. He wished to offer the suggestion that many of the so-called laws of sanitary science were by no means thoroughly worked out, and that officers of the line could not be very severely blamed for not following what were to them, at the best, but theories. But he thought that such of the laws of the science as were known should be taught officers of the line at the military academy at West Point. He thought Major Owen was right in bringing this matter before the authorities, and likened him unto a wedge which would be considerably hammered and the edge taken off it, for his temerity in forcing these unwelcome truths upon the army. Contract surgeons, he said, occupied a very anomalous position; they have no responsibility; practically they can resign after giving two weeks' notice; they are exposed to all the risks a regularly appointed medical officer runs; they are not in the line of promotion, and they have not the authority of the regularly appointed medical officer, which is little enough, it is true. Under such disadvantages the service does not get the best there is in these men. In conclusion, Dr. Kramer stated that notwithstanding all the disadvantages under which the army corps labored, the mortality from typhoid fever was but little, if any, greater than that obtained in private practice or in the large public hospitals of civil practice.

Dr. Byron Stanton (late major and surgeon, U. S. Volunteers, 1861-65) said that the paper of Major Owen strongly impressed what has been often said, that it is not the carnage of battle, but the pestilence that lurks in the camps, that is most to be feared. It is a sad commentary on the management of our troops that so large a per cent. of the deaths should have been from typhoid fever, a disease more easily prevented than any other except smallpox. When nearly 22 per cent. of the soldiers, selected, as Dr. Owen has said, from among the flower of young American manhood, suffer from a preventable disease there must be something wrong with those in authority. I am sure that the figures given are not exaggerations. I believe it to be an underestimate, although coming from official sources. The investigations of the commission consisting of Drs. Walter Reed, E. O. Shakespere and Victor C. Vaughan, appointed to study the causes and spread of typhoid fever among the troops at various camps in the United States during the Spanish-American war, show that many of the cases returned under the head of diarrhea, continued fever and malaria, were undoubtedly cases of typhoid fever. The report of Dr. Vaughan, one of the commission, shows that more than 80 per cent. of the deaths from the Spanish-American war were from typhoid fever. That much of the mortality might have been prevented by means known to sanitarians, I fully believe. During the Civil war the per cent. of mortality from the preventable diseases was, no doubt, greater, but at that time much less was known about preventive medicine than was known in 1898 and 1899.

With the advance in sanitary knowledge greater responsibility rests upon those having charge of camps and troops. The application of knowledge now in possession of sanitarians has resulted in a marked diminution in the last decade in the mortality of cities and towns, amounting to 180 in 1,000,000 of population, as shown by the vital statistics published by the U. S. Census Bureau. The application of the same knowledge to camp sanitation would have resulted in a greater saving of life among the soldiers. By means known to sanitarians before the outbreak of the late war, the death-rate should have been greatly lessened. That knowledge was not possessed by other officers though known to and urged upon them by the Medical Corps of the Army, but with the indifference to advice from medical sources, even in regard to medical matters, that is characteristic of the average commanding officer, the most threatening danger of camp-life—filth—was permitted to exist. Waste was not safely and duly disposed of, consequently there was contamination of water supplies, and the other known means of communicating typhoid fever were present. The spread of typhoid fever is generally attributed to the use of water contaminated by the feces of typhoid patients, and this is, no doubt, the chief cause of its spread, but it is not the only cause. Air-borne typhoid is of more common occurrence than has generally been supposed. This is especially true among soldiers. Other sources of infection than water contaminated with feces, are here more potent than in civil life. The dangers intensified by army life are as follows: Water contamination by the urine of typhoid patients, an undoubted source of danger; contamination of the camp with fecal matter, which permits the carriage of the bacillus by dust; the use of shallow, open sinks by typhoid patients without disinfection of the dejecta, which renders possible the carrying of contagion by flies, an often present and too much overlooked source of danger; hospital contagion, a danger greater than is generally supposed; the sleeping of the ambulant cases in the company tents, through which the bedding, clothing and tentage become contaminated; the use of the same cups and utensils, and lack of cleanliness on the part of cooks. That there are other means of communicating typhoid fever than by the use of polluted water is shown by the result of moving a camp, the water supply remaining the same. A change of camp site, even for a short distance, is followed by a diminution of disease, especially typhoid.

The position taken by Major Owen is the correct one. Sanitary matters should be under the care of the medical officer. The prevention of disease is his first care. He can best make use of sanitary knowledge. The means for the prevention of disease are best known to him. Medical officers have a greater knowledge of all matters relating to camp and personal hygiene, and much should be entrusted to their care in the selection and maintenance of camps, except where the exigencies of war may prescribe the location of the troops. More of preventive medicine should be taught the medical officer and then much more should be required of him. He should be given more authority. To him should be entrusted the prevention or removal of all sources of camp pollution. Filth is a most threatening danger. The health of the army depends largely upon cleanliness, and the success of the campaign may depend upon the health and well-being of the troops. Sickness reduces the strength of an army not only by the loss of those who are sick, but by the detail for hospital duty. Aye, even more than this, the depressing influence of the presence of sickness affects the zeal, spirit and confidence of an army. Even those who are not sick are less efficient as soldiers. The medical officers whose duty it is "to investigate the sanitary condition of the post or command" should have something more than the mere privilege of making recommendations that they have no power to carry out—recommendations that the commanding officer, too often uninformed upon sanitary matters, may accept or reject. It is generally the latter, as instanced in the paper of Major Owen, which I most cordially commend.

Dr. Edwin Ricketts said that in no sense can it be claimed that this paper was a political move. It is to be commended for its teeming facts as to superior line officers' vested authority in matters that should be referred to the army surgeon, as superior medical authority, for advice before final decision. It steps forward and into bold relief and deserves much consideration by way of emphasis. It calls "attention" in no uncertain sound to the importance of preventive medicine in selecting army camp sites and in timely changing them, so soon as the army surgeon, who should be referee, sees the necessity of so doing, except when the camp site is held as a military necessity. Then the army surgeon should waive all other considerations. It is shown how much more deadly were the germs of typhoid fever and dysentery in the camps located in the United States, on account of lack of hygienic considerations, than were the bullets of an opposing army in the enemy's country, there being 3116 deaths from preventable diseases, as compared with 1070 for homicide, suicide and gunshot wounds. The cross-road physician would feel himself disgraced and with a ruined professional reputation if he had a mortality following his treatment of typhoid fever that came anywhere near this. The deplorably high mortality in typhoid fever and dysentery can not in justice be laid at the door of the army surgeon. Their results in treatment show a mortality of 7.60 per cent. of all cases. This mortality represents 86.24 per cent. of the total mortality of all diseases. The pleadings of the medical officers with their superiors of the line for a change in camp site were in vain. For these pleadings and suggestions they were to be chagrined and humiliated on account of the lack of consideration that should have been extended them. The fault of this lies within our own ranks, for we lack independence, dignity and determination in not demanding and seeing that we have extended to our profession due respect and due consideration for the services rendered to the service of the United States. Major Owen has proven to us fully the courage of his convictions and the cause for the faith that is in him, instead of remaining in the usual subordinate, submissive quietude of the average army surgeon. It has been wisely arranged by our government that any soldier, as soon as he is found to be suffering from tubercular infection, should be promptly isolated by being taken to one of the national farms for tuberculosis. These farms are especially located for the arrest and possible cure of the disease. On the other hand, the poor and unfortunate typhoid fever patient has been kept within an already infected hospital camp. It was safer to have been a private in the charge on San Juan Hill than to have been in Camp Meade, Camp Alger, Camp Thomas or even Camp Merritt, California. With the amended bill as suggested by Major Owen for presentation to Congress, could the tears of the 3116 mothers and those of the relatives and friends, be presented, I am sure it would have a hearing. Could the 3116 men have had the opportunity, they would have gladly and gallantly responded to the bugle's blast, calling them to the charge, even though every life of them had to be sacrificed. They would have accepted the inevitable as thousands of American soldiers have already done. The 3116 deaths from typhoid were from sanitary neglect. It was not excusable. It can not be condoned, for there was no enemy to fight, no enemy within a thousand miles. There could have been no military necessity in these places of assembly and instruction.

Dr. Frank W. Hendley (Late Surgeon and Major Ohio Volunteer Infantry), said that his observation, based upon acquaintance and conversation with a considerable number of surgeons of the army, was that they do not so much desire increased rank or pay as authority and power to enforce sanitary and hygienic measures. The possession of such authority and power would necessarily include the exclusive control of all property, and transportation of all hospitals, hospital corps, ambulance companies and other subdivisions of the medical service. The present status of the medical officer is well-nigh intolerable. As he can only recommend or make request, his efficiency depends upon the complacency of the line officer with whom he is associated. The medical officer may recognize a certain source of danger to the command and recommend certain action to obviate it, but unless the line officer in command concurs and acts in accordance with the recommendation the surgeon can do nothing except wait for the disaster that is to come and then cheerfully go to work to repair the damage.

At the outbreak of the Spanish-American war it was well known that smallpox existed in Cuba, where the troops were expected to operate; consequently the surgeons in all the regiments in Ohio and probably in all others, recommended vaccination during the period of mobilization, in order that the wounded arms might heal before the active camp life commenced. Fortunately, we had a colonel who recognized the propriety of the recommendation and concurred heartily, even going so far as to punish severely half a dozen men who refused to comply with the order; but one Ohio colonel assumed to know more on the subject of vaccination than his surgeon, and refused to issue an order requiring the operation, saying that he did not believe in vaccination. When this regiment reached the South, however, the dictum of the colonel was overruled by higher authority, and the three medical officers were compelled to vaccinate their eleven hundred men under the added disadvantages of the crowded tent life, in the heat and dust of the southern camp, and during the work and constant drills which were necessary there; consequently the cleanliness, asepsis, and the rest for the affected arms which was desirable, could not be obtained, and infected arms were very numerous, thus throwing much unnecessary additional work upon the surgeons, delaying the efficiency of the regiment, and, I doubt not, laying the foundations for numerous pension claims. Many such instances might be narrated of arbitrary overruling of medical recommendations with unfortunate results, but time does not permit. Medical officers protested against the location of certain camps and the continued occupation of the same site for lengthened periods, calling attention to the fact that all authorities fix the limit of safety for continuous occupation at two weeks, but their protests and recommendations were frequently endorsed, "not concurred in," and the world knows the results that followed at Chickamauga, Tampa, Tampa Heights, and elsewhere. Colonel J. D. Griffiths, Chief Surgeon 3d Division First Army Corps at Chickamauga, says, "Our Medical Department should be divorced from the Quartermaster's Department. As a matter of fact the Quartermaster's Department is largely at fault for much of the trouble, and, while satisfactory for a small army in time of peace, when built upon and expanded as required for an army ten times as large, it failed absolutely and went to pieces. During the hot summer months 75 per cent. of the command still wore the heavy woolen clothing. Insufficient tentage was issued, resulting in overcrowding and this was a cause of much of the subsequent sickness." To these remarks I would add that during the first few weeks it was impossible to secure lumber for tent floors, such requisitions being always disapproved, and as for the tent crowding it was frightful at all times. Many of our men were still in the little shelter tents, well named "pup-tents" by them, all through the rainy season at Port Tampa City. Not until August could tent floors be obtained by our regiment. Requests for disinfectants were met by harsh instructions to read the Regulations, which provide as follows: "The routine use of disinfectants is prohibited." Later when public indignation was aroused against the conditions prevailing, all these supplies were issued freely; but at that time it was like locking the stable door after the horse had been stolen. When at Columbus and still under state control, a liberal supply of chlorid of lime was supplied and used in the sinks; but as soon as we were mustered into the service of the United States, this stopped instantly, because, under the Army Regulations, we were required to cover the contents of the sinks three times daily with dry earth, notwithstanding the fact that at that time it was raining every day, the camp was a sea of mud most of the time, and the sinks half full of water. Surgeon-General Sternberg himself, in his Presidential Address before the Association of Military Surgeons of the United States, in 1895, after commenting upon the mortality during the Civil war, predicted that the sickness and mortality from typhoid fever, dysentery and traumatic infectious diseases would be much less in any future war, but made an important qualification of his prediction as follows: "The extent to which this may be accomplished will depend upon the preparations we make in advance and upon the success we have in obtaining the intelligent cooperation of officers in command of troops in carrying out the recommendations we may make."

On the subject of control of all property and transportation, the defects in the present system are most conspicuous, and Major Owen is undoubtedly right when he calls attention to the complications that might arise under the provisions of the Geneva Convention. The distinction between the European and the American meaning of the word "ambulance" must be carefully borne in mind. In our country it means simply the ambulance wagon, whilst abroad it means the entire field hospital. In our army, under the present system, nothing is exempt from capture except the ambulance wagons, the sick men and their medicines, in addition to the surgeons, hospital corps and nurses. The enemy may legally take the tents over their heads, the cots on which they lie, their food and clothing, their cooking outfit, their wagons, horses, mules, and practically all the hospital supplies, except the medicines and ambulance wagons. And all this simply because tentage, cots, wagons, etc., belong to the Quartermaster's Department and nothing of the Quartermaster's property comes under the provisions of the Geneva Convention. The Hospital Department occupies a position of dependency upon the Quartermaster's Department for absolute necessities. Ordinarily these are supplied freely, but just when they will be most urgently needed, then the Quartermaster will be unable to supply them, and there lies the fatal error of the situation. Just at the time when the surgeon may be asking the Quartermaster to give him more tentage, wagons and mules, the Quartermaster, in the exigencies of the occasion, may feel it necessary for the public service to take away what he has already given. If ammunition and other supplies are needed at the front, the Quartermaster will certainly keep his wagons for that purpose or hold the tents to keep supplies in, rather than issue them to the Hospital Department. The preservation of the fighting line will be considered as of more importance than the comfort of the sick. Over in the Philippines the captain of a company marching all day in the rain reprimanded his men when he found they were covering their shoulders with the flannel cloth given them to cover their rifle locks, saying, "keep your rifles dry, the government can get plenty more men in your places, but it can not get Krag rifles in the place of those you spoil here." How many times has it occurred that when the surgeon asked for wagons to haul ice or water for the hospital, he was told by the Quartermaster that all the wagons were engaged in hauling wood! General Sternberg had his supplies ready at Tampa, but under the Regulations he had to depend upon another department for their transportation to Cuba and that transportation he could not get. If General Sternberg had possessed his own means of transportation for his department Clara Barton could not have made the observation she did. Under present conditions if we go to war again, the sad experiences of the Civil war and of the Spanish-American war, the needless suffering and want endured by the sick and wounded, will be repeated and we will have to depend on outside volunteer relief organizations to do the work that the regular Medical Department could and would do if their hands were not tied.

The system is faulty, therefore the results must be bad. It will never do to depend on volunteer civil organizations to do permanent work in a military campaign. The Sanitary Commission did noble work during the Civil war, but that was a generation ago before our knowledge was in any degree perfected. The National Red Cross helped very much during the Spanish-American war, but their aid should have been unnecessary. Their hospital ship was the first vessel to sail into Santiago harbor and its cargo was a literal godsend to the people there. During the Franco-Prussian war the French Red Cross Society undertook to care for the sick and wounded of the army and established numerous ambulances as field hospitals, but those in charge were compelled to admit the system was incorrect. One says: "The sanitary service of the army should have an organization wholly military and in no way civil, especially on the battlefield;" another says, "There can be no place in any well-regulated army for a volunteer health service." If my information is correct, France has recently made the Medical Department of her army an independent, autonomous department well organized for effective service. Our Medical Department should be so complete that outside interference, well meant as assistance, but nevertheless an intermeddling which causes confusion, will not be necessary and therefore will not present itself. Dr. Tripler, in commenting on some of the difficulties arising during the Civil war, says: "Certain persons suddenly smitten with a more intricate knowledge and thorough perception of the duties and administration of the Medical Department than I had been able to acquire in thirty years of experience and study, obtruded their crude suggestions, marring where they could not make, and paralyzing where they attempted to quicken, succeeded by their uninformed zeal. They, innocently enough, perhaps, but none the less unfortunately enough, succeeded in defeating the measures I had much at heart, had carefully contemplated and intended to carry into effect at the proper time." Not only is this outside interference often irritating, troublesome and non-effective for real good, but it certainly is humiliating for a great nation to be obliged to depend on aid societies and charitable persons for ice and other necessary medical supplies. There will always be ample room for the charitable organizations to do good work in the large base hospitals and among the sick and wounded sent to their homes, but in the field hospitals and in the regimental dispensaries the Medical Department should have the exclusive management of affairs.

By the establishment of the Army Medical School and the Naval Medical School, facilities were provided for the complete training of medical officers for their special work; thus by the creation and excellent development of the Hospital Corps, the Medical Department secured a permanent body of trained, intelligent helpers under its exclusive control, and finally, by the adoption of the trained female nurse system, it perfected and completed its facilities to care for the sick so far as the personnel of the working force was concerned. If now the defects pointed out by Major Owen can be remedied, we shall have a Medical Department which will be a model for the nations of the world.

Now just a few words upon the relation of this subject to the National Guard and the State Medical Department. The nation must, of course, depend upon the National Guard to swell the army to effective strength in time of war and will always be the training school of popular military knowledge. In order that the transfer from state to federal control may take place promptly and easily, the National Guard in its organization, equipment, discipline and instruction must be identical, as near as possible, with the regular establishment. The physical examination of recruits must be thorough and rigid, based closely upon the rules laid down in Tripler's Manual. The Medical Department must be removed from the influence of politics or personal favoritism, and detached from local regimental control. That is, medical officers must be members of the state medical department instead of mere regimental staff officers. They must be appointed only after rigid technical examinations before a board of medical officers, re-examined after three years' service for promotion to captaincy, then again examined at the end of five years for promotion to surgeon-major, provided a vacancy exists. The hospital corps likewise should be enlisted as members of a state hospital corps under exclusive control of the Medical Department. The hospital stewards should begin as acting stewards and secure promotion by examination after one year, the same as in the army. The matter of detailing surgeons, assistant surgeons, stewards, and hospital corps men to serve with the various regiments should be very simple. The above plan is in operation in the states of Minnesota, New Jersey and Massachusetts, so far as state laws permit, and it is found to work in a satisfactory manner. What is urgently needed is uniformity in all the states, and this can only be secured by enactment at Washington of laws that will make the National Guard a secondary or reserve part of the army, thus insuring thorough military control and thorough inspections with power to weed out triflers and incompetents and to build up an effective organization that will stand ready to march at short notice from the local armories direct to the field of operation.

But coming back to the Medical Department: with the organization I have suggested and the use in that organization of all blanks, forms, reports, requisitions, etc., precisely as used in the army Medical Department, substituting only the name of the state in place of that of the United States, and with medical supplies of the same nature, obtained and expended under the same regulations, the terrible bugbear of "paper work" will not be a burden and "red-tape" will not be complained of when the guard is suddenly called to active duty, because the forms will be familiar and the great benefits of the much-dreaded red-tape will be known and appreciated. With medical officers and stewards thus made familiar with the forms of paper-work and the details of Regulations, the Volunteer Medical Officers will be ready to at once work hand in hand with their brethren of the regular service and would cease to merit the title of "fool volunteer."

Dr. Charles H. Castle (Late Captain and Assistant Surgeon First Ohio Volunteer Cavalry, Spanish-American war) said: An experience of some seven months with our army hospitals in the field leads me to unqualifiedly endorse Major Owen's demand that the Medical Department shall be taken from its present absurd and disgraceful dependence upon other departments for its supplies and transportation. There is a publication issued by the government called the United States Army Regulations, and during my first two months in the service I studied this assiduously, but notwithstanding the study I do not think that the full hideousness of its absurdity struck me until one day the ordinance officer, mind you, the man who deals in ponderous death-dealing weapons—in shot and shell and tons of smokeless powder, and in seige trains miles long—came around and gave me a knife and fork and spoon and made me receipt for them!

Major Owen refers in particular to the conditions in the large camp at Chickamauga. Thanks to the liberality of the State of Ohio and some personal friends of the regiment, and thanks also to the fact that we were camped on a sunny plain with good natural drainage, the First Ohio Volunteer Cavalry to which I was attached was almost independent of the government it was serving, in the matter of medical and surgical supplies; as late as the month of June, three months after the regular forces had established themselves in this camp, our regimental hospital had to lend to the headquarters hospital of the Commanding Major-General, mentioned in Major Owen's paper, the necessary surgical dressings for an operation for extirpation of the inguinal glands! The only possible way of accounting for this dearth was that the Medical Department had to depend upon the Quartermaster's Department for transportation, and that department had its mind and its box-cars filled with uniforms, and boots and shoes and tents. Speaking of tents allows me to record the manner in which the Medical Department of the United States Army sometimes gets tents for its typhoid fever patients—and sometimes does not. You will perhaps pardon me for quoting from the medical history of the First Ohio Cavalry which I had the honor to read before you some two years ago. During the first ten days at Camp George H. Thomas, the medical officers of the regiment had two difficulties to contend with; one was the delay in furnishing the troops with fresh beef, keeping them on the travel ration known among the soldiers as "canned giraffe" because it seemed to be all neck, until their hitherto untried digestions were thoroughly upset; and the second was the difficulty in procuring hospital tents. The two medical officers were each entitled to a wall tent, but for the sake of the sick we were obliged to bunk together and give up one of our 8x10 tents as a hospital. Repeated requisitions made by Major Bunts failed of response, until one of our majors of the line, an ex-officer of the regular artillery, discovered that he had in the chief quartermaster an old friend, and his personal solicitation accomplished promptly what a requisition "through the regular military channels" was powerless to effect. Two hospital tents were therefore given to us, and never, from that time, the last week in May, until the 20th of September, when I turned them over to the Depot Quartermaster at Tampa, failed to leak whenever it chanced to rain. These tents were inspected at least once at Chickamauga, and condemned, but were never replaced.

The regiment had left Chickamauga just as the violent epidemic of typhoid had begun there, and had proceeded as ordered, to Lakeland, Fla. For the ten days following our arrival at Lakeland we received our daily addition of cases of typhoid, all cases dating back to Chickamauga, and the additions ceasing as we reached the limits for the period of incubation. Thus on the 18th we received 2, on the 19th 2, on the 20th 2, on the 22d 3, on the 23d 2, on the 24th 1, on the 25th 2, and on the 26th 2. By July 22 we had 12 in the hospital, just filling it; by the 23d we had 14 in hospital, overfilling it. The hospital was cleared of all cases but typhoid, for we knew of typhoids in quarters that needed attention. Requisitions were made on the Quartermaster's Depot at Tampa, and after a delay of a week, we received one more tent. So that on July 27, when, we may say, we harvested the entire crop of the Chickamauga epidemic that we had brought with us, we had 18 in hospital, filling it, and 34 in quarters, 12 of which latter were typhoid. Being in quarters means lying on the sand floor of a tent, with one blanket under you, and one blanket over you, not at all a bad bed in summertime; but it also means getting up and going to the cook tent every time you want a drink of water, and walking one or two hundred yards outside the confines of camp every time you have one of those frequent typhoid stools, and it became my melancholy duty to make a postmortem examination of a private in the First United States Cavalry—our neighbors—who died of exhaustion from this cause. Early one hot, damp morning this patient walked from his quarters to the sink and back again, laid down, and died an absolutely unnecessary death. The postmortem showed the characteristic lesions of typhoid fever in the second week occurring in a man previously suffering from marked inanition.

About this time there came to us, on behalf of the Army and Navy League of Cincinnati, a lady of education, refinement and tact, and one absolutely devoid of the hysteria that unfortunately afflicted so many of the ordinary camp visitors; she was full of sound common sense that she had gathered in sojournings in various parts of the world. This personal inspection on the part of the Army and Navy League made it the most valuable agency of the kind that I know of, not excepting the Red Cross Society. The camps of the brigade were inspected and the situation discussed, and the need of tents, cots, hospital furnishings, milk, eggs, etc., were acknowledged. Hospital tents had been requisitioned for by Major Bunts, but could not be had, as the Quartermaster at Tampa asserted that all available tents had been given to the new West Tampa [illegible] Hospital and to the depots at Fernandina; cots could [illegible]ad presumably for the same reason, and the limited [illegible] of cots in the village of Lakeland had been exhausted; [illegible]and eggs were being bought by the money supplied by [illegible]eland friends of the regiment. This business-like angel [illegible] the Army and Navy League went to Tampa, obtained an interview with the Quartermaster, and a promise of the necessary tents—the second time in our short military history where an unofficial interview of an outsider accomplished promptly what the requisition "through regular military channels" had totally failed to do. I met the lady the next day in Tampa. We went together to the Quartermaster's office. I stated my errand to the assistant temporarily in charge—the procuring of hospital tents. He politely refused my request on the grounds that he had none. I represented the urgency of the case, the large number of our sick, and the character of their illness. Still a refusal. Then the lady interposed; she announced the promise made by his chief the day before, and the gallant assistant went to the telephone, called up the Quartermaster's Depot, asked how many hospital tents they had, and directed that four be sent at once to the First Ohio Cavalry at Lakewood.

Having seen, now, how the Quartermaster's Department aids the medical officer in his daily visits to the sick, let us see how another department discharged its duties toward the dependent Medical Department. The methods of feeding the sick in the hospitals of the armies of the United States are practically as follows: When a soldier is sick or wounded and is transfered to a hospital, the Commissary Department subtracts his rations from the total amount going to his company, troop or battery and is supposed to send the ration to the hospital in which the soldier lies; and as even the United States Government knows that sick men frequently need dissimilar food from well men, provision is made that at the request of the surgeon in charge, the Commissary Department shall buy this ration from the hospital, or, in other words, shall furnish money at the rate approximately of seventeen or eighteen cents a meal, so that sowbelly, onions, hard tack, and coffee can give way to milk and eggs. Notwithstanding this express provision of the Army Regulations, the Chief Quartermaster at Camp Thomas, Chickamauga Park, Ga., flatly refused to purchase these savings made by our hospital, though frequently requested to do so by Surgeon-Major Bunts through our regimental commissary. I do not know his excuse. The better his excuse the more is exhibited the inherent viciousness of this detestable system. Our sick men were fed milk and eggs by the women of Chattanooga, and every morning our ambulance could be seen along with a long line of other medical mendicants outside the door of their commissary depot, where they were performing the functions abandoned by the men of the War Department of the United States. That this most peculiar and roundabout method of supplying hospitals with food has its disadvantages, to say the least, was illustrated again in our hospital at Lakeland, Fla., when the Second Provisional Cavalry Brigade of the Fourth Army Corps moved north and left me under the pines of Florida with seventy sick men in bed. The brigade commissary did all he could for me; he directed the commissary officer to leave rations with me for thirty days for the whole number of sick. These hideous things could not be eaten by typhoid fever patients and must be sold to purchase milk; but every commissary sergeant in the brigade had been trading sowbelly, coffee, flour and baking powder to the neighboring "crackers" for fresh vegetables for six weeks past, and when I came to sell I found the market overstocked and prices ruinously low. During our mad quest for purchasers almost all of our perishable articles, like potatoes, onions, hard-tack, etc., spoiled, for they had no shelter, so that our total realization from these rations was not enough to keep our hospital going one week. It is true that an order was promulgated from the Adjutant-General's office on Aug. 15, 1898, allowing to the hospitals from the funds of the Commissary Department, sixty cents a day per patient. As soon as I discovered this I made application for the allowance. In the interval before its receipt, Dr. Partello, the resident agent of the Red Cross Society at Tampa, visited me and when I told him that I had made application for the sixty cents per day, he deplored the fact, told me that I had better not accept it when it came, and that it would be an almost endless source of annoyance and confusion to me. I regret to be compelled to state that the predictions of the good Doctor have been fully verified. They compelled me to pay back out of the sixty cents the full value of all the rations that had spoiled or been sold at nominal prices, so that really the net result of my application was abundant correspondence, voluminous reports, severe aggravation of the surgeon, and unabated, unappeased hunger of the typhoid convalescents. The regular medical officer in charge of the West Tampa [illegible]l, having had seven years' experience of Depa[illegible] exhibited a degree of skill and tact in his [illegible] this matter worthy of all admiration. He [illegible]r diem for his patient and lodged it [illegible] that he could say [illegible] ny i [illegible] ing ne [illegible] p visitor: "[illegible] as he con- t[illegible] an[illegible] Red Cross [illegible]es, his [illegible]ment. [illegible]ied [illegible] he [illegible] r-latter point it is often too late to prevent harm being done. I have frequently had to condemn food in a troop kitchen right under the eyes of hungry soldiers, who, I was sure, felt no gratitude whatever as the poisons were removed, as there was practically very little else that was palatable left to eat. Digestive disorders, then, as we see, sometimes deprive a commanding officer of one-half of the men sent to him by his government as fighting men. Improper food is in nine cases out of ten the cause of digestive disturbances. Should no one else approve, the commanding general should be grateful if the medical man should step in and by a proper supervision of the food supply, keep to the fighting line at least ten, twenty, or thirty more men in every hundred. It is not difficult to fix the status of the beef that was issued as a factor in this indigestion. We never saw any of the canned roast beef that has produced such a controversy. None was ever issued to the regiment at Chickamauga, and at Lakeland our Commissary heard so many complaints of it from the regulars who were our neighbors, that he refused to touch it and always demanded as the meat of his travel ration the canned corn beef or "canned giraffe." As for the refrigerated beef, it was very difficult to keep, and decomposition with the formation of ptomaines sometimes took place in an hour or so; I have condemned in a cook tent at noon, beef that had passed inspection at 10:30 or 11 a. m. I condemned several tons of this refrigerated beef at Lakeland.

The soldier of the republic must not be regarded only in the light as of food for powder. He is not a conscript, but voluntarily puts on a uniform which he has a right to expect will secure to him all the efficiency possible in fighting his country's enemies, and when that duty is over, if unwounded, he should return to his productive activities a healthy man. Suggestions for specific remedies must come from the experts; the medical officers of the regular service are the only ones who are well enough acquainted with the conditions both as they exist and as they should be, to be able to formulate proper plans. We know now that in at least one of our wars, the Spanish-American war, the medical officer had more work to do, and, considering his shamefully inadequate means, did it better than any other officer in the service, not even excepting the innumerable heroes of San Juan Hill. And one other thing: we know that the war against the Spaniard was a puny, miserable affair in comparison with our war against typhoid; for in this latter, those who should have been our allies aided the enemy. There are perhaps two other considerations that should claim our attention, though they may not bear directly upon Major Owen's contention. The first is that while the army Medical Department should be absolutely relieved from its present crippling dependence upon an overburdened Quartermaster's Department and from the Commissary Department, it should at the same time set its own officers free from a childish dependence upon their chief at Washington.

Finally, the strength of a chain is only the strength of its weakest link, and one of the links of the chain we are considering is the private soldier. The private soldier is usually a very verdant individual and in the calf stage of existence. He will go without camp bounds and drink of forbidden water and eat of forbidden and monstrous thinks sold by hucksters, and now that the canteen is abolished, he will get out of the garrison and drink of vile and forbidden whiskey. The private soldier does not know, and I have never heard that any provision has been made to instruct him, until after he gets sick, when his surgeon has the opportunity to give him some bedside instructions. When I was in service, the commanding officer of our regiment requested the medical officers to deliver occasional lectures at the daily Officers' and Non-Commissioned Officers' School, and I do not know of even this being done in any of the organizations camped in our neighborhood. These instructions should be extended to all and should be held to be an extremely important part of the schooling of the soldier, especially when we know that in all armies in all times, more men have perished from disease than from wounds. In fact, the saying of the old prophet that "they who take the sword shall perish by the sword" never has been correct; and the proper rendering of that biblical verse should be "they who take the sword shall perish by diarrhea." This is true, but it is not creditable to the American people and the twentieth century, and it probably can be stopped, but only in the way which Major Owen's paper indicates.

Dr. W. O. Owen (Major and Surgeon, United States Army) in closing the discussion, said: That which I tell you is no new story, for Irving C. Rosse said some years ago, "If the army medical officer were so fully aware of the importance of prevailing disease and the efficacy of judicious sanitary measures in their prevention, how does it happen that a state of affairs so completely opposed to the first principles of hygiene has been permitted to exist? An answer to this question is found in the unsettled relations existing between the military and medical authorities. In former days the military authorities held that the duties of a medical officer were to treat the sick and wounded, and any recommendations bearing on the general management of the men were deemed intrusive and resented as an interference with the province of the commanding officer. 'Medical opinions are very good when called for' was said to the senior medical officer in the Burmese war; and in the Crimean war, Inspector-General Alexander was informed by a general of division that he 'had better keep his suggestions and strictures until asked for.' It was not within the power of the medical officer, as at the present day, to remedy such evils, and if the suggestions were acted upon at all, it was owing to the common sense or the good feeling of the Commanding Officer."

The above is a very bitter statement of a truth existing in the past. That such a condition can exist may to-day be questioned. Yet a friend of mine, a gentleman who was born in the city of Cincinnati and is a friend of many present, informed me that in 1898 he reported to the general in command of the camp in which he was on duty that the camp was in bad condition and that an epidemic of typhoid was threatening. The answer that he received was an order to leave the general's tent and not to return to it unless he was sent for. How well the medical officer was listened to in the Crimean war is shown by the fact that many regiments lost over 10 per cent. of their strength, some 45 per cent., some 75 per cent., and one lost more than its average strength. It was in this war that the inspector-general was told that he "had better keep his suggestions and strictures until called for." It was in this same war that 20,000 pounds of lime juice were held for future use while scurvy was disabling the entire force.

It is not my idea to attack any man for the past, but to tell of the past that we may be enabled to see more clearly what is needed in order that we may be able to so draw a law that the responsibility may be fixed definitely on some one man, so that he may suffer for his carelessness, or that he may be removed for his lack of ability to control matters which he has been appointed to superintend. Have a law so drawn that it fixes definitely the responsibility. The bill I offer will do this, for the sixth paragraph puts in the hands of the Secretary of War to say when and under what conditions the line can take away from the Medical Department the responsibilities placed upon them by this bill. I have offered this only as a thought in the right direction; if any one will better it, I shall be grateful. My belief is that the line should at all times have the right to take upon their shoulders an absolute disregard for all sanitary law, but that when they do, that they should do so with a direct personal responsibility under the law for the accuracy of judgment used as shown by the results attained. I can not think that men should be subjected to unsanitary conditions in camps of assembly, in camps of instruction, or in war time when the approach of the enemy is not to be dreaded. Sanitary dangers like all other dangers must be taken, when in the opinion of the man in command it is necessary to do so for the general good.

I desire to call attention to General Orders 100, 1863, the last part of 116 says, "An honorable belligerent allows himself to be guided by flags or signals of protection as much as the contingencies and the necessities of the fight will permit.

for we knew of typhoids in quarters that needed attention. Requisitions were made on the Quartermaster's Depot at Tampa, and after a delay of a week, we received one more tent. So that on July 27, when, we may say, we harvested the entire crop of the Chickamauga epidemic that we had brought with us, we had 18 in hospital, filling it, and 34 in quarters, 12 of which latter were typhoid. Being in quarters means lying on the sand floor of a tent, with one blanket under you, and one blanket over you, not at all a bad bed in summertime; but it also means getting up and going to the cook tent every time you want a drink of water, and walking one or two hundred yards outside the confines of camp every time you have one of those frequent typhoid stools, and it became my melancholy duty to make a postmortem examination of a private in the First United States Cavalry—our neighbors—who died of exhaustion from this cause. Early one hot, damp morning this patient walked from his quarters to the sink and back again, laid down, and died an absolutely unnecessary death. The postmortem showed the characteristic lesions of typhoid fever in the second week occurring in a man previously suffering from marked inanition.

About this time there came to us, on behalf of the Army and Navy League of Cincinnati, a lady of education, refinement and tact, and one absolutely devoid of the hysteria that unfortunately afflicted so many of the ordinary camp visitors; she was full of sound common sense that she had gathered in sojournings in various parts of the world. This personal inspection on the part of the Army and Navy League made it the most valuable agency of the kind that I know of, not excepting the Red Cross Society. The camps of the brigade were inspected and the situation discussed, and the need of tents, cots, hospital furnishings, milk, eggs, etc., were acknowledged. Hospital tents had been requisitioned for by Major Bunts, but could not be had, as the Quartermaster at Tampa asserted that all available tents had been given to the new West Tampa Fever Hospital and to the depots at Fernandina; cots could not be had presumably for the same reason, and the limited supply of cots in the village of Lakeland had been exhausted; milk and eggs were being bought by the money supplied by Cleveland friends of the regiment. This business-like angel of the Army and Navy League went to Tampa, obtained an interview with the Quartermaster, and a promise of the necessary tents—the second time in our short military history where an unofficial interview of an outsider accomplished promptly what the requisition "through regular military channels" had totally failed to do. I met the lady the next day in Tampa. We went together to the Quartermaster's office. I stated my errand to the assistant temporarily in charge—the procuring of hospital tents. It is true that an order was promulgated from the Adjutant-General's office on Aug. 15, 1898, allowing to the hospitals from the funds of the Commissary Department, sixty cents a day per patient. As soon as I discovered this I made application for the allowance. In the interval before its receipt, Dr. Partello, the resident agent of the Red Cross Society at Tampa, visited me and when I told him that I had made application for the sixty cents per day, he deplored the fact, told me that I had better not accept it when it came, and that it would be an almost endless source of annoyance and confusion to me. I regret to be compelled to state that the predictions of the good Doctor have been fully verified. They compelled me to pay back out of the sixty cents the full value of all the rations that had spoiled or been sold at nominal prices, so that really the net result of my application was abundant correspondence, voluminous reports, severe aggravation of the surgeon, and unabated, unappeased hunger of the typhoid convalescents. The regular medical officer in charge of the West Tampa Fever Hospital, having had seven years' experience of Departmental methods, exhibited a degree of skill and tact in his managment of this matter worthy of all admiration. He drew his sixty cents per diem for his patient and lodged it safely in the bank, so that he could say to any inquiring newspaper man or anxious camp visitor: "See, I am abundantly supplied with funds," but as he continued courteously and gratefully to allow the Red Cross Society to purchase all his food and other necessities, his final reports consisted merely in handing the Government money back again practically untouched; and he had gratified the charitable contributors to the Red Cross fund in the knowledge that it was their ministrations that kept his mortality down to 5 per cent.!

The first disease that enters a military camp is diarrhea; in the midst of a campaign, whether the business in hand be fighting, or seige, or only garrison duty, the diarrheal diseases absorb by far the greatest number of "sick and wounded." The story is the same whether the campaign be a tropical one like ours in Cuba, or amidst the ice and snows that confronted the allied armies of the Crimea. Macleod says of the terrible winter of 1854-1855, that the percentage of sick in eight army corps was 73 per cent., and on another page his figures show that 66 per cent. of the sick had typhoid fever. It is then but reasonable to demand that the medical officer, the sanitarium, should designate what food should be furnished to troops, and that he should have a chance to inspect this food before it reaches the hands of the regimental commissary. At this latter point it is often too late to prevent harm being done. I have frequently had to condemn food in a troop kitchen right under the eyes of hungry soldiers, who, I was sure, felt no gratitude whatever as the poisons were removed, as there was practically very little else that was palatable left to eat. Digestive disorders, then, as we see, sometimes deprive a commanding officer of one-half of the men sent to him by his government as fighting men. Improper food is in nine cases out of ten the cause of digestive disturbances. Should no one else approve, the commanding general should be grateful if the medical man should step in and by a proper supervision of the food supply, keep to the fighting line at least ten, twenty, or thirty more men in every hundred. It is not difficult to fix the status of the beef that was issued as a factor in this indigestion. We never saw any of the canned roast beef that has produced such a controversy. None was ever issued to the regiment at Chickamauga, and at Lakeland our Commissary heard so many complaints of it from the regulars who were our neighbors, that he refused to touch it and always demanded as the meat of his travel ration the canned corn beef or "canned giraffe." As for the refrigerated beef, it was very difficult to keep, and decomposition with the formation of ptomaines sometimes took place in an hour or so; I have condemned in a cook tent at noon, beef that had passed inspection at 10:30 or 11 a. m. I condemned several tons of this refrigerated beef at Lakeland.

The soldier of the republic must not be regarded only in the light as of food for powder. He is not a conscript, but voluntarily puts on a uniform which he has a right to expect will secure to him all the efficiency possible in fighting his country's enemies, and when that duty is over, if unwounded, he should return to his productive activities a healthy man. Suggestions for specific remedies must come from the experts; the medical officers of the regular service are the only ones who are well enough acquainted with the conditions both as they exist and as they should be, to be able to formulate proper plans. We know now that in at least one of our wars, the Spanish-American war, the medical officer had more work to do, and, considering his shamefully inadequate means, did it better than any other officer in the service, not even excepting the innumerable heroes of San Juan Hill. And one other thing: we know that the war against the Spaniard was a puny, miserable affair in comparison with our war against typhoid; for in this latter, those who should have been our allies aided the enemy. There are perhaps two other considerations that should claim our attention, though they may not bear directly upon Major Owen's contention. The first is that while the army Medical Department should be absolutely relieved from its present crippling dependence upon an overburdened Quartermaster's Department and from the Commissary Department, it should at the same time set its own officers free from a childish dependence upon their chief at Washington.

Finally, the strength of a chain is only the strength of its weakest link, and one of the links of the chain we are considering is the private soldier. The private soldier is usually a very verdant individual and in the calf stage of existence. He will go without camp bounds and drink of forbidden water and eat of forbidden and monstrous thinks sold by hucksters, and now that the canteen is abolished, he will get out of the garrison and drink of vile and forbidden whiskey. The private soldier does not know, and I have never heard that any provision has been made to instruct him, until after he gets sick, when his surgeon has the opportunity to give him some bedside instructions. When I was in service, the commanding officer of our regiment requested the medical officers to deliver occasional lectures at the daily Officers' and Non-Commissioned Officers' School, and I do not know of even this being done in any of the organizations camped in our neighborhood. These instructions should be extended to all and should be held to be an extremely important part of the schooling of the soldier, especially when we know that in all armies in all times, more men have perished from disease than from wounds. In fact, the saying of the old prophet that "they who take the sword shall perish by the sword" never has been correct; and the proper rendering of that biblical verse should be "they who take the sword shall perish by diarrhea." This is true, but it is not creditable to the American people and the twentieth century, and it probably can be stopped, but only in the way which Major Owen's paper indicates.

Dr. W. O. Owen (Major and Surgeon, United States Army) in closing the discussion, said: That which I tell you is no new story, for Irving C. Rosse said some years ago, "If the army medical officer were so fully aware of the importance of prevailing disease and the efficacy of judicious sanitary measures in their prevention, how does it happen that a state of affairs so completely opposed to the first principles of hygiene has been permitted to exist? An answer to this question is found in the unsettled relations existing between the military and medical authorities. In former days the military authorities held that the duties of a medical officer were to treat the sick and wounded, and any recommendations bearing on the general management of the men were deemed intrusive and resented as an interference with the province of the commanding officer. 'Medical opinions are very good when called for' was said to the senior medical officer in the Burmese war; and in the Crimean war, Inspector-General Alexander was informed by a general of division that he 'had better keep his suggestions and strictures until asked for.' It was not within the power of the medical officer, as at the present day, to remedy such evils, and if the suggestions were acted upon at all, it was owing to the common sense or the good feeling of the Commanding Officer."

The above is a very bitter statement of a truth existing in the past. That such a condition can exist may to-day be questioned. Yet a friend of mine, a gentleman who was born in the city of Cincinnati and is a friend of many present, informed me that in 1898 he reported to the general in command of the camp in which he was on duty that the camp was in bad condition and that an epidemic of typhoid was threatening. The answer that he received was an order to leave the general's tent and not to return to it unless he was sent for. How well the medical officer was listened to in the Crimean war is shown by the fact that many regiments lost over 10 per cent. of their strength, some 45 per cent., some 75 per cent., and one lost more than its average strength. It was in this war that the inspector-general was told that he "had better keep his suggestions and strictures until called for." It was in this same war that 20,000 pounds of lime juice were held for future use while scurvy was disabling the entire force.

It is not my idea to attack any man for the past, but to tell of the past that we may be enabled to see more clearly what is needed in order that we may be able to so draw a law that the responsibility may be fixed definitely on some one man, so that he may suffer for his carelessness, or that he may be removed for his lack of ability to control matters which he has been appointed to superintend. Have a law so drawn that it fixes definitely the responsibility. The bill I offer will do this, for the sixth paragraph puts in the hands of the Secretary of War to say when and under what conditions the line can take away from the Medical Department the responsibilities placed upon them by this bill. I have offered this only as a thought in the right direction; if any one will better it, I shall be grateful. My belief is that the line should at all times have the right to take upon their shoulders an absolute disregard for all sanitary law, but that when they do, that they should do so with a direct personal responsibility under the law for the accuracy of judgment used as shown by the results attained. I can not think that men should be subjected to unsanitary conditions in camps of assembly, in camps of instruction, or in war time when the approach of the enemy is not to be dreaded. Sanitary dangers like all other dangers must be taken, when in the opinion of the man in command it is necessary to do so for the general good.

I desire to call attention to General Orders 100, 1863, the last part of 116 says, "An honorable belligerent allows himself to be guided by flags or signals of protection as much as the contingencies and the necessities of the fight will permit.

117: It is justly considered an act of bad faith, or infamy or fiendishness, to deceive the enemy by flags of protection. Such act of bad faith may be good cause for refusing to respect such flags." The above was taken from the Army Regulations published the year before the United States became a party to the Geneva Convention. Yet, with a feeling of this sort published to the world, the hospitals do not have their own transportation. The United States, in the face of the Geneva Convention, still supplies the Medical Department with Quartermaster's transportation, tentage, etc., all because of the mistranslation of the French word "ambulance." The French regulation designates what constitutes an ambulance, giving the allowance of men, wagons, etc., which each class of ambulance shall have. Thus it is that the medical officer flying the Red Cross flag of the Geneva deceives the enemy, for the enemy does not know that all of these tents, wagons, horses, etc., which go to form an ambulance in the United States Army belong to the fighting force and that the fighting force is obligated, when their needs require, to take this material from the ambulances for their own use. They have the right to compel the Medical Department to again receive this property and again protect it from capture by flying over it the Red Cross flag of the Geneva Convention, when their necessity has passed. And hence it is that I have said that the Red Cross flag is a menace to the medical officer flying it over Quartermaster's property, which constitutes so large and important part of the ambulance or flying hospital of the United States Army.

So often has the thought been repeated to me that I am advocating a double-headed command, that I again feel called upon to state that I have insisted and still insist that the command continue to rest in the line where it belongs. I do, however, advocate that the Medical Department shall be made responsible for the sanitary condition of the army, and that penalties be attached for failure to avoid unsanitary conditions; that the right shall rest at all times in the line of the army to take this responsibility from the shoulders of the Medical Department to their own, taking with the responsibilities the penalties provided; that a full justification for their action shall always be the presence of the enemy and the dictation of military necessity.

Dr. J. C. Oliver moved that a copy of Mr. Hay's bill be sent to the Committee on National Regulation of the Ohio State Society with the endorsement of the Academy of Medicine of Cincinnati. Carried.

CALIFORNIA ACADEMY OF MEDICINE.

Regular Meeting, held at San Francisco, September 24.

Dr. D. W. Montgomery in the Chair.

Dr. Dudley Tait showed the necropsy specimens from a patient upon whom he had made a gastrostomy for cancer of the esophagus. The method employed (Poirier's operation) was briefly as follows: Incision through the rectus under local anesthesia; withdrawal of a cone of the muscular wall of the stomach and fixation of basis of the cone to the parietal peritoneum. A small opening is made at the summit of the cone, penetrating only the two outer layers of the stomach. This is easily done, for when the stomach wall is held between the thumb and index finger the mucous layer rolls away from the outer layer. The mucous layer is then pushed inwardly by blunt dissection, which is always bloodless. A small opening is made into the dome of mucous layer thus formed and a number fourteen or eighteen French catheter introduced. Stitching the edges of the outer cone to the skin, and closure of the remainder of the wall completes the operation, which seldom requires more than ten or fifteen minutes. The result in Dr. Tait's case was excellent; for eight months there was no leakage, and after that, leakage occurred only during intervals of gastric disturbances as manifested by hypersecretion and hyperacidity. The patient was able to take food—liquid and solid—by mouth shortly after the operation and continued doing so for four and a half months. Death from pulmonary congestion occurred thirteen months after the gastrostomy. The specimen showed the disappearance of everything resembling a canal. It is more than probable that this condition occurred early and that the continence was due to the folds of mucous membrane converging at the orifice in the stomach.

After having made seven gastrostomies by different methods, Dr. Tait gave preference to the valvular methods, among which he mentioned Fontan's and its modification by Poirier. Whatever be the method adopted the stomach opening must be very small, and in the majority of methods the tube should be introduced only at the time of feeding. Operation in two stages was dangerous as a long list of complications had demonstrated. Cocain anesthesia was a great improvement. Dr. Tait advised getting the patient up as early as the third day. Roux, of Lausanne, insisted strongly on this proposition in all of his cases of gastric surgery. The return of permeability of the esophagus after gastrostomy was due to the gradual disappearance of the fibro-stenotic process involving the tissues contiguous to the neoplasm. A similar condition was found in rectal growths after colostomy. Dr. Tait spoke briefly of experimental work he had done in view of permitting the patient to take food by the mouth in cases of stricture of the esophagus. The plan consisted in anastomosing the greater curvature of the stomach to a point on the esophagus situated above the stricture. He found that traction on the cardia invariably caused grave respiratory changes, although it was possible to dissect free and bring down a certain portion of the esophagus. Operation from behind was entirely unsuccessful.

Dr. Howard Morrow presented a man with a sarcoma on his forehead. The growth began two years ago, in the skin, at the root of his nose and was removed by a paste. Two months ago it reappeared and now extends within a half inch of the inner canthus of the left eye. The entire growth is in the subcutaneous tissue and only adherent to the skin at the point of the former scar. The patient was brought before the Academy to get the opinion of the members in regard to the best means of treatment.

Dr. H. M. Sherman said that he had never had to deal with a tumor of that character, in that location, but it did not seem to him that it would be difficult of removal as all the nodules were movable. It was possible that the growth was deeper than one would expect. He referred to the use of Coley's fluid in the treatment of such growths, and the recent publication of a paper by Coley, which cited a number of cases where satisfactory microscopic diagnoses were made, and under the use of the mixture the tumor disappeared. He thought we could not shrug our shoulders at a paper of that kind. Wyeth has stated that an incision could be made over the tumor and the tumor bathed in the fluid, but he thought it was best to remove these masses, and if some were found in front of the frontal sinus they still would be accessible for the use of Coley's fluid.

Dr. H. A. L. Ryfkogel said he had watched three cases where Coley's fluid had been used, but none of the cases were spindle-cell sarcomas. He thought it was advisable to use it for the prevention of recurrence.

Dr. Morrow also presented a man with a chancre on the tip of his tongue, of two months' duration. One week ago a typical roseola appeared on his chest. This patient was presented on account of the unusual position of the primary sore.

Dr. Dudley Tait showed photographs of a case of Dupuytren's contraction, in which all the fingers of both hands were involved. The palmar retraction was both longitudinal and transverse and on the plantar surfaces there existed a slight degree of contraction. The latter feature, noted in two former cases, was considered sufficient to eliminate traumatism as an etiologic factor. The difference of opinion in regard to treatment of this lesion could be explained in part by the existence of three distinct stages or forms of the pathologic condition; in the first, the most frequent, the aponeurosis only is involved; in the second, the skin also; in the third, the joints in addition to the aponeurosis and skin. Dr. Tait had talked recently with several European surgeons in reference to the treatment of Dupuytren's contraction, and found most of them advising radical excision, followed by grafts, in the advanced forms. Multiple subcutaneous incisions, as advised by Sir Astley Cooper and subsequently by Adams, demanded long and painful after-treatment and were frequently follcwed by recurrence. In the early stage, massage and constitutional treatment—for arthritism and diabetes—give excellent results in this lesion which belonged to the domain of medicine rather than to that f surgery.

Dr. G. Gross read a paper on "Intra-Muscular Mercurial njections in the Treatment of Syphilis." After going into the istory of this form of treatment, his paper took up the echnic of the injections. He preferred calomel to other merurial preparations, and used a glass syringe with a platinum-ridium needle 5 to 6 cm. long, which could be passed through he flame. The author claimed that the injections were not ainful in themselves, but by the third day, very often, more or ess severe pain and swelling was likely to develop. He hought that in order to pass judgment on this treatment, one ust give it a fair trial, with fair warning to patient, and the plendid results obtained would convert those who would perevere.

Dr. G. Caglieri, in discussing Dr. Gross's paper, stated that e did not think the author had shown any advantage in this ethod, and he thought there were decided objections to it; e thought the injection always produced some pain, and ometimes violent pain. Six weeks ago a man came to him uffering from marked syphilitic manifestations, who had just iven up treatment by another physician because he said he ould not stand the pain of these intra-muscular injections. ther methods of treatment he thought were equally as good nd not so painful. Of these the intra-venous injection method as probably the best. It was more soothing than the former nd not such rigid care was required. He described the technic f the injection and claimed that they were very easy of execuion. He used the 1 per cent. solution of cyanid of mercury n 20 m. doses daily for ten days, and then increased to a 2 per ent. solution, gradually lengthening the period between these njections until it is used once a week.

Dr. D. W. Montgomery said that he had but little experince with calomel injections, but that little had convinced him hat bichlorid injections were not so painful. He did not hink that unless the condition was ungovernable he would use alomel. He certainly would not use it in an ordinary case of yphilis, for one could get along very well with inunction or nternal treatment. He had never used the cyanid of merury.

Dr. Gross, in reply, said that he had made a number of ntra-venous injections and had always found them painful. ne advantage of the intra-muscular injection was that the ffect was more lasting. Regarding the pain he said he had sed the injections considerably and only remembered one case here the man did not come back. The method should be tried ithfully in order to prove its efficacy.

Therapeutics.

[It is the aim of this department to aid the general practiner by giving practical prescriptions and, in brief, methods treatment for the diseases seen especially in every-day prace. Proper inquiries concerning general formulae and outes of treatment will be answered in these columns.]

Treatment of Cough and Pain in Tuberculosis.

The following is recommended in *Amer. Med.*:

℞.	Aq. Aurantii flor.	℥iv	128	
	Syr. chloralis			
	Syr. morphinæ, āā	℥i	32	
	Aq. laurocerosi	ʒiii	12	

I. Sig.: One dessertspoonful every hour.

Catarrhal Conditions of the Female Genital Tract.

he following has been highly recommended as a very useful eral application to the mucous surfaces:

	Ichthyol	ʒi	4	
	Acidi borici	ʒss	2	
	Glycerini	℥i	32	

Sig.: To be applied locally.

The surfaces having been thoroughly cleansed they should be painted with the foregoing preparation, and when the cervix is involved, a tampon saturated with this solution may be placed *in situ* and allowed to remain for fifteen or twenty hours.

Calcium Chlorid for Menorrhagia.

Lafond, according to the *New York Med. Jour.*, prescribes calcium chlorid in daily amounts of from 20 to 30 grains by the mouth, using the following:

℞.	Calcii chloridi	gr. cxx	8	66
	Syrupi simplicis	℥ii	64	
	Aquæ	℥vi	192	

M. Sig.: One soupspoonful twice daily for eight days, beginning one week before the expected period.

M. Dalché recommends the following in the form of a pill:

℞.	Ergotin	gr. iss		09
	Quininæ sulph.	gr. 1/3		02
	Pulv. digitalis	gr. 1/6		01
	Pulv. colæ q. s.			

M. Ft. pil. No. i. Sig.: Take one such pill three times a day, beginning three or four days previous to the period and continuing throughout the flow.

Treatment of Neurasthenia.

Lemoine, in *Bul. Gén. de Thér.*, recommends the use of sodium phosphate, administered subcutaneously, stating that it is of service in supplying the phosphoric acid lost by the nervous system. He prescribes it as follows:

℞.	Sodii phosphatis	gr. xlv	3	
	Sodii chloridi	gr. xxx	2	
	Aq. destil.	℥iii	96	

M. Sig.: Inject 30 to 60 minims every other day.

Treatment of Gonorrhea.

As an injection the following is recommended:

℞.	Bismuthi subgal.			
	Pulv. acaciæ, āā	ʒii	8	
	Aq. destil.	℥iii	96	

M. Sig.: Use as an injection every two hours.

The following is employed by Cabot:

℞.	Plumbi acetatis			
	Acidi tannici			
	Zinci sulphatis			
	Cupri sulphatis, āā	gr. ii		12

M. Fiat tabella No. i. Sig.: Dissolve one such tablet in four ounces of water and use as an injection.

Treatment of Diabetic Pruritus Pudendi.

The physician should always look for diabetes, according to the *New York Med. Jour.*, whenever the pruritus is persistent and does not depend upon obvious local causes. In addition to the diet, if sugar is found in the urine, hot boric acid lotions are recommended:

℞.	Acidi borici	℥iss	48	
	Sodii boratis	gr. lxxv	5	
	Aq. destil.	Oii	960	

M. Sig.: Apply locally as hot as can be borne.

Specific Iritis.

The following is recommended to be given internally in cases of syphilitic iritis:

℞.	Hydrarg. biniodidi	gr. vi		36
	Potass. iodidi	ʒiss	6	
	Aq. destil	℥ss	16	
	Syr. aurantii q. s. ad	℥iii	96	

M. Sig.: One teaspoonful three times a day after meals.

Treatment of Appendicitis.

Prof. Bourget, as noted in *Merck's Archives*, outlines the following treatment for appendicitis when once it becomes established: The patient is put on a plain diet, and one-half an ounce of castor oil with 15 grains of salacetol (a salicylic acid derivative) is administered daily. Lavage of the stomach and of the lower bowel is productive of good. A quart of water containing some antiseptic solution may be introduced into the rectum. From three to eight ounces of olive oil may

117: It is justly considered an act of bad faith, or infamy or fiendishness, to deceive the enemy by flags of protection. Such act of bad faith may be good cause for refusing to respect such flags." The above was taken from the Army Regulations published the year before the United States became a party to the Geneva Convention. Yet, with a feeling of this sort published to the world, the hospitals do not have their own transportation. The United States, in the face of the Geneva Convention, still supplies the Medical Department with Quartermaster's transportation, tentage, etc., all because of the mistranslation of the French word "ambulance." The French regulation designates what constitutes an ambulance, giving the allowance of men, wagons, etc., which each class of ambulance shall have. Thus it is that the medical officer flying the Red Cross flag of the Geneva deceives the enemy, for the enemy does not know that all of these tents, wagons, horses, etc., which go to form an ambulance in the United States Army belong to the fighting force and that the fighting force is obligated, when their needs require, to take this material from the ambulances for their own use. They have the right to compel the Medical Department to again receive this property and again protect it from capture by flying over it the Red Cross flag of the Geneva Convention, when their necessity has passed. And hence it is that I have said that the Red Cross flag is a menace to the medical officer flying it over Quartermaster's property, which constitutes so large and important part of the ambulance or flying hospital of the United States Army.

So often has the thought been repeated to me that I am advocating a double-headed command, that I again feel called upon to state that I have insisted and still insist that the command continue to rest in the line where it belongs. He did not think that unless the condition was ungovernable he would use calomel. He certainly would not use it in an ordinary case of syphilis, for one could get along very well with inunction or internal treatment. He had never used the cyanid of mercury.

Dr. Gross, in reply, said that he had made a number of intra-venous injections and had always found them painful. One advantage of the intra-muscular injection was that the effect was more lasting. Regarding the pain he said he had used the injections considerably and only remembered one case where the man did not come back. The method should be tried faithfully in order to prove its efficacy.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Treatment of Cough and Pain in Tuberculosis.

The following is recommended in *Amer. Med.*:

℞.	Aq. Aurantii flor.	℥iv	128	
	Syr. chloralis			
	Syr. morphinæ, āā	℥i	32	
	Aq. laurocerosi	ʒiii	12	

M. Sig.: One dessertspoonful every hour.

Catarrhal Conditions of the Female Genital Tract.

The following has been highly recommended as a very useful general application to the mucous surfaces:

℞.	Ichthyol	ʒi	4	
	Acidi borici	ʒss	2	
	Glycerini	℥i	32	

M. Sig.: To be applied locally.

The surfaces having been thoroughly cleansed they should be painted with the foregoing preparation, and when the cervix is involved, a tampon saturated with this solution may be placed *in situ* and allowed to remain for fifteen or twenty hours.

Calcium Chlorid for Menorrhagia.

Lafond, according to the *New York Med. Jour.*, prescribes calcium chlorid in daily amounts of from 20 to 30 grains by the mouth, using the following:

℞.	Calcii chloridi	gr. cxx	8	66
	Syrupi simplicis	℥ii	64	
	Aquæ	℥vi	192	

M. Sig.: One soupspoonful twice daily for eight days, beginning one week before the expected period.

M. Dalché recommends the following in the form of a pill:

℞.	Ergotin	gr. iss		09
	Quininæ sulph.	gr. 1/3		02
	Pulv. digitalis	gr. 1/6		01
	Pulv. colæ q. s.			

M. Ft. pil. No. i. Sig.: Take one such pill three times a day, beginning three or four days previous to the period and continuing throughout the flow.

Treatment of Neurasthenia.

Lemoine, in *Bul. Gén. de Thér.*, recommends the use of sodium phosphate, administered subcutaneously, stating that it is of service in supplying the phosphoric acid lost by the nervous system. He prescribes it as follows:

℞.	Sodii phosphatis	gr. xlv	3	
	Sodii chloridi	gr. xxx	2	
	Aq. destil.	℥iii	96	

M. Sig.: Inject 30 to 60 *minims* every other day.

Treatment of Gonorrhea.

As an injection the following is recommended:

℞.	Bismuthi subgal.			
	Pulv. acaciæ, āā	ʒii	8	
	Aq. destil.	℥iii	96	

M. Sig.: Use as an injection every two hours.

The following is employed by Cabot:

℞.	Plumbi acetatis			
	Acidi tannici			
	Zinci sulphatis			
	Cupri sulphatis, āā	gr. ii		12

M. Fiat tabella No. i. Sig.: Dissolve one such tablet in four ounces of water and use as an injection.

Treatment of Diabetic Pruritus Pudendi.

The physician should always look for diabetes, according to the *New York Med. Jour.*, whenever the pruritus is persistent and does not depend upon obvious local causes. In addition to the diet, if sugar is found in the urine, hot boric acid lotions are recommended:

℞.	Acidi borici	℥iss	48	
	Sodii boratis	gr. lxxv	5	
	Aq. destil.	Oii	960	

M. Sig.: Apply locally as hot as can be borne.

Specific Iritis.

The following is recommended to be given internally in cases of syphilitic iritis:

℞.	Hydrarg. biniodidi	gr. vi		36
	Potass. iodidi	ʒiss	6	
	Aq. destil	℥ss	16	
	Syr. aurantii q. s. ad	℥iii	96	

M. Sig.: One teaspoonful three times a day after meals.

Treatment of Appendicitis.

Prof. Bourget, as noted in *Merck's Archives*, outlines the following treatment for appendicitis when once it becomes established: The patient is put on a plain diet, and one-half an ounce of castor oil with 15 grains of salacetol (a salicylic acid derivative) is administered daily. Lavage of the stomach and of the lower bowel is productive of good. A quart of water containing some antiseptic solution may be introduced into the rectum. From three to eight ounces of olive oil may be injected with this enema. The author uses ichthyol in the above enema in the strength of 4 to 1000. The first two enemas ought to be expelled entirely soon after being injected; later a small quantity should be retained. The enemas may be given morning and evening. During the interval flaxseed poultices are to be supplied over the right iliac region, and if tumor is large five to six leeches are indicated. After two or three days of this treatment the castor oil is replaced by salines as follows:

℞.	Sodii bicarb.	ʒss	2
	Sodii phos.	ʒss	2
	Sodii sulph.	ʒss	2
	Aquæ	Oi	192

M. Sig.: Five ounces three or four times a day.

Dr. Bourget is of the opinion that if the foregoing outline of treatment can be properly carried out that a good number of these cases of appendicitis would escape the surgeon's knife.

Treatment of Ulcers with Camphor.

Schulze, in *Clin. Moderna*, advises the following in the form of an ointment:

℞.	Pulv. camphoræ	gr. xv	1
	Zinci oxidi	ʒiiss	10
	Adipis	℥i	32

M. Sig.: Apply locally; or:

℞.	Pulv. camphoræ	gr. xxx	2
	Zinci oxidi	℥i	32
	Olei olivæ	℥i	32

M. Ft. unguentum. Sig.: Shake and apply locally; renew three times a day.

Combination of Trional and Paraldehyde as a Hypnotic.

Rapiteau, as noted in *Amer. Med.*, has observed that the combination of trional and paraldehyde gives a new hypnotic which is four or five times more active than trional alone, and which may be employed for a great length of time without the fear of forming a habit or of cumulative effects. He recommends its administration according to the following formulæ: First make a normal solution of the two drugs as follows:

℞.	Trional	gr. xv	1
	Paraldehyde	gr. xxx	2
	Olei amygdalis dulcis	℥ss	16

Mix the trional and paraldehyde, then add the oil and obtain a solution in a water bath.

As a draught:

℞.	Sol. trional et paraldehyde (normal)	℥iss	48
	Mucilaginis	℥iii	96
	Syr. pruni virg.	℥ss	16

M. Sig.: One tablespoonful at bedtime in cases of insomnia.

Each tablespoonful of the foregoing will contain 5 grains of sulphonal and 10 grains of paraldehyde.

The following is serviceable, to be given per rectum:

℞.	Sol. trional et paraldehyde	ʒii-iv	8-16
	Ovi vitelli uni		
	Lactis	℥ivss	144

M. Sig.: At one injection for an adult. In the form of a suppository:

℞.	Trional	gr. iii	20
	Paraldehyde	gr. vi	40
	Ol. Theobromæ	ʒi	4

M. Ft. suppository No. i. Sig.: To be given at night for an adult. For a child these preparations may be given in the following proportions:

℞.	Trional	gr. ¾	05
	Paraldehyde	gr. iss	09
	Ol. Theobromæ	gr. x	66

M. Ft. suppos. No. i. Sig.: At bedtime.

To be given in a capsule either to children or adults in the proper-sized doses, the following form of administration is recommended:

℞.	Trional	gr. ¾	05
	Paraldehyde	gr. iss	09
	Ol. amyg. dulcis	gr. x	66

M. Ft. cap. No. i. Sig.: One capsule three to six times a day.

AMERICAN.

3. **Laryngeal Tuberculosis.**—Donnellan concludes that primary laryngeal tuberculosis is hardly as rare as has been generally supposed and is quite explicable from a pathologic standpoint. He reviews the literature briefly, notices special points of diagnosis, etc., and remarks on the importance of bacteriologic and histologic examinations.

5. **Kidney Stone Diagnosis.**—The etiology, symptoms, etc., are first noticed by Macrae, who sums up the following as the principal aids as regards the diagnosis: General symptoms, local and reflex; examination of the urine, chemic, macroscopic and microscopic with the centrifuge; percussion over the affected side; the ureteral catheter and sound; inspection of the bladder and ureteral orifices; the segregator. In spite of the possible exception of the actual finding of a stone in the urine, we are not absolutely convinced that we have to deal with a nephritic calculus. Still another question arises as to whether we have one or more stones, and whether, if present, they are in the ureter, kidney substance, etc. He calls attention particularly to the importance of the *x*-ray, and believes the time has arrived when it becomes our duty to submit each and every case of an affection pointing to a pathologic nephroureteral condition to the *x*-ray. A few exceptions to this rule may be made in cases of nephritis following the exanthems, but even here, if the condition exists, the possibility of secondary calculi must not be overlooked. He does not believe in ureteral catheterization as a routine practice and retrograde sounding of the ureter should, he thinks, be relegated to the past.

7.—See also ¶27.

9. **Pulmonary Hemorrhages.**—Bonney has made a statistical study of his cases and reports his observations with special reference to the influence of Colorado climate on hemorrhagic cases of tuberculosis. His conclusions are: 1. Hemorrhage by itself, save with a few exceptions, furnishes no criterion upon which to base a choice of climate, the indications for high altitude in uncomplicated and in not too-far-advanced cases being highly imperative independent of this single manifestation. 2. An exceedingly small proportion of recurrences may be expected in Colorado, although not necessarily reflecting accurately the degree of ultimate improvement secured. 3. Recurrences are more likely to result, and that quickly, in those cases with hemorrhage immediately preceding arrival, and hence the wisdom of a short delay following the hemorrhage before leaving home and unusual precautions as regards rest upon arrival. 4. Primary hemorrhages are comparatively rare in Colorado and usually take place incident to a rapid, progressive, destructive change in cases already with hopeless prognosis, or as a natural result of some external assignable cause, which under proper régime could be avoided. 5. Hemorrhage, while less likely to occur in Colorado than at sea level, is nevertheless, as a general rule, more severe and associated with greater shock. 6. The avoidance of hemorrhage, particularly in the early months of Colorado life, demands a most rigid compliance with detailed instructions.

10. **The Tuberculosis Question.**—Among the subjects discussed by Arrowsmith are those of the heredity of the disease, which he seems to think is effective to a greater extent than many now suppose; at least this is the case as to hereditary predisposition. The method of infection which is alone capable of adequately explaining all the phenomena is that of ingestion, perhaps, in some cases, or a combination of inhalation and ingestion. Few people breathe continuously through their noses and a large proportion of the matters suspended in the inspired air is naturally deposited on the posterior wall of the pharynx and thence inevitably carried downward in the act of swallowing. The gastric disturbances which almost always antedate tuberculosis furnish the opportunity for the bacillus to enter the system by impairing the protective power of the normal stomach secretions. Infected food stuffs are also mentioned in this connection. The sum of our knowledge relative to the antecedent causes of phthisis now seems to be that, given a favorable soil, however produced, and the proper exposure, tuberculosis will result. Just what this soil is, is hard to say, but predisposition may be either inherited or acquired. The pre-tuberculous state is mentioned and it seems to him that all of us who have not tuberculosis, may be said to be in this condition. He fails to see in what the prodromal stage of phthisis differs from that of any other debilitating illness before the characteristic symptoms have appeared. He does not favor the use of tuberculin for diagnostic purposes, considering it not entirely reliable and possibly risky. The actual symptoms on which we may place reliance in reaching a conclusion as to the existence of tuberculosis are enumerated in the following order: Insidious perversion of general nutrition, with gastric and intestinal disturbance, which does not seem to have any distinctive characteristics. A persistent tachycardia is also an indication of commencing trouble in many cases, but one of the weightiest and most observable diagnostic symptoms in his experience is some abnormal variation of the temperature. He doubts the possibility of afebrile tuberculosis. When there is a persisting abnormal temperature range, there may be a question between tuberculosis and some form of malaria, and external applications of guaiacol will sometimes clear up the doubt by relieving the fever of tuberculosis, or leaving that of malaria uninfluenced. Thoracic inspection is of little account in the early stages, though a misshapen, unnaturally small-sized chest is a presumptive indication along with other signs. The apical involvement in the beginning of tuberculosis being to the basal in the ratio of 1 to 500, careful attention should be given to the condition of apex, and while auscultation of the anterior surface may be entirely negative, yet in the supraspinal fossa and along the inner bor-

der of the scapula we may find what we are in search of. In some cases small doses of iodin 3 to 5 gr. three times a day will help to determine the condition. Physical conditions are sometimes apparent during menstruation which are absent at other periods. Unnaturally clear transmission of heart sounds without consolidation is suggestive. Skiagraphy will be a much more prominent diagnostic measure in the future, he thinks, than at present. Occasionally laryngoscopy will reveal the trouble. He says, to recapitulate, that we are justified in assuming tuberculosis on the evidence of otherwise unexplained gastric and nutritive disturbances with persistent tachycardia and fluctuations of temperature, although slight, especially with an increase after exertion—particularly if the personal history gives a coloring probability. We may be absolutely certain of our diagnosis if in addition the slight physical signs mentioned are discoverable, and notwithstanding a history of cough and possibly hemoptysis, we may presumptively discard the probability of tuberculosis if these phenomena are absent. The prognosis of pulmonary tuberculosis is perhaps the most uncertain thing in medicine. He quotes Trudeau's statistics as showing the favorable prognosis in incipient tuberculosis, but the surest way to cure the disease is to prevent it and that the possibility of this is not Utopian is shown by the decrease where sanitary regulations are now enforced. A very important matter is that a patient should be assured of the protection given by an approximately normal condition of the upper respiratory tract. Catarrhal conditions, while they do not run into consumption, increase the liability to it. He condemns the indiscriminate prescribing of change of climate, notices the great success of outdoor life, and mentions a few remedies and methods, such as serum therapy, urea, etc., and protests against the use of cod-liver oil, heroin or other opium derivatives and cough syrups. He thinks, for the relief of cough, that the laryngeal syringe is a better method than any other that may be had. Antiseptic inhalations are of great additional utility.

12. **Consumption in General Hospitals.**—The dangers of crowding general hospitals with consumptive patients is remarked by Stone, who reports cases where tuberculosis seems to have been contracted from such associations. The patients in these wards are in a low state of vitality, especially susceptible to infection, and such infection has taken place.

14. **The Tuberculin Test.**—Casselberry reports a case which seems to him to indicate the decided value of this test as demonstrating the existence of tuberculosis in its bacillary stage. In cases of positive reaction, however, we must bear in mind syphilis, and also certain cases of sarcoma and carcinoma.

15.—See abstract in The Journal of September 28, p. 856.

16. **Panhysterokolpectomy.**—Complete prolapsus of the uterus and vagina is best treated, according to Edebohls, by panhysterokolpectomy, of which the essentials consist in complete removal of the uterus and vagina followed by operative obliteration or columnization of the bed of the genital tract. The tubes and ovaries are not disturbed if healthy; if diseased, they are removed. Obliteration and columnization of the bed of the removed uterus and vagina is effected by means of from seven to nine buried purse-string sutures of chromicized catgut placed about two to two and a half centimeters apart, and running parallel to each other. Each suture gathers the raw surfaces from the periphery in circular fashion and draws or purses them together in the median line. It is buried by being pushed upward toward the abdomen, while the next suture is being tied beneath it. The effect of the completed operation is to build a solid pelvic floor ten to fifteen centimeters in depth from peritoneum to perineum, and to establish broad apposition of the base of the bladder and the anterior surface of the rectum, conditions similar to those obtaining in the male pelvis. The patient is kept in bed for a week after operation. Recurrence of prolapse is impossible after a correctly and successfully performed panhysterokolpectomy. The operation is indicated in the severest cases of total prolapse, and more especially where other operative procedures have been tried and failed. The interference with further marital relations must be explained, and accepted by the patient prior to operation. In the case of a married woman the husband must also be consulted. Four cases have thus far been operated upon by the author of the operation, all with perfectly satisfactory results.

17. **Strangulated Hernia in Infants.**—Dowd reports a case of a child three months old in which there had been evidence of hernia with symptoms of strangulation, but the hernia was reduced apparently "en bloc" without relief of symptoms and relief was gained by operation. He calls attention to the difficulties of diagnosis in some of these cases. Babies can not talk, and cry for other things as well, and he analyzes the case to show the importance of different symptoms, which he gives in the following order: 1. Tumor; 2, vomiting; 3, constipation; 4, difficulty of urination; 5, restlessness and apparent pain; 6, constitutional depression. Early operation in all these cases has been apparently the greatest safeguard.

18. **Heredity in Tuberculosis.**—King holds the view that tuberculosis produces a relative immunity in the offspring, and that the heredity of the disease is correspondingly diminished. He thinks also that in his observation the average duration of disease in cases where there have been tuberculous parents has been longer and protection should be greater than in patients with no such ancestry. The conclusions which he offers are: 1. The percentage of consumptives having a tuberculous parentage is actually smaller than that having a non-tuberculous parentage, and much smaller than would be more than accounted for by the additional risk of infection to which the former class is subjected. 2. Tuberculosis in the parents renders to no inconsiderable extent an immunity to the disease in the offspring, an immunity which of course is but relative, and not sufficiently protective, but still demonstrable, as is shown by increased resistance to the progress of the disease and increased tendency to recover among this class.

20. **Gunshot Wounds of the Kidney.**—In a case reported by Roberts there was a self-inflicted pistol-shot wound in the front of the left breast, which passed through the depending mammary gland and then into the thorax. The bullet had missed the heart, perforated the diaphragm and injured the liver as it appeared at the time. There was no excessive shock, the pulse was slow, respiration rapid and temperature subnormal. Later, however, the temperature rose together with the respiration and pulse and the patient died after having been under observation about thirty-two hours. The postmortem revealed no injury to the thoracic viscera or intestines, but a groove-like wound was seen in the lower surface of the stomach, not perforating that viscus but perforating the upper end of the kidney, the bullet being found imbedded in the muscles of the back, opposite the first lumbar vertebra. Death was apparently due to slow bleeding of the wounded kidney and septic conditions of the wounded structures. The kidney wound was not suspected during life and operation was deemed hardly necessary.

21. **Gunshot Wound of the Stomach.**—Penn reports a case of gunshot wound of the stomach which was somewhat lower down than President McKinley's wound and was received when the stomach was full. The patient vomited freely as soon as shot, the vomitus consisting of the meal just eaten, together with quantities of clotted blood. He was fed exclusively on the mucilage of the cactus or prickly pear for fourteen days, which was allowed from the first, gradually returning to a full diet. There was never any decided rise of temperature and no evidence of peritonitis. The case is of interest as showing the unaided curative action of Nature occasionally in such cases.

25. **Muscular Atrophies.**—Mayer reports three cases illustrating the difficulties in the diagnosis of the different forms of this condition. One was apparently a case of fascio-scapular humeral dystrophy of the Landouzy-Dejerine type, but presenting certain peculiar features, it having run an acute course, being associated with pseudo-hypertrophy in the thighs and early appearance of contractures. The other two cases also present similar difficulties. He thinks we still cling to the idea of primary muscle disease in the want of more exact

knowledge as to the nervous involvement, which investigations have not yet satisfactorily demonstrated.

26. **Postdiphtheritic Urticaria.**—Walsh remarks on the occurrence of urticaria following the use of antitoxin to which it is credited, and reports a case in which urticaria followed a mild attack of diphtheria in which no antitoxin was used. He believes that careful study of the conditions produced by diphtheria itself will relieve the diphtheria serum from some of the accusations that have been made against it. It has been too much the custom to attribute every unusual symptom occurring after its administration to its agency, while some of these are undoubtedly due to anomalies in Nature's protective reaction against the toxins of the disease.

27. **Lane Lectures.**—This fifth lecture of Dr. Morris takes up the subject of tuberculous skin affections. He still recognizes the utility of the word scrofula as indicating a special delicacy of tissue, making it vulnerable beyond what is seen in the healthy state. He thinks the inoculation of lupus is a possible accident of vaccination, though it must be very rare. Other forms of skin tuberculosis, such as postmortem warts, the possibility of infection from ritual circumcision, tuberculous ulcers, scrofuloderma, lichen scrofulosorum and the various forms of tuberculides are also noticed.

28. **The Tonsils.**—Levy considers that the local causes of tonsillar disease are more important than the symptomatic causes and that the proper management of local conditions would prevent subsequent diseases. When the tonsils appear enlarged it has been the practice to remove them. He asks how we can preserve the protective functions which so many good authors recognize and how we may overcome the conditions and the etiologic factors for which the tonsils are responsible agents. In the majority of instances, especially in adults, complete enucleation of the diseased tonsil should be performed. The best method for this in adults is, he thinks, the galvanocaustic snare and where this is impracticable complete dissection of the diseased tissues may be accomplished by properly-constructed galvanocautery electrodes. In children amygdalotomy has its uses and advantages, and only in those cases where recurrence after a former amygdalotomy has taken place or where there is a diseased condition without hypertrophy, such as is seen in adults, should the more difficult and radical procedure be undertaken. In conclusion he insists that no operation on the tonsils should be performed simply because the structures are not absolutely normal in appearance, but only when distinct and well-defined symptoms exist, referable to these organs as the obvious cause.

33. **Ambroise Pare.**—Cumston's article is an interesting historical account of the life and times of Ambroise Paré.

34. **Cretinism.**—Millet gives a brief account of the facts in regard to cretinism, and also reports a couple of cases which had been treated with thyroid with benefit, but not with complete relief.

35. **Splenic Anemia.**—As far as it appears in this issue, Wentworth's article is a continuation of the discussion of the literature of the subject.

39. **Fibrinous Bronchitis.**—French reports and illustrates a case occurring in his own practice and reviews the etiology—which is not so characteristic—pathology, symptoms, prognosis and treatment of the condition. He considers the prognosis always grave, especially in the extremes of life, and much more serious when it occurs in the course of other affections than in the presence of fair health. He uses carbonate of creosote, in which he thinks he is the pioneer. He was led to use this by his observation of its action on bronchial secretion in other affections and also by the suspicion that tuberculosis might be present in the case. Improvement began immediately after its administration, and while a single case does not demonstrate much and the dose was small, he mentions it as being of some possible value.

40. **Nephrolithiasis.**—Ransohoff notices the diagnosis, treatment, etc., of nephrolithiasis and considers that the tenderness elicited in renal colic on bimanual examination of the kidney is an almost distinguishing feature, even in cases where enlargement can not be felt. He also thinks that uranalysis will do much in the diagnosis, and that decrease in the urine is sometimes of importance. Hematuria is always present, though rarely profuse. While profuse hematuria may follow acute kidney-stone colic, it more generally points to intermittent hydronephrosis, acute exacerbation of a chronic nephritis, and above all to malignant disease. If the colic has passed, the second symptom-group appears, such as pain spontaneously, or caused by pressure, urine changes, and general symptoms indicating the progressive septic changes in the kidney before it has come to proportional enlargement. While no one of these is pathogenic, their grouping is generally such that a correct diagnosis can be made. Pressure pain is much more important than spontaneous pain. Microscopic hematuria in the urine is also of importance. We should also employ cystoscopy to exclude vesical disease and to observe the changes around the ureteral orifice. He has had little positive results with radiography, and has removed quite large stones in which the method failed, but he thinks that in the future he may be enabled to get some positive results. When the colic fails to be followed by the passage of stones the indications for operation are strong, the case is parallel to that of gallstone, and trouble may ensue at any time. We should not wait for suppurative pyelitis or pyelonephritis to compel an operation as a life-saving measure. Nephrolithotomy should be a routine operation; its mortality is low and he thinks that a longitudinal section made along the convexity of the gland is less likely to wound the large vessels, and it need not be longer than necessary to introduce the exploratory finger, and compression of the pedicle of the kidney may be employed for short periods without any harm to completely control the hemorrhage. Drainage is seldom required. When in consequence of irritation from, and secondary infection due to stone, the kidney is enlarged and sacculated, nephrotomy and drainage are the procedures to be adopted, though the results are not so favorable. Nephrectomy is reserved for extreme cases where the disorganization of the kidney is such that it can not be recovered from.

42.—Ibid., p. 1726.

43.—Ibid.

44.—Ibid., p. 1725.

56. **Accessory Thyroids.**—Theisen reports and illustrates a case where there was a large tumor nearly the size of a hen's egg situated at the base of the tongue in a patient who, when young, had a very well-marked goiter and in whom at the present time there is no thyroid perceptible in its proper place. The troublesome symptoms seemed to be due to the size of the growth, but it did not seriously interfere with respiration. It was considered inadvisable on account of its size to operate, but thyroid medication was tried without bad effects and the tumor seemed to gradually decrease. He reviews a number of cases reported in the literature and remarks on the peculiar fact that all cases of accessory thyroid thus far reported in this situation have occurred in women.

69. **Malarial Nephritis.**—Ewing found in 14 fatal cases of malaria seen mostly in Montauk in 1898, extensive degenerative changes in the kidney, once the lesions of hemaglobinuric malaria, but comparatively few or any parasites in the renal vessels. The case here reported, however, shows the clinical symptoms of hemoglobinuric nephritis, with partial suppression of urine, and gives clear microscopic evidence of extreme massing of parasites in the kidney, apparently contradicting Marchiafava and Bignami's deduction that the lesions are not due to such localization, but to some toxic substance eliminated through the kidneys. In this case there was no doubt that the renal lesions were the principal features and that the case was one of true malaria in which the hemorrhagic character was due to massing of these parasites. The extreme degeneration of the cortical tubules is also a peculiar feature. He concludes as follows from the literature and his own

observations: "Microscopical examination of the kidneys of fatal cases of malaria has, then, yielded evidence of three main types of acute renal lesions occurring in this disease. 1. Acute degeneration of toxic origin, often reaching a degree in which exudation of blood serum into the tubules is added. This lesion is responsible for the vast majority of the cases of albuminuria in malaria. 2. An extreme form of acute degeneration, with focal necroses, numerous hemorrhages, and exudation into the tubules of the blood serum and blood pigments. This lesion is seen in cases of hemoglobinuric malarial fever, and it has not yet been found associated with an excessive number of parasites in the capillary vessels. 3. Massing of parasites in the renal capillaries, with extreme degeneration of parenchyma cells, multiple hemorrhages, and exudation of blood serum into the tubules. It seems certain that this type of lesion can occur only in severe estivo-autumnal infections. There is anatomical evidence that in the pernicious estivo-autumnal cases, the three types of lesions may be variously combined, but no good reason for believing that with the benign tertian infection occurring in this latitude any other than the first type can exist."

70. **Influenzal Mastoiditis.**—McCaw calls attention to the frequency of mastoiditis immediately following epidemics of influenza consequent on tympanic infection, which is, therefore, tympano-mastoiditis. The cases seem to be slow in recovery, the clinical picture being one of a very active suppurative process in a tissue of low vitality. In the severer type of cases he believes that la grippe is responsible for more cases of acute suppurative mastoiditis than either scarlatina, measles or diphtheria. From Perez's experiments he makes the suggestion that we may have one inflammation due to inoculation of Pfeiffer's bacillus alone, whereas in the other variety it may be associated with pyogenic organisms, and the virulence of each may be increased. As regards treatment, his best results have been obtained in the hemorrhagic type by rest in bed, free catharsis, leeching in front of the tragus and over the mastoid, and from douching of the canal every two hours. He is well aware that this method of hot douching has been criticised, but it has not been followed by bad consequences and has given him the largest percentage of recoveries. In the suppurative cases he uses early and free incision of the drum, warm douching every two hours with cleansing processes, catharsis and, if this does not relieve the patient in 36 to 48 hours, the case will be one for surgical interference. The amount of destruction which may take place in a short time is very notable. He has seen the entire mastoid in a purulent and necrotic condition with involvement of the facial nerve and facial paralysis *in one week* from the first ear symptoms. When we feel satisfied that pyogenic disease of the mastoid exists, our duty is to open the cells and not try to palliate or abort. In conclusion he emphasizes that we have two distinct types: "1. The suppurative, which invades the tympanum, antrum, and cells almost simultaneously in an unusually virulent and destructive process, which calls for early surgical treatment and in which abortive measures are contraindicated. 2. The hemorrhagic, with very pronounced symptoms at first, but which yields readily to abortive measures, and, in the writer's experience, only about 5 per cent. go on to suppuration requiring radical interference."

75.—See abstract in The Journal of October 19, ¶143, p. 1068.

77. **Anesthetics for Children.**—Wynkoop reviews the opinions and facts as regards the action of anesthetics in children and comes to the general conclusion that ether can be used with greater safety than any other anesthetic, while the combination with nitrous oxid is of value. Ether alone has few contraindications if properly administered.

80. **X-Ray in Lupus Vulgaris.**—Four cases of lupus vulgaris treated by the *x*-ray are reported by Greenleaf, who finds that this is the most satisfactory treatment for the condition and that repair begins almost immediately, that the danger attending the treatment is minimal, that the surroundings and general condition of the patient are important elements in the ultimate results, and that cases not subjected to surgical treatment react rapidly and ultimately recover, whereas, cases that have been surgically treated, react in a degree of slowness depending on the extent of the previous surgical interference.

82.—See abstract in The Journal of September 14, p. 711.

86. **Pelvic Appendiceal Abscesses.**—Four cases of pelvic appendiceal abscesses are reported by Baldwin, who thinks their opening per vaginam or per rectum is the simplest and most natural procedure and will lead to temporary recovery. If the appendix continues to make trouble, its removal in an interval operation will be attended with an absolute minimum of risk, while to open such an abscess by abdominal incision and across the open peritoneal cavity causes most serious risk and if peritonitis is obviated by extensive packing there is an almost inevitable chance of hernia.

89. **Counter Prescribing.**—Donaldson finds the druggist is better equipped to do counter prescribing than ever before. He has on his shelf proprietary remedies that save him the trouble not only of compounding, but also of selecting. The patient makes the diagnosis and the druggist has the remedy mixed, labeled and guaranteed. He took the trouble recently to make a list from a druggist's shelves of the diseases treated by modern counter prescribing. He found there 18 sure cures for consumption, 22 for rheumatism, 12 for gonorrhea, and special remedies for other diseases such as diabetes, etc., together with numerous shotgun mixtures, called pain-killers, blood-purifiers, or system-renovators that cure all diseases. He says it would not do to say to our patients "do not use patent medicines" for they would think it selfish in those advising them. The only legislation man can conceive that would mend matters would be one to require manufacturers to put the ingredients on each package. The physician should avoid prescribing proprietary remedies in the original packages as it teaches patients to treat themselves and gives them the little knowledge that is often dangerous. There is no need of telling the patient what drugs he is taking. If you listen in a drug store to the people you can hear them ask for quinin, morphin, ergot, calomel, bromid of potash and dozens of remedies of which they have obtained knowledge through the physician. Poisonous or dangerous remedies should be ordered off the market. Among these he mentions a "female regulator" that is put on the market, which is an ideal abortifacient so far as drugs are capable of acting in that way.

93.—See abstract in The Journal of September 21, p. 742.

98. **Nevus Linearis.**—The cause of the streaks in nevus linearis is discussed by Montgomery, who reviews the various theories and reports a case. The view that seems most nearly to fill the requirements is, that nevus linearis originates at an early stage in the development of the fetus when the embryonic layers are still a plastic mass. The disturbing agent, whatever its nature, usually affects what will later become the papillary layer of the skin and usually falls on one or the other side of the median line. Imagining the affected cells or groups of cells to lie in the plastic cells like currants in dough one can see that such a group lying in the region which later becomes the back of the neck, might be pulled toward the median line when the skin closes over the neural canal, and its individual constituents become scattered along this line as the fetus elongates. Another group situated over the place where the limb will afterward bud out, would be stretched along this line with the budding limb, and the line would tend to follow all the twists and turns of the limb as it grew out, exactly as Kaposi has so graphically described. This view would explain the frequent unilaterality of the affection, and its occurrence along the fissures of the body, as along the branchial clefts. There are some objections to this view, but he concludes that, on the whole, it is the most probable one that can be offered.

104. **Convalescence from Functional Nervous Disorders.**—The management of the convalescent stage of functional nervous troubles is discussed by Pearce, who insists on the importance of mental methods, though not dwelling on this phase of the subject extensively. He thinks the patients must be schooled

or educated into self-control. The physical care, that is, the necessity of rest and of exercise to a limited degree, is also mentioned as important, and he thinks the most desirable forms of exercise in this stage of neural disorders are to be in a general way different from those of the ordinary routine of the patient's life; that is, keeping him away from his ordinary mode of thought and from thinking about self. If the patient can be kept off his feet to a certain extent it will be advantageous. As for the adjuvants to mental rest we have intestinal antisepsis, colon flushings, diet, hypernutrition, massage, electricity and avoidance of excitement.

114. **Antrum Abscess.**—Pierce thinks that the ostium and accessory openings of the antrum of Highmore have not been utilized sufficiently in the treatment of empyema. After a few remarks on the anatomy he describes his method of treatment by washing out the antrum and reports a number of cases. In conclusion he says: "1. There is a strong evidence to warrant the belief that in diseased antra, accessory openings are more frequently found than in healthy antra. 2. In a certain number of cases the ostium may be used to irrigate the antrum. 3. We should in all cases, whether for diagnosis or treatment, try for the ostium or accessory openings before resorting to surgical puncture, whether through the inferior or middle meatus, the canine fossa or alveolar process. 4. It is of no importance whether the opening through which we irrigate be the ostium or an accessory opening."

115. **Diagnosis of Adenoids.**—A number of conditions that may cause confusion and lead to diagnosis of adenoids in very young children are enumerated by Chappell. He has not, himself, been able to demonstrate to his satisfaction the presence of adenoids in young infants. Among the conditions which he mentions are lymphatism which may cause enlargement of the cervico-bronchial glands in which the mucosa of the trachea and bronchi are principally affected and which may often be present at birth. In all degrees of obstruction beyond the uvula the infant is obliged to remove the nipple from the mouth every few minutes to get air, but when the obstruction is lower down, the nipple may be retained in the mouth during feeding. When stenosis of the tracheo-bronchial tract exists, sonorous and asthmatic chest sounds may be heard while the child is nursing, which cease when the nursing is over. Lithemic infection is usually confined to the superficial tissues, but may spread beneath the pharyngeal aponeurosis, forming a small retropharyngeal abscess. When infants with a family history of gout or rheumatism have recurring attacks of rhinitis, pharyngitis, trachitis and bronchitis there may be indications that suggest adenoid obstruction. Syphilitic or gonorrheal rhinitis may produce nasal obstruction and congenital atelectasis may cause respiratory symptoms which may sometimes be mistaken for adenoids. Digestive disturbances causing vomiting and regurgitation of milk curds lodging in the nasal passages also give confusing symptoms. Large tongue, though rare, may be a serious cause of respiratory obstruction and Billard claims there is a non-traumatic esophagitis, which may cause considerable pressure on the trachea and larynx. Chappell has had patients in which he could make no other satisfactory diagnosis. Hypertrophic rhinitis is common in children though general among those of more advanced age. Septal spurs, foreign bodies in the nose, etc., should all be looked for in this connection.

118.—See abstract in The Journal of September 28, p. 850.

124. **Pernicious Anemia.**—From a review of the facts of this condition White concludes that we have in these cases to deal with some agent which increases blood destruction and interferes with blood regeneration both in the marrow and the lymphatic glands, and that it is not of the common order of the infections, from the different responses which the organism makes to it. The resistance of the individual probably plays a very important rôle and he thinks that from the analogous parasitic condition the agent is more likely to be an animal poison or possibly a ptomain than anything else. In short, he holds that we have here a special poison choosing for its seat the whole blood circulation.

128. **Tetanus.**—From the fact that tetanus germs are susceptible to cold and that the reduction of temperature interferes with their vital activity and sporulation, Rogers has employed ice applications in incipient cases where the tetanic conditions had already spread to the trunk, neck and extremities. The arrest of progress in the development of the disease was manifest in a few hours and after four days there was a gradual lessening of the convulsive symptoms which ceased entirely on the fifth day. The patient then suspended of his own accord, the ice treatment. The symptoms returned in thirty-six hours, but with diminished force. On renewal of the treatment the good results followed even more quickly and three days later treatment was permanently suspended. A second case is also mentioned where similar treatment was instituted with like results.

131.—See abstract in The Journal, xxxv, p. 1425.

134. **Gastrostomy.**—In the patient described by Meriwether there was a carcinomatous tumor of the pyloric end of the stomach and also a cardiac mass obstructing that region. Gastroenterostomy was performed with the Murphy button and gastrostomy as follows: An external opening had been made by an incision of four inches over the inner edge of the left rectus joined by a transverse one from its upper end extending to the left for three inches. A rubber tube was next inserted in about the middle of the anterior surface of the stomach, emerging at the end of the transverse incision through the skin. Two catgut sutures were applied below the opening in the stomach, then six sutures, each one-fourth of an inch further above and below the tube than the preceding one, the sutures being half an inch apart and passing through the peritoneum, then through one-fourth of an inch of the two external coats of the stomach, then over the tube, then through the stomach as before, and then through the peritoneum. A last suture was passed through the two coats of the stomach and then under the tube, making something like a purse-string suture. All these were of catgut. When tied they brought peritoneum to peritoneum and formed a fluid-tight, funnel-shaped canal leading from the skin to the opening in the stomach. The peritoneum was stitched around the portion of the tube where it emerged and the skin and muscle closed by through-and-through sutures of silkworm-gut. One fine catgut suture was placed through the tube where it entered the stomach to anchor it. The patient was fed before leaving the table after the stomach had been washed out. She came out of the operation well, gained in weight and about four months later appeared to be in good condition. Three months after the operation she removed the tube and refused to allow it to be permanently replaced. At one time it was left out thirty-six hours, but there was no difficulty in reintroducing it. Five months after the operation, however, the old difficulty in swallowing returned and she gradually sank, living, however until November. The button came away on the eighty-first day.

141. **Widal's Reaction.**—Pothier considers the positive Widal reaction of great value and always to be considered as indicating typhoid fever, while a negative result does not mean anything *per se*. While several negative results may strongly point to a non-typhoid case, the clinical course of the disease is a better criterion. He mentions a method of diagnosis used in the New Orleans Charity Hospital, consisting in making cultures from the urine of patients, which is collected in sterile tubes after careful asepsis of the parts and, if necessary, by catheterization. Two or three loopfuls from this urine are planted on an agar-culture tube or in bouillon, incubated for twenty-four hours and then tested with a known typhoid serum as to whether or not it is typhoid. As a rule these cultures are pure.

142. **Spinal Analgesia.**—Delaup briefly reports 22 cases and describes his method of using cocain injections. He has seen but little inconvenience from the operation; perfect analgesia was obtained in 90 per cent. and partial in 9 per cent. In 41 per cent. there were not the slightest subjective or objective symptoms. Nausea occurred in 36 per cent. and there was a slight general malaise for a few minutes. Headache was

the most common symptom, noted in 50 per cent. of the cases, never lasting more than from twelve to twenty-four hours; temperature elevation was of short duration, never above 102 F. Pronounced malaise, chills, depression, and in fact shock, was observed in but one case. Increased pulse-rate is a very unreliable symptom, the nervousness of the patient is liable to account for it. If there is febrile or irregular heart action small doses of strychnin or nitroglycerin may be administered hypodermically. It is a good plan to give a preliminary subcutaneous injection of strychnin with a little morphin. Involuntary defecation took place only once. He is not sure whether the disagreeable symptoms are the result of the drug itself, or the result of disturbance of the nerve centers from increase or decrease of intraspinal pressure. But the method can never be used with a certain class of patients, like children and nervous women, in which the loss of consciousness is essential. While he does not consider it an ideal anesthetic, or that it in any way replaces the general method, it has a special sphere of usefulness in genito-urinary and rectal surgery and surgery of the lower extremities. In many cases of pulmonary, cardiac or renal disease it would be far less dangerous than chloroform or ether.

152. **Vaccination.**—Runyon has little faith in glycerinated virus. He has found it ineffective in many patients and some patients he has known to suffer from subsequent smallpox when exposed. He believes that the humanized virus is best, though it is not certain that its immunity persists longer than that from points. The next best is bovine on bone slips. He thinks that children should be vaccinated in infancy and again in five years, and revaccinated when liable to be exposed to smallpox. In this way they will avoid serious effects from the operation which sometimes occur when it is delayed until ordinary immunity is completely lost.

153. **Hemaglobinuric Fever.**—With the two cases here reported Shropshire remarks in regard to the origin of the condition. He doubts entirely the effect of quinin in producing it, and considers the disease as a primary malignant fever due entirely to the action of the plasmodium. He uses quinin freely in cases with good results.

154.—This article has appeared elsewhere. See The Journal of September 7, ¶64, p. 663.

FOREIGN.

British Medical Journal, October 5.

Shock in Abdominal Operations. George A. Hawkins-Ambler.—The author does not attempt to give a definition of shock, but quotes a number that have been offered, among the more scientific of which he includes that of Erichson, who describes shock as being due to a general exhaustion of the nervous centers consequent upon extremely violent afferent impulse, and that of Goltz, quoted by Crile, as a vasomotor paralysis resulting from mechanical violence. While we have not a satisfactory definition, we have learned more in regard to the subject and he refers to Sherrington's work, pointing out that operative interference in a healthy animal is followed by a certain degree of apoplasmia or drying up of the blood. The degree of apoplasmia depends to some extent upon the severity of the lesion, but is always considerable and must always be taken into our calculation. With this increase in specific gravity, Sherrington also observes an increase in the hemoglobin content of the blood and increase in the number of chromocytes per unit volume. The ratio of leucocytes to chromocytes was always increased and there were alterations in the proportion of other blood cells. The different nerve cells also give important evidence. Crile quotes Hodge's investigations on microscopic investigations of nerve cells at rest and in fatigue, showing that repeated afferent stimuli exhaust the bulb; the equilibrium of the nervous system is more or less upset. We must differentiate also between shock and acute sepsis, which offers similar symptoms. Some cases of apparent shock are really cases of acute sepsis, and if we look in the mediastinal glands and other organs we shall find evidence of this. Special points, however, here given as important elements in the causation of shock are the matters of time and engorgement and dilatation of the splanchnic area. In abdominal operations in which we are operating in the midst of vasomotor nerves and ganglia which control an immense venous area, the dilatation of which must mean a remarkable difference in the blood pressure throughout the circulation, the effect on the heart might be immediate. The author refers especially here to Crile's work, one of the latest, most practical and suggestive on the subject. Bearing these things in mind, what are we to say about the treatment? The best he thinks is preventive. We should prepare for shock and minimize it by the very best methods. The old-fashioned plan of preparation of patients by a short holiday is an excellent thing in its way. Improvement in the general health should be looked after. We sometimes starve our patients too much before operation and with hot douches, drastic purges, etc., reduce them so that the addition of fear is all that is necessary to bring them to a state of semi-collapse before they get on the table. An empty stomach, desirable as it is in many cases, may be procured at too great a cost. Preliminary injection of saline solution into the rectum before operation may add a great deal to the patient's comfort and improve the chances, or a little brandy with hot water may be of advantage. The question of anesthetics is important also. Any anesthetic may have its action in increasing the shock. Crile finds that he prevents shock by cutting out the afferent impulses, blocking the nerves with cocain, but this is not so easy in abdominal surgery. Hawkins-Ambler's opinion is that the element of time is the most important; Lawson Tait's success he attributes largely to his rapidity in operating. The question of the temperature of the operating room, preliminary preparation, etc., is important, and he says it is a good plan to flood the peritoneum for a time with hot saline solution in protracted operations. The next point is thirst; if we take thickening of the blood as evidence and standard of shock the intense thirst is an indication of it and the practice of starvation in the hope that the thirsty tissues may be compelled to lap up the exudates into the peritoneal cavity to prevent sepsis, and peritonitis may very easily be overdone. Shock should be met by replacing fluids withdrawn from the circulation, by restoring to the dried blood the more spacious circulatory medium in which its cells may move without increasing the friction coefficient. If there is no vomiting, fluids may be given in small quantities by the mouth. Hot water can be sipped, and the very act of slowly sipping has been shown to improve the pulse by antagonizing the inhibitory action of the vagus. Minute doses of brandy and water also sipped at intervals have a very sedative effect. Saline injections given per rectum, or if necessary hypodermically into the veins are advantageous. The difference between shock and hemorrhage is perhaps after all not so great; it is largely the loss of oxygen carriers in the latter case. If the blood is pooled in the splanchnic veins, both plasma and corpuscles are removed from active usefulness. The introduction of saline will largely remedy this. With flushing of the peritoneum to prevent sepsis we shall also promote its resisting powers, and he insists, therefore, on the use of saline solutions. As for drugs, they must be secondary, and as to maintenance of body heat by wrapping the patient, etc., he has but few words to say. Very small doses of strychnia are of value, and also small doses of morphin and atropin given hypodermically before the patient leaves the table at the close of a severe operation.

When and How to Operate on Uterine Fibroids. William Duncan.—The author believes the following conditions call for interference in uterine fibroids: Hemorrhage, when there is severe menorrhagia or metrorrhagia and the uterus is enlarged by fibroids. The first thing to do is to dilate the cervical canal and explore the uterine cavity for polypi or submucous growths. This should be done before resorting to more radical measures. He does not believe much in operating through the vagina, and removal of the appendages to stop hemorrhage or arrest the growth of tumor. Hysterectomy can, he believes, be best carried out by the intraperitoneal method, which has the advantage of showing whether there are any adhesions of the bowel or omentum to the tumor, or whether the Fallopian tubes contain pus. The second indication for operation is when the tumor is causing pressure on the bladder, the rectum or cervical nerves. When it can be pushed above the brim of the pelvis and kept there, operation may be avoided, but when it can not, nothing but hysterectomy is of use. When a fibroid tumor takes on a rapid growth this is due either to cystic or mucoid degeneration and always calls for hysterectomy without delay. Lastly, when a fibroid complicates pregnancy the risks are greatly increased, though the position of the growth has much to do with this. If the fibroid is situated at the upper uterine segment or is subperitoneal and not impacted in the pelvis, pregnancy and labor may in many cases proceed naturally and terminate favorably. Such cases should not be interfered with. When it occurs in the lower portion of the pelvic, obstructing the pelvic brim, we have either to empty the uterus, to perform hysterectomy, or allow the case to go on to full term and save the child by Cesarean section and then remove the uterus. He would feel disposed in such cases to try abortion first, and if that failed to resort to hysterectomy. The dangers of shock with heart failure and tympanitis from intestinal paralysis are mentioned. In order to prevent the first it has been his custom to administer hypodermically 3 drops of liquor strychniæ, B. P., three times a day for a week prior to and a week after the operation. A nutritive enema after the operation is administered every four hours, with the addition of one-half an ounce of brandy if the patient is very feeble, and, if the flatus is not freely escaping twenty-four hours after operation, an ounce of spirits of turpentine in a pint of hot water is passed high up in the bowel. This may be, repeated in twelve hours. He attaches great importance to this and to the strychnia injections. As regards the operation itself, he ties off both the ovarian and uterine arteries on both sides before cutting down the peritoneal flaps; thus preventing loss of blood to any great extent. After the flaps are reflected down to the level of the tied uterine arteries, the cervix is cut across and the tumor removed. Any oozing points in the cervix are tied with catgut, and then the peritoneal flaps are carefully brought together with fine silk in a continuous Lembert suture. Where the tumor burrows between the layers of the broad ligaments and a large cavity is left after their removal, instead of draining this, he carefully whips the sides together from below upward by a continuous suture after all oozing has been controlled and the cases do perfectly well. The abdominal wall is sewed up by three layers of continuous suture, fine silk for the peritoneum, coarse silk for the sheaths of the recti and coarser for the skin. In this way he feels sure that the occurrence of ventral hernia later on is prevented.

On a New Gynecological Position. F. Jayle.—In this note in the *British Medical Journal,* Jayle points out that Scultetus had recommended what is really the Trendelenburg position before 1645, and there was also a drawing in a still earlier, 13th century publication, showing the position during the operation for hernia. What he specially calls attention to, however, is the combination of the ordinary position of the speculum or of the lithotomy position and of the Trendelenburg position. In order to obtain this it is necessary to have a balancing table with a system of shoulder rests, holding the patient in position without securing the lower members, which remain free. This can be used either for examination or operation. It has the advantage of throwing back the intestine, of determining by the entrance of air the dilatation of the vagina, which becomes almost vertical, and finally of stretching the anterior vaginal wall. It greatly facilitates the exploration of the tubes and ovaries, especially the uterus. The introduction of the speculum is very easy and exploration of the vaginal wall is easy, for it is sufficient to depress the perineum either with the finger or with a valve speculum in order to get a good view of the anterior walls always, and very frequently of the cervix. For operations it must be used combined with the lithotomy position. If the patient be put only in a half declivity, vaginal operation becomes much easier. The anterior wall is stretched out and with a weight valve you can press down the perineum, and no assistant is necessary for holding the valves. He specially calls attention to the utility of this method in vesico-vaginal fistula operations.

Ovarian Pregnancy. Hastings Gilford.—The published cases of ovarian pregnancy are reviewed by Gilford, who finds 16 cases and 12 probable ones, or 28 altogether. He thinks that many have been reported under the names of blood cysts, rupture of the ovary and ovarian apoplexy. He asks how conception within the Graafian follicle can take place. One explanation is that the sperm cell enters through the aperture produced by the bursting of a follicle and impregnates an ovum which has not yet escaped. The opening then heals over and pregnancy goes on in the sealed sac. The other is given by Schroeder, who thinks that the spermatozoa may possibly penetrate through the coat of the follicle at its most attenuated part. The former of these, he thinks, is the more probable, though it does not necessarily follow that the rent in the follicle closes.

Further Report on the New Operation for Prolapsus Uteri, with Notes of Forty Cases. J. Inglis Parsons.—Four years have elapsed since this author first adopted the operation here described. It does not interfere with pregnancy; the general idea is to strengthen the bands within the broad ligaments and enable them to hold the uterus up. The principle of treatment is very simple. It consists of taking advantage of Nature's reparative powers. The idea is simply to furnish a stimulus for the formation of lymph which repairs the ligaments when a joint is dislocated, and after thinking the subject over he decided to try this in uterine prolapse, to help Nature to repair the overstrained broad ligaments. The choice of re-agents requires consideration; it should be aseptic, the effect should be entirely local, and any absorption that takes place should be harmless. Sulphate of quinin most nearly fills all these conditions. When injected into the cellular tissue of the arm it appears to be precipitated and causes an effusion of lymph which remains for some weeks. It is also aseptic, and is a tonic to the general system if absorption occurs. A solution of this is injected into the cellular tissue of the broad ligaments from the vagina. The uterine arteries and veins lying on the inner side of the broad ligament are not in the way if the needle is inserted at the right point, as also holds true of the ureters, while the outer two-thirds of the lower half of the broad ligament contains no veins or arteries of any size or importance, and can be freely laid open from the vagina without having to tie a single vessel. The operation takes only a few minutes, and is not risky if performed with precision, proper care and antiseptic precautions. There is no rise of temperature as a rule. It is essential that the point of the needle should be within the folds of the ligaments and within the cellular tissue. An anesthetic is of advantage, though not absolutely necessary. The patient is placed in the lithotomy position and the parts aseptically prepared, the rectum, of course, having been emptied as well as the bladder. The posterior wall of the vagina is pressed down with a Sim's speculum, while the anterior is held up by a retractor. If they roll together in folds and block the view of the cervix two lateral retractors may be required. The injection is made with a thin, long, straight, rigid nozzle syringe and a needle about one inch in length and rather thicker than a hypodermic, and is passed on each side through the vaginal wall, taking care the direction of the needle is perpendicular to the base of the broad ligament and parallel to the long axis of the uterus. The needle should always be tested as the quinin solution corrodes it and it may then snap off. Some pain is felt after the injection, varying in different individuals. When the patient is lifted into bed the uterus should be well anteverted bimanually. A cup and stem india-rubber pessary secured by bands around the waist is inserted to keep the uterus well up until effusion of lymph has taken place. It will then be removed, as the uterus at the end of four or five days is held up by the effusion. The strength of the solution should be attended to. If too strong it will cause suppuration, or if too weak will not be sufficiently stimulating. For the past twelve months he has used a solution of 1 in 5, and the average amount inserted is 30 to 45 minims on each side. The temperature usually remains normal. There may be a slight aching in the pelvis for a few days. It does not follow that one injection is sufficient, the condition of the parts, weight of the uterus, duration of prolapse and labor afterward will have to be considered. None of his patients have ever had the least signs of cinchonism, though in most instances as much as 12 grains have been injected at one sitting. He tries to keep his patients at rest after the operation for a certain time as much as possible. Of the 40 cases that he has operated on and which he tabulates, only 2 have relapsed, 4 have been only improved, while the other 34 patients have remained well.

Presse Medicale (Paris), September 18.

Ocular Disturbances or Deformities in the Insane. M. De Montyel.—Mignot found that only 19.5 per cent. of 82 insane persons he examined had normal eyes, and that in 41.4 per cent. a deformity of the pupil coincided with some ocular disturbance. In the present communication, the results of the examination of 77 insane subjects showed that only 16.8 per cent. were normal in this respect. The pupils were unequal in 37.7 per cent. In certain subjects the ocular deformity and disturbances were very pronounced, but in the majority they were slight.

Revue Hebd. de Laryngologie (Bordeaux), September 21.

Ozena in Sinusitis. J. E. Torrent.—In five cases of sinusitis, the clinical symptoms of ozena were presented in a pronounced form but they all vanished as the sinusitis yielded to treatment. Torrent believes that true ozena is a morbid entity, rebellious to treatment, but that all the symptoms can accompany an ordinary sinusitis and simulate true ozena, unless the actual cause is discovered in the sinusitis.

Syphilitic Peripheral Paralysis of the Muscles of the Pharynx. Charles.—A hitherto healthy child of 3, with apparently healthy parents, manifested symptoms of pharyngeal paralysis, such as are usually attributed to a known or unnoticed diphtheria. In the absence of any probable source of diphtheritic infection, Charles instituted specific treatment, with the cure of all the symptoms in twelve days. The father confessed later that he had a "disease with pustules" before marriage.

September 28.

Lithiasis of the Submaxillary Gland. Lafarelle.—The pains caused by the presence of calculi in the submaxillary gland are frequently ascribed to the throat and ear, as they radiate in all directions. Two cases are described, one in a woman of 40, the other in a man of 45. Besides the functional and physical signs of salivary lithiasis, the paroxysmal pains, the alternating swelling and subsiding of a submaxillary tumor, the discharge of purulent saliva from the tumor on compression and palpation of a hard substance, the complete permeability of Wharton's duct for the catheter indicated the location of the trouble. The preferable operation is the systematic extirpation of the submaxillary gland, as the acute inflammation caused by the calculi is certain to be followed by sclerosis of the gland. Even if the inflammation is slight, the gland should be removed to prevent recurrence. The operation is simple and easy. The facial vein has to be severed, but the facial artery and the hypoglossus nerve are left intact. The insignificant scar is hidden by the lower jaw.

Varices of the Base of the Tongue as a Sign of Cancer of the Esophagus. Lefrancois.—Painful varices at the base of the tongue were the only lesions discoverable in three patients who complained of dysphagia. Each one died within a year from cancer of the esophagus. Lefrancois queries whether the varices may not have been the first clinical symptom of the cancer below, or whether their presence was a mere coincidence.

Semaine Medicale (Paris), September 25.

Syringomyelia of the Medulla and Pons. Raymond.—In the case described, motor paralysis of all the limbs, with spasmodic paralysis of the legs, dissociated sensibility and kyphoscoliosis coincided with other symptoms which indicated a lesion in the medulla, atrophy of the left half of the tongue, neuro-paralytic keratitis of the left eye, lateral nystagmus and anesthesia of the left trifacial nerve and of the mucosa of the back of the throat. Raymond's pupils have been studying the lesions in the autopsies of cases of syringomyelia during the last six years. They have found that the first lesion occurs in the region around the ependyma, near the central canal of the spinal cord, gradually invading the posterior cornu, the base of the anterior cornu and the adjacent portions of the white tracts. The lesion may range from an insignificant fissure with compact walls to an immense cavity involving all the elements of the cord and medulla. The spinal meninges may or may not be affected. Microscopic sections have fully demonstrated the inconstant relation of the syringomyelic gliosis with the central canal, and its special fissure-forming development. It is evident that certain cases of hypertrophic cervical pachymeningitis, but not all, belong in the domain of syringomyelia. Syringomyelia is, therefore, a definite affection like sclerosis in plaques. Its essence is a specific gliosis, produced independently of any other pre-existing lesion or affection of the spinal cord, such as myelitis or sclerosis, by the proliferation of the neuroglia in response to multiple pathogenic causes. This gliosis is to be distinguished from glioma and from cavity-forming myelitis. The syringomyelic lesion may spread laterally or longitudinally and consequently may affect the most varied anatomic and functional systems, inducing equally variable associations of symptoms. It may simulate more or less deceptively almost any one or all of the affections due to disease of the spinal cord or medulla, from progressive muscular atrophy to tabes and leprosy. But there is always a fourfold group of morbid phenomena more or less evident in syringomyelia: trophic disturbances, dissociated superficial sensibility and a tendency to scoliosis and paralytic motor troubles. The lesions are incurable, but as long as they are restricted to the spinal cord, long survival is possible. When the symptoms indicate that the medulla and pons have been invaded, a rapidly fatal termination is inevitable.

Simultaneous Appearance of Mosquitoes and Malaria. A. Billet.—This communication from Algeria states that a careful watch was kept for the first appearance of anopheles, to determine if it coincided with the first cases of malaria. The mosquitoes began to arrive June 15, and between June 26 and July 10, seven soldiers who had arrived during the winter, were received at the hospital affected with malarial fever, the first malarial patients of the year.

Two Cases of Actinomycosis in the Parametrium. C. Fehmers.—A woman in good health and menstruating normally, noticed pains in the right half of the abdomen and discovered a tumor. Three weeks later she entered the hospital and, with a diagnosis of pelvic peritonitis, the posterior cul-de-sac was incised and drained. The patient was much relieved but returned a month later on account of a lumbar abscess communicating with the initial pelvic focus. Actinomyces were found in the pus, and iodin treatment was commenced. A series of abscesses formed in the lumbar region and abdominal walls, with a stercoral fistula. After eighteen months of treatment, the patient seemed to be practically cured, although the fistula still persisted. She returned a year later with recurrence of severe symptoms, and died in collapse during the laparotomy. The intestines and uterus were found solidly fixed and altered by the lesions and adhesions. The patient had had one pregnancy years before. In the second case, the patient was a multipara, with abundant and prolonged menstruation. During a convalescence from typhoid fever, a sudden pain attracted attention to the right hypogastrium and a tumor was discovered, assumed to be a suppurating ovarian cyst. At the laparotomy the tissues were found much infiltrated and a focus of pus containing actinomyces was discovered. Vigorous local and general iodin treatment was instituted, and the patient seems to be completely recovered. The cases are reported in detail in the *Nederl. Tijdschr. v. Geneesk.* of June 29.

Deutsche Med. Wochenschrift, October 3.

Treatment of Anthrax. F. Schultze.—Strubell described last year a case of malignant pustule just below the eye, which he cured by the application of hot compresses, renewed every ten minutes, night and day, supplemented by injections of 12 c.c. of a 3 per cent. solution of carbolic acid. Schultze relates a similar case of malignant pustule also just below the eye. The treatment was restricted to the application of a sublimate 1 to 1000 dressing, in a 70 per cent. alcoholic solution over the ulcerating portions. Quinin was given in 30 cg. doses every three hours during the febrile period, and 30 cg. of naphthalin were administered occasionally on account of the diarrhea. The patient progressed even more rapidly to recovery than Strubell's patient, although the symptoms were if anything more serious. The intoxication is the chief danger in such cases, and it presents a clinical picture closely resembling that of typhoid fever, aside from the local phenomena. The bronchi and kidneys as well as the intestines were involved and the cerebral symptoms were the same as those observed in typhoid fever.

Electric Light Sweat Baths. Krebs.—As the results of experiences and observation at the hydrotherapeutic institution connected with the University of Berlin, Krebs announces that incandescent light baths induce profuse sweating more rapidly and at a lower temperature than is required for hot-air baths. This effect is probably due to the heat rays in these lights. The arc light is much less effective. Patients with organic heart defects may find these baths injurious.

Prognosis of Diabetes and Tuberculosis. G. Oeder.—It is usually supposed that tuberculosis in a diabetic subject runs an unusually rapid course. Oeder describes the case of a diabetic patient who has exhibited unmistakable symptoms of pulmonary tuberculosis for six years, but both diseases have seemed to be in *statu quo* for several years.

Monatsschrift f. Geb. u. Gyn. (Berlin), July.

Metastases in the Ovaries in Case of Primary Abdominal Malignant Disease Elsewhere. E. Kraus.—The 11 observations collected include 3 in which the primary carcinoma was located in the stomach, and 7 in the gall-bladder or biliary passages. The patients had been operated on for the easily diagnosed tumor in the ovaries, which was merely a metastasis of the small primary tumor elsewhere which had been completely overlooked. The slight symptoms on the part of the alimentary canal had been attributed to reflex irritation. The patients bore the ovariotomy well, but succumbed later to the gradual evolution of the primary tumor, which could easily have been removed at the same time if its presence had been suspected. Kraus urges search for a primary tumor when both ovaries form cancerous, knobby tumors, and section shows the characteristic peripheral arrangement of the tumor masses. If the ovaries are found even slightly enlarged and hard, during the extirpation of a primary neoplasm in any abdominal organ, they should be considered suspicious, especially if nodules are discovered in Douglas' pouch. He reports experiments which demonstrate that cancerous elements are able to penetrate into the intact ovary from its outer surface, even in the case of rabbits' ovaries, which are smaller and less exposed to danger of penetration than the human ovary.

August.

Stimulation of Labor by Intrauterine Rubber Bag. G. Hauffe.—The advantages of the rubber bags used by Hauffe are that when distended with fluid, they are comparatively hard, and prove an energetic stimulus to the contractions of the uterus, much more so than the soft bags ordinarily employed for this purpose.

September.

Diagnosis of a Vesicular Mole. W. Poten.—The diagnosis of a vesicular mole is sustained by the lack of elastic tension in the walls of the uterus, which feel like soft clay on palpation. There are also, in case of a vesicular mole, peculiar contractions of circumscribed portions of the uterine walls, occurring spasmodically and subsiding completely. In one case the uterus seemed to contain a hard myoma, the size of a fist, in an otherwise soft organ. Half an hour later, the supposed myoma had vanished to reappear again in another portion of the organ. The patient is not conscious of these contractions. In three cases described, the patients were in the sixth to the ninth month of pregnancy. In another case, the mole had ceased to proliferate, remained in the uterus like an inert foreign body and was finally expelled. In two other cases the symptoms had some analogy with those described, but a macerated fetus instead of a mole was found in each instance.

Heart Defects and Pregnancy. O. Fillner.—The prognosis of pregnancy in case of cardiac defect is not so serious as has been generally assumed, judging from the experiences at Schauta's clinic since 1892. They include 94 patients with 305 births, out of a total of 30,613 deliveries in the Maternity. Fillner has also collected 140 cases from the literature, with 520 births. The results show that with appropriate treatment the overwhelming majority of the patients pass through the stress of childbirth without any special disturbance or even a suspicion of their cardiac defect. Delivery is frequently longer than usual. In all cases of uncompensated cardiac defect a more or less extensive ring of necrosis is found at the edge of the placenta. The pregnancy was spontaneously interrupted in 20.2 per cent. of the cases, with a mortality of 25.5 per cent. for the children. Only a very small percentage succumbed to the heart trouble; 6.3 per cent. at Schauta's clinic and .9 per cent. of all those systematically investigated. Mitral stenosis alone seems to afford an unfavorable prognosis. In other conditions, it is not the kind, but the extent of the defect which is the decisive element. Only in the rarest cases is any unfavorable influence on the heart defect from the pregnancy to be discovered. In case of compensated defect, premature delivery is not indicated unless the patient was in peril of death in previous childbirths. In case of uncompensated defect premature delivery is indicated only when treatment has no chance of success; otherwise internal treatment should be applied first and after improvement has been obtained, the pregnancy should be artificially interrupted. Mitral stenosis, and the complication of a cardiac defect by chronic nephritis or tuberculosis, require more vigorous procedures. In case of compensated defect, the bougie alone should be used. If a fatal termination is imminent, the fetal membranes should be ruptured which will give temporary relief, and may prove useful in case of edema of the lungs. It is better not to wait too long before applying the forceps in case of an uncompensated cardiac defect. Marriage need be forbidden only in case of pronounced disturbances in compensation, or mitral stenosis or a defect complicated by tuberculosis and chronic nephritis. If severe disturbances in compensation appear during the course of a pregnancy, future pregnancies should be forbidden, and in case of deadly peril during a pregnancy, the patient should be rendered sterile.

Muenchener Med. Wochenschrift, September 24.

Senile Pruritus of the Tongue. E. Baumgarten.—During the last three years Baumgarten has had occasion to observe two cases of pruritus of the tongue, occurring in elderly women, with all the characteristics of senile pruritus of the skin, and in one case followed later by cutaneous manifestations. A long array of remedies was tried, but without avail, the pruritus persisting unaffected. Some local or general cause can usually be found for tongue troubles and the diagnosis of senile pruritus should not be made until after the exclusion of affections of the stomach or intestines, constipation or other general cause, including the dry catarrh of the throat which is a frequent companion of the menopause, and usually coincides with dryness, smarting and burning sensations in the tongue. The latter may also occur in cases of disturbed menstruation. Pure neuralgia of the tongue is extremely rare, but neurasthenic disturbances involving the tongue are not infrequent in both men and women. In three cases Baumgarten diagnosed.

tabes from the pains in the tongue alone, confirmed by the later course of the disease. Pains and smarting of the tongue, especially when accompanied by ptyalism, are very suspicious of commencing paralysis. In other cases, the symptoms noticed in the tongue were the precursors of some local affection. Varices of the base of the tongue are cauterized by some physicians, but this is useless unless the general cause inducing them is removed.

Lysol Intoxication. G. Burgl.—Two cases are related in which pure lysol was administered to a child by mistake, and eighteen cases of lysol intoxication in the literature are reviewed. They show that prompt use of the stomach pump was followed by the recovery of all the patients thus treated, while the neglect of this measure was almost invariably fatal. The solution should never be stronger than 1 per cent. for external application and .5 per cent. for irrigating internal cavities. It should never be used long at a time. One death has been known from the external application of pure lysol on the intact skin. If it is administered internally, the minimal dose should be taken as the standard, and it should never be given except for a brief period and better not at all, in case of children or feeble patients. In the 18 cases collected, the intoxication occurred in 13 from internal and in 5 from external use of the agent. Nine of the patients died, 5 children and one adult after internal administration, and 2 adults and one child after the application of pure lysol externally, by mistake for the 1 per cent. solution that had been ordered. The largest dose from which the patient recovered was 60 gm., taken by a woman, and 25 gm. by a 4-year-old child. The smallest dose that proved fatal was a teaspoonful, about 4 to 5 gm. of pure lysol, in children from 5 days to 8 years old.

Tamponing the Abdominal Cavity with Air to Arrest Threatening Hemorrhage. G. Kelling.—A series of experiments on dogs and cadavers are described, showing the harmlessness of this measure and its efficacy in arresting threatening internal hemorrhage. The accumulations of ascitic fluid in the abdomen prove that it will tolerate considerable stretching. Tests on seven cadavers of adults between 37 and 87, demonstrated that the abdomen could be thus inflated to a pressure of 150 mm. mercury or 1.5 meter water without laceration of the peritoneum. The apparatus consists of a T-shaped glass tube connected by a rubber tube with the mercury column at one end: with a double rubber air bulb at the other, and with the puncturing needle on the third branch. The tube connecting with the needle is interrupted by two bottle-shaped bottomless glass tubes, connected by a short rubber tube. The broad part of these bottle-shaped tubes is loosely packed with cotton to filter the air. It is injected under close supervision of the respiration and heart action, until a negative pressure of 30 mm. mercury or, better still, of 50 mm. is obtained. The stomach, bladder and rectum are liable to evacuate their contents by the mechanical effect of the pressure, for which preparations must be made. In case of hemorrhage of the stomach, some substance to promote coagulation should be administered by the mouth before injecting the air. After numerous tests, Kelling found pulverized chalk mixed with milk, the most effective local measure for this purpose. It can be administered by the mouth in not too small amounts. He has never had an opportunity to apply this tamponing measure in the clinic, but his tests on large dogs have been so successful that he is confident it will prove extremely useful in practical application to patients. He warns that the subjective sensations are no criterion, but that the circulation and pulse must be carefully watched. The first part of his report was published in The Journal of October 12, p. 1010.

Brazil-Medico (Rio de Janeiro), September 1.

Death After Spinal Tropa Cocainization. D. de Almeida.—The patient in the case reported was 80 years of age, and had eaten nothing for three or four days. The operation was undertaken for the relief of incarcerated inguinal hernia, and 2 cg. of tropacocain were injected in the subarachnoid space, in a 2 per cent. solution. A few minutes after the operation had been completed, the pulsations of the heart gradually grew less and less perceptible, and the patient died with no other symptoms except this quiet failing of the heart action.

Proofs in Favor of the Transmission of Yellow Fever by Mosquitoes. E. M. Ribas.—The superintendent of the board of health at Sao Paulo, Dr. Ribas, is convinced of the plausibility of the mosquito theory and suggests that mosquitoes may bite during the hours of early morning, while the subjects are still sleeping, as the culex teniatus is not a night insect. He describes a convincing incident in the outbreak of yellow fever at Sao Paulo in 1900. No cases had been known in town for a long time, when an Italian ship arrived from Rio, January 2, and one of the crew suffering from yellow fever was received in the hospital. Fourteen days later, five other yellow-fever patients were admitted. All were sailors from two vessels moored along the quays near the Italian ship. The culex teniatus is found in the street that fronts the quays, and the row of ships formed as it were, a row of dwellings on the seaward side of the street, where the culex could easily penetrate. Other sailors were affected soon afterward; all being men who had lived a number of months in the town without previous infection. The epidemic was arrested after it had attacked 400 out of the 50,000 inhabitants of the town. The sanitary measures applied in the infected ships and dwellings probably destroyed the infected mosquitoes, and thus contributed to the arrest of the epidemic.

Cirugia Contemporanea (Mexico), September 15.

Intra-Arachnoid Cocainization in Mexico. R. Norma.—Eighty-seven operations have been reported in Mexico, done under spinal cocainization. No threatening by-effects were noted in any case; in 31 no symptoms of any kind were observed, in 32 the usual slight headache, vomiting or nausea. In one case an overdose was used, with the symptoms to be anticipated in such a case. In two other cases, one a hysteric and one a much debilitated hemiplegic, the temperature rose to 104 F. in one, and syncope occurred in the other. Norma considers that the simplicity and prompt efficacy of this method of surgical analgesia commend it particularly for alcoholic subjects.

Cronica Medica Mexicana (Mexico), October 1.

Mercury for Injection Into Vessels for Radiography. D. Garcia.—Mercury answers all the conditions required to render even the most delicate macroscopic capillaries visible in radiography. Garcia has devised an apparatus for the purpose, a glass canula with two stopcocks and graduated receptacle, which enables the injection to proceed without admixture of air. Radiographs of anatomic specimens thus prepared were remarkable for the wealth of details, as even a thickness of one-tenth of a millimeter casts a clear shadow.

Value of Ferric Chlorid in Therapeutics. J. B. Hernandez.—The remarkable anticongestive, antiphlogistic, antisuppurative and anti-exudative action of ferric chlorid is proclaimed by Hernandez. He considers it superior to all other substances for the treatment of superficial inflammatory or catarrhal lesions. It is ineffective in profound inflammation and actually injurious in chronic inflammation But it has proved remarkably beneficial in his experience in erysipelas, phlegmons, smallpox, eczema, herpes zoster, and catarrh of the vagina, cervix and conjunctiva. It is also valuable in acne rosacea, anthrax, hemorrhoids, gastritis, otitis, rhinitis, rectitis, gonorrhea and catarrhal metritis of the fundus. He uses the chlorid in "Pravaz's solution," and appends to this communication numerous case—reports to substantiate his statements.

Cronica Medica (Lima), xvii, 301 and 302.

Causal Agent of Verrugas Peruana. A. L. Barton.—The researches of three years have been crowned with success, Barton announces, by the discovery of the bacillus derived from the spleen, blood and mesenteric ganglia of patients suffering from verrugas. Inoculated into animals it produces the typical symptoms of the clinical disease. It is extremely motile, stains readily, is not pyogenic, and is more pathogenic for the mule than for the dog, the only animals experimented on.

Queries and Minor Notes.

TEACHING OF PHYSICAL THERAPEUTICS.

Philadelphia, Oct. 8, 1901.

To the Editor:—In an editorial in The Journal of Oct. 5, 1901, p. 916, you refer to the subject of the "teaching of physical therapeutics," and state that there are at present being published in English and German, systems of therapeutics in which physical agents especially are discussed. I shall be under many obligations to you if you will kindly indicate the publications to which you refer, because I am very much interested in this subject and desire all the information with regard to publications obtainable.

B. H. D.

Ans.—P. Blakiston's Son & Co. are publishing a "System of Physiologic Therapeutics," edited by Dr. S. Solis-Cohen; there is in process of publication a "Handbuch der Physikalischen Therapie," edited by Goldscheider and Jacob (George Thieme, Leipsic). Further, there is a German periodical, *Zeitschrift für diätetische und physikalische Therapie*, edited by Leyden and Goldscheider, and there is also published in Great Britain a *Journal for Physiological* (or Physical) *Therapeutics.*

AKOUPHONE.

Concordia, Kan., Sept. 18, 1901.

To the Editor:—In The Journal of April 6, 1901, p. 982, is a description of the akouphone and akoulalion by J. R. Hutchinson, before the New York Academy of Medicine. Can you give me the address of the manufacturer? I have a child I desire to try one on.

W. F. S.

Ans.—Address the Akouphone Company, 43 E. 20th St., New York City.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., October 3 to 9, inclusive:

William J. Calvert, lieutenant and asst.-surgeon, U. S. A., leave of absence granted.

W. Fitzhugh Carter, major and surgeon, U. S. A., will accompany the Third Battalion of Engineers to Washington Barracks, D. C., and thereafter return to his proper station, Fort Totten, N. Y.

Max F. Clausius, contract surgeon, previous orders directing him to proceed to his home for annulment of contract, revoked.

John Ryan Devereux, lieutenant and asst.-surgeon, U. S. A., from duty at Washington Barracks, D. C., via Tampa, Fla., to Havana, Cuba, for assignment in the Department of Cuba.

Clyde S. Ford, lieutenant and asst-surgeon, U. S. A., former orders directing him to proceed to Fort Morgan, Ala., revoked; he will repair to Washington, D. C., and report to the Surgeon-General for instructions.

Joseph H. Ford, lieutenant anc [illegible] A., from Fort Washington, Md., to duty at [illegible] D. C.
